growths, tendrils, bad leaves and blossoms. Ventilate early and carefully, avoiding draughts and depressions of temperature.

Cucumbers and Melons in Pits and Frames.—The plants should have the primary growth stopped at the second leaf before or after planting out, and the resulting shoots again pinched at a similar extent of growth, then allow the growths to extend a foot or more before again pinching, and stop the thus divided shoots at 1 foot from the sides of the frames. The plants will show fruit plentifully under such circumstances, and then stopping one joint beyond the show will throw vigour into the fruits. Little water will be required, nevertheless maintain the soil in a moist state. Cover the lights with double mats at night, and see that the linings are regularly attended to, renewing as required. Prepare materials for making fresh beds and linings. Three parts Oak, Spanish Chestnut, or Beech leaves and one part stable litter make the best beds at this time of year. In a few days there will be warmth in the materials after mixing and moistening; if not, turn the whole, sprinkling with water or liquid manure, so as to moisten the mass, and when in good heat turn the heap outside to inside, two turnings being necessary at intervals of about four days to secure sweetened material. Maintain the bottom heat at 85° to 90°, taking care, however, to prevent overheating.

Peaches and Nectarines.—*Early Forced House.*—The fine forcing weather has improved the fruit wonderfully, it being well advanced in the first swelling, and the very early varieties near commencement of the stoning process. Early and gradual thinning having been attended to, there will be little more than the necessary quantity. Vigorous trees are the most uncertain in stoning, as they are prone to rush into wood growth, and then throw off the fruit. The best remedy for this is lifting, thus concentrating the forces on reproduction. Keep the temperature during the stoning process as equable as possible, as sudden checks by draughts of cold air in the daytime and too high a temperature in the night may prove disastrous. The night temperature may range from 60° to 65°, but 5° less is safer, particularly in severe weather, and in the daytime 70° to 75° with sun heat, and about 65° by artificial means when the atmosphere outside is cold and the sky overcast. Secure the growing shoots to the trellis as they advance, keeping those retained to attract the sap to the fruit stopped at the second or third joint. Red spider must be kept in check by syringing with water at the same temperature as the house, and if brown aphid or thrips appear fumigate carefully when the foliage is quite dry. Take care that the soil does not become too dry.

Succession Houses.—Disbudding and tying-in must be attended to before the growths become too long, disbudding gradually. If the fruits have set thickly—more than a dozen on a foot length of shoot—thin them soon after the remains of the blossoms are cast, removing the smallest fruits, those on the under side of the branches, and those badly placed, leaving three to five of the best. These in turn should be reduced to two or three when not larger than marbles, and finally to one or two, this thinning taking place when the fruit is the size of Walnuts. The temperature may then be raised to 55° to 60° at night, and 60° to 65° by day, from fire heat, ventilating from 65°, and insuring 75° from sun heat, closing moderately early in the afternoon, but avoiding a close atmosphere.

Strawberries in Pots.—The earliest plants now ripening their fruit should have a drier and more freely ventilated house, but there must be no sudden change or the fruit will not finish well. For swelling the temperature should be 65° at night, and 70° to 75° by day, advancing to 80°, 85°, or 90° with sun, and plenty of atmospheric moisture, and after the fruit changes colour the atmosphere should be kept cooler and drier, so as to insure flavour. The second early plants having set the fruit and been thinned, a matter too frequently neglected, will be swelling freely, as the thinning enables the plants to produce fine fruit. Half a dozen berries of even and large size are better than a dozen small; but regard must be had to the variety, for half a dozen on La Grosse Sucrée, still unsurpassed as the surest very early forcer, has its equivalent in a dozen on Vicomtesse Héricart de Thury, Royal Sovereign requiring about the same amount of thinning. Give liquid manure copiously as often as required, examining the plants twice, and in bright weather three times a day for the purpose. Plants in vineries and Peach houses come on successively, and need not be moved except to meet special requirements. Strawberries of the larger varieties placed in cool lean-to or span-roofed houses or frames afford grand fruits a fortnight to three weeks earlier than those in the open ground.

THE KITCHEN GARDEN.

Jerusalem Artichokes.—Thanks to the mildness of the winter green vegetables have been plentiful, and there has been less demand for Artichokes. Another season the case may be different, and there ought to be no neglect in planting as many roots as usual this month. Too often Artichokes are left on the same plot of ground year after year; not replanted, but allowed to spring up thinly and irregularly, with the result that the crops are light and the tubers of poor quality. They ought to have fresh ground, preferably a plot outside of a walled-in garden, and this should be prepared as carefully and thoroughly as for Potatoes. Open drills 6 inches deep and 3 feet apart, and in these plant either medium sized tuber or sets formed by cutting strong tubers, arranging them 1 foot asunder. All that is further necessary is to hoe among the plants when well through the ground, and to mould up Potato fashion. Any tubers not wanted for planting ought now to be lifted, cleared of sprouts, and stored in sand at the foot of a north wall or fence for future use.

Borecole.—These are early running to seed, and if neglected will soon be of no further service. The young shoots ought to be gathered frequently, this causing the formation of later supplies, and which will most probably be found acceptable. Asparagus or Buda Kale are

frequently of the most value in May, but will not give succulent "greens" so late unless kept closely gathered from in March and April. Borecole requires a rather a long period of growth, but if the seed is sown in the open ground during this month the plants will usually be forward enough for putting out by the time the ground is ready for their reception.

Brussels Sprouts.—The sprouts on these must also be kept closely gathered, or otherwise the supply will soon fail. Those who have deferred cutting the hearts will find some close sprouts among the lower leaves, or enough to form good dishes. Since the introduction of improved strains there is less need to raise the plants so early as formerly, but if seed is sown now, either in boxes or beds inside frames, abundance of plants suitable for pricking out on sheltered borders in April should result. Where close cropping is practised the plan of arranging short-topped early maturing varieties of Potatoes 3 feet apart, and planting Brussels Sprouts midway between the Potatoes directly after they have been moulded up, is recommended for adoption. If Veitch's Autumn or other early Broccoli are sown with the Brussels Sprouts, and treated similarly, the plants will produce superior hearts in close succession to autumn Cauliflowers.

Cauliflowers.—The autumn-raised plants are somewhat forward, and those not well established under hand-lights will not transplant readily. The smaller plants in frames or seed beds would experience the least check when finally planted out if first established in small pots under glass. Any raised early this year ought to be quite large enough for pricking into boxes, or for placing either singly in 2½-inch pots or in pairs in 4-inch pots. Sink the stems in good loamy soil, and arrange the plants not far from the glass in gentle heat. Before they become badly root-bound all ought to be hardened somewhat, and planted either in rough frames, hand-lights, at the foot of sunny walls, or on warm borders where they can be roughly protected.

Carrots.—If the first favourable opportunity is taken of sowing seed of an early Horn variety on a light or well prepared south border, this may result in the production of numerous early pullings of tender young roots. A close look out should be kept for the plants, dusting these over with soot and lime directly they show through the soil, repeating the dose occasionally to save them from slugs. The seed would germinate more surely and quickly if given the benefit of a little bottom heat. It is not yet too late to form a shallow hotbed of fresh and partially exhausted leaves and stable manure. Surface the bed with about 6 inches of fine sandy soil, enclosing this with boards. Sow the seed thinly, roughly protecting with mats or trebled fish netting supported by stakes.

Onions.—The most economical, and in the end the most profitable method of culture, is to raise all the plants required in boxes under glass early in the year, and to plant out on well prepared ground when they are about 4 inches high. Not having sown the requisite amount of seed in the manner indicated, an early opportunity should be taken of sowing in the usual way, late raised plants frequently failing to mature properly. Onions ought to have a site that has been early manured, and either trenched or dug in time for the soil to be pulverised by the action of drying winds, frosts, sunshine, and rain. If it can be got into a finely divided state without any extra trouble the manuring and digging may be deferred to nearer sowing time with advantage. After having made the bed fine to a good depth, give a surfacing of one peck of soot per square rod to the heavier soils, and to light, less retentive ground that amount of soot, 4 lbs. of common salt, and a bushel or more of gritty road scrapings per rod. Stir these dressings into the surface with a fork, trample the ground, level, and make a fine surface with a rake; then draw drills half an inch deep, and not too narrow, sowing the seed thinly, but not in a fine line in these, fix with the foot, and smooth over with a rake. Onions will pay well for this extra trouble, the soot and salt in addition to being good fertilisers also acting as preventives of the Onion maggot.

Herbs.—Perennial herbs pay for replanting every second or third year. If a change of border cannot be afforded, lift all the plants, manure the ground freely, and dig deeply prior to dividing and replanting the herbs. Sow seed of the hardier annual kinds, and also Thyme and Sage.

THE BEE-KEEPER.

NOTES ON BEE MANAGEMENT.

IN his endeavour to withdraw from the untenable position in which he is put, "G. H." attempts to place the saddle on the wrong horse, and in doing so, although evidently unaware of the fact, corroborates what we have stated in these columns on several occasions—namely, that many bees are lost whilst on the wing during inclement weather, and through various other causes. These may be briefly referred to here, as being applicable to this season. Although the weather has been exceptionally mild, there is now every appearance of a cold spell of weather setting in, and in that case, as was lately explained, bees that are placed in large hives, and have been encouraged to breed during the winter, will on the appearance of severe frost gradually contract their cluster, and if the brood nest has been unreasonably enlarged many bees will be lost.

If during the short days of winter or late in the spring the ground is covered with snow, and the sun is shining brightly during the middle of the day, the bees will be tempted to leave their hive, and many will alight on the snow, never to rise again, as they will be numbed, and become a prey to the birds. Thousands may be lost in this manner, and steps should always be taken to prevent it. Shortness of stores, too, is a frequent cause of losses in the apiary. We have known on more than one occasion of the whole of the bees leaving their hive from this cause.

"G. H." evidently had other thoughts on this important subject when he penned the interesting note at midwinter—namely, on December 24th, 1896, wherein he says, "A good queen will lay from 3000 to 4000 eggs per day." Again he says, "On March 3rd the bees covered nine frames 18 inches by 9 deep, and by the 1st of April or the first week in May the bees would crowd the hive." Now, after another year's experience, he informs readers that the weather was responsible for the loss of thousands of bees in the early months of the year; and doubtless the colony was less in numbers the first week in May than it was supposed to be two months earlier, thus clearly demonstrating in a practical manner the fallacy of endeavouring to have a hive crowded with bees, as above, in the first three months of the year.

FERTILE QUEENS.

The queen is now only credited with laying the above number of eggs during the height of the season, whatever this may mean. It may mean one month, or six months, more or less. No mention was made of this in his original note on the subject, so it was only reasonable to suppose, after reading of the colony early in March, and the weight of honey that was expected—namely, 350 lbs.—that the said queen was laying eggs to order. No allowance was made for that important factor in bee management, the weather, so it was not surprising that the bees in general, and this colony in particular, did not come up to expectation. We have often proved the value of a good fertile queen. These are usually at their best the second year, and if placed at the head of a strong colony of bees, say from 7 lbs. to 14 lbs. in weight, a surplus will be stored at a great rate. This illustrates in a marked manner what we have often endeavoured to explain—namely, the greater the number of workers in a hive so will the surplus be in proportion. The queen, too, will fill the combs in the brood nest at a rapid rate, perhaps even more so than "G. H." gives her credit for. But everything must be favourable.

WEIGHT OF HONEY OBTAINED.

At page 70 "G. H." mentions the fact of obtaining 180 lbs. of honey from a hive, and that in a district where there was no white Clover within two miles of his apiary. In a later communication (page 136) he says, "Six miles from my home, in a good Clover district, three of us are interested in a bee house that holds twenty hives." It would be interesting to know how the bees and the surplus they obtained during the past season from this favoured locality compared with those not so favourably situated, and from what source the above surplus was obtained. In reply to "Warwick" (page 136), "G. H." says it is recorded that Mr. William Cowie had hives with fifteen frames, 20 inches by 8½, and two tiers of supers filled by the 31st May." Has "G. H." asked himself the question seriously from what source the above large yield of honey could be obtained so early in the year? If he does, we are inclined to think he will not repeat it, but place the paragraph on the same level as the wonderful yield of honey exposed in these pages by "A Border Bee-keeper" not long ago.

HIVES AND FRAMES.

If "G. H." will approach the question of hives and frames with an open mind on the subject we have no fear of the result. We cannot imagine anyone being serious in supposing that half an inch in the depth of a frame makes any difference in the practical management of bees. In previous notes "G. H." has recommended frames 8½ inches, in others 9 inches in depth. The length of the frame has varied somewhat, but we again repeat that it is of little consequence whether the frames are deep or narrow, long or short, if ample room is provided for the bees when they require it.

The size of frames most generally used is 14 inches by 8½ inches. This is known as the Standard frame, because it was chosen by the British Bee-Keeper's Association, after many experiments, as the most suitable size for use in this country. We do not say it is better, but it is certainly as good as any other, and as it is an advantage in many ways to have a recognised size, both in frames and hives, it is advisable for a bee-keeper to have all his frames interchangeable in his apiary, and success will follow if managed on rational lines.—AN ENGLISH BEE-KEEPER.

TRADE CATALOGUE RECEIVED.

Dobbie & Co., Rothesay.—Agricultural Seeds.

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Yellow Wax for Grafting (J. F.).—The yellow wax is a superior class of beeswax, this being sometimes called yellow to distinguish it from white wax. The ordinary beeswax will answer, but some so called is made from other substances than are produced by bees.

Syringing Cucumbers (A. R. W.).—Syringing with a fine spray underneath the leaves of Cucumbers to prevent spider is not injurious to the plants if done at the proper time. If done frequently, regardless of weather and temperature, more harm than good would result. The best time for syringing is early in the afternoon of bright days, closing the house at the time, so that the temperature may rise to 80° or more, and the leaves get dry before nightfall. Some growers syringe also in the morning, except in dull, damp weather.

Size of Cucumber House (Wakopa).—There is nothing gained by having Cucumber houses small. It costs very little more to build a house 12 feet or 15 feet in width than it does to erect one only 10 feet wide, and the extra amount of roof room more than compensates for the outlay. Very few market growers now erect the 12 feet Cucumber houses, as they have found the 15 feet more suitable for their purpose. Excellent crops of Cucumbers were grown in houses of the dimensions named, and it is easy to prevent trouble by the atmosphere being too dry. Small 10 feet wide houses, however, only require three rows of 4-inch pipes.

Small Cauliflowers (Tiller).—You wish to know why your earliest Cauliflowers only come the size of a man's fist, and ask if this indicates want of tillage. Though the richer the land is the larger the heads will be, you cannot make giants out of a naturally early and small variety. What you have been growing is probably one of the first early selections from the Erfurt, and valuable they are because of their precocity. We have seen in very rich soil eight or nine heads such as you describe to the square yard, plants a foot asunder, so the aggregate crop was not very bad. If you want heads larger, but somewhat later, try the Erfurt Mammoth. This is succeeded by the Early London, and for a late supply you will find the largest of all in Autumn Giant, of which we understand a London firm requires as a yearly supply the produce of 500 acres for pickling.

Artificial Manures (C. B. W.).—Previous pages were filled on the arrival of your note. You will see, however, that the subject is dealt with, and have something to show in return for what was shown to you. The same kinds of artificial manures do not produce the same effects in differing soils. Those who use them can only relate their experience. If one person find them of service he has good reason to speak in their favour; if another use them carefully with no practical results, he can only say what is true. His land and crops did not need them. It seems surprising that you have not tested the matter for yourself. A primer—the "Chemistry of the Garden"—is just published by Macmillans. We have a review of it in type, but it is crowded out. You cannot do better than procure a copy at once. It can be had through a bookseller for 1s. You will see what the author, Mr. Cousins, says in favour of experiments over analyses, and he is well acquainted with both.

Judas Tree (H. F.).—This tree is so named because of the allegation of its being the tree on which a world denounced traitor hanged himself. It is a fanciful tradition. Botanically it is *Cercis siliquastrum*, and belongs to the natural order Leguminosæ. It is known popularly as the Red Bud or Love Tree. It is a native of the South of Europe and a large area of Asia. It is grown in standard form in shrubberies in the south of England, and, where the wood ripens well, is covered with short racemes of purplish red Pea-shaped flowers in advance of the leaves. These are 3 or 4 inches wide, and somewhat kidney shaped, pale bluish green on the upper surface, and sea green below. It is a low growing tree, 15 to 20 feet high, with a flattish round spreading head, distinct from all others, both when in flower and full leafage. It might succeed as a standard in a sheltered position in your garden. Not very far distant from you we remember one being grown against a wall facing west, trained up the side and over the top of a doorway entrance from the kitchen garden to the flower garden of an old Ivy-covered mansion. If it is not there yet some modern "improver" must have cleared it away.

Arisæmas (*G. O. Lingard*).—If you turn to page 197 you will there find an illustration of *A. Wrayi*, together with a brief note, which will be of assistance to you. If you want further information write again.

Heating Water in Tanks (*Herts*).—We know of no better way of heating the cold water in tanks than that of having a hole drilled in the hot-water pipes close to the tank and putting a tap in the same. By turning on the tap sufficient hot water can be run into the cold to heat the latter to the required temperature. If a small tap will not allow the water to run quickly enough, use a large one. Obviously, the hot-water pipes must be filled as soon as enough water has been drawn out.

Making Edgings for Flower Beds (*Novice*).—The method usually adopted to have raised edgings to flower beds brought out to the edge of the grass is as follows:—First, the beds are well filled with suitable soil for planting, and at the time the edges are thoroughly moistened with water from the rose of a watering can. They are then brought out to the extreme limits required and trodden firmly, after which a practised workman pares off the inequalities with a sharp bright spade, leaving a perfectly smooth and even surface. The plants to be inserted, such as *Echeverias* or *Alternantheras*, are carefully planted without disturbing the smooth surface. These will assist in the support, and retain the upright character throughout the season. The inner lines of the beds must be planted afterwards.

Pests Found in Garden, Greenhouse, and Stove (*H. C.*).—The creatures enclosed in the box are myriapods of the family *Julidae* (commonly called snake millepedes), and the particular species *Julus londinensis*. It very closely resembles the earth millepede (*J. terrestris*), the chief difference being in the first named having the apex of the tail rounded, whilst in the latter the pre-anal segment is pointed. It feeds on dead or decaying animal and vegetable matter commonly, and also on roots of many plants, especially the young and tender fleshy rootlets, and on root crops, such as Carrots, Parsnips, Potatoes, Beet, &c., and has been found feasting on Strawberries. For outdoor crops sprinklings of soot, a peck per rod, and nitrate of soda, 1 oz. per square yard, on the ground have been found useful, also dressings of quicklime. For clearing the pests out of greenhouses and hothouses there is no better plan than trapping. Pieces of Carrot, Mangold, or Parsnip, preferably partially decayed, or with holes in them, form excellent baits, inserting them just beneath the soil, or even on the surface, covering very lightly with light, partly decayed material, such as litter or moss, examining the baits every morning, and destroying the pests secreted in the hollows of the substances. This we have found the best means of riddance so far as greenhouses, hothouses, and out-houses are concerned, accompanied, of course, with thorough cleanliness. Outdoors we have found a dressing of quicklime useful, this hastening the decay of the organic matter by which they are mainly encouraged.

Begonia Gloire de Lorraine (*H. S.*).—Like others of the fibrous-rooted race of *Begonias*, and particularly those of such free-flowering tendencies, there is sometimes a difficulty in getting cuttings quite free from flower buds. No trouble, however, need be experienced if plants are healthy, and time is allowed for shoots to rise from the root stems, which may not be until late in the spring. When the flowering period is past, rest and dry the plants somewhat; then cut them down to within a few inches of the soil, and if shoots spring up having flower buds in them do not use these as cuttings, but wait for a later growth. The plants do not need any special treatment beyond keeping the soil slightly dryer before and after being cut down. There is a loss rather than gain in cutting them down early with the view of producing good cuttings, as early growth will most likely produce flower buds. When the shoots are about 2 inches in length they may be taken off with a slight heel, and inserted singly in small pots, or round the sides of a larger size. Loam, leaf mould, and sand in about equal parts will furnish a suitable rooting compost, which should be kept only sufficiently moist to keep the cuttings rigid. In a warm and close propagating frame they would soon emit roots, but a watchful eye must be kept on them to arrest damp in the leaves, to which all softwooded *Begonias* are liable. Once rooted give more air, and the best conditions and attention circumstances permit, and by the autumn well furnished and freely flowered plants ought to be the result.

Names of Plants.—We only undertake to name *species* of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*H. G.*).—1, *Odontoglossum grande*; 2 *Anthericum variegatum*; 3, *Woodwardia radicans*; 4, *Freesia refracta alba*. (*F. S. C.*).—1, *Cyperus natalensis*; 2, *Grevillea robusta*. (*L. H.*).—The inadvisability of not posting packages of specimens for naming on a Saturday, which means they must remain in the post over Sunday, has frequently been adverted to. Please bear this in mind when you send again, as all your specimens were quite dead. (*H. S. C. P.*).—1, *Prunus sinensis flore-pleno*; 2, *Staphylea colchica*; 3, *Boussingaultia basseloides*; 4, *Deutzia gracilis*; 5, *Crassula lactea*; 6, *Goodyera discolor*. (*Nemo*).—*Veltheimia viridiflora*. (*Idem*).—1, *Angræcum sesquipedale*; 2, *Phalænopsis grandiflora*.

THE DISTRICT ANALYST.

We live in the golden age—the age when a beneficent Government provides us with privileges and opportunities at our very door. (N.B.—This is not meant as a joke.) The district analyst is one of the outcomes of Government care. We do not wish to give Government all the credit for this step in the right direction, for it was only after constant effort on our part that the Bill touching fertilisers and feeding stuffs became law. But how many of us have been interested in this move? We have seen large posters referring to the matter on our notice boards for several years now. How many of us have stopped to read them? True, the type was small, and the matter looked uninteresting; but still that is no adequate reason for our negligence.

Possibly, if we thought at all, we considered the matter had no interest for us, and thus passed on one side. But here was the mistake. The Bill is framed for the benefit of all farmers, great and small; and, dare we add, it is the small man who should be the most benefited, if he only knew how to set about it. The larger transactions

of the 1000 acre farmer form his safeguard. A man of that standing deals only with large, well-known firms, whose word is their bond, and who would scorn to sell anything on false pretences.

Then again, even should a large order be placed in the hands of manufacturers of doubtful reputation, they would hesitate long before committing themselves, judging—and judging truly—that in case of any doubt the large farmer would not hesitate to avail himself of analytical aid, provided cheaply through his membership with the R.S.A. or other kindred society. We say again, it is to the small buyer that the Act should be of the most service. Presumably, he is a shrewd man, but not quite up to all the tricks and devices of unscrupulous dealers; he does not quite know the exact nature of the action of the tillages he buys; if the cake does not feed quickly he puts it down to the fact that his beasts are poor doers, or not so well bred as his richer neighbour's.

The agent was so pleasant and civil when he went to buy—ready to take off discount, and there was a capital glass of sherry in the corner cupboard, and there was much talk of the silver cups offered for the best root crops, and the good dinner and speeches at the nearest hotel. If the man knew the world as he knows his fields, he would see that all these cups and dinners and sherry wine had to be paid for by some one, and that it was out of his pocket and his equally simple neighbour's that the money came.

We fight shy of "bonus" goods, and of those shops that deal in free gifts, and yet it has taken us some years to see through the soft blandishments of the cheap cake and manure merchant. The first step towards effecting a better state of things is the knowledge of our need. As long as we think any sort of town garbage or blood mixture, or patent Turnip, Barley, or Potato manure is infallible, so long do we rejoice in our ignorance. Once we are convinced there is a better way, we shall not be far from the remedy. A clever farm foreman of our acquaintance—a man really who does his work well—was scandalised only the other day by his master's remarks on the subject of analysis. "Tak t' air to pierces and find out what it's mad' on! Lord Almighty niver meant us to kna; its runnin id fearce oi' Providence." Now it will be a lengthened labour to persuade that man that all compounds can be disintegrated and weighed to a minute fraction, and to the end of his life he would probably declare that the substance that made the greatest stink was the most perfect fertiliser.

We want in the rural districts some very elementary lessons on practical chemistry, and we hope and trust that the rising generation will not consider a man either fool or atheist who tries to know something of the internal structure of compounds in constant use on the farm. Now, we appeal to the listening ear and open mind. Why not protect yourself from fraudulent manufacturers, when you have the law on your side, and the method is so reasonable?

We begin with cake, and suppose, for argument's sake, we have not purchased our few tons from the best known makers. Their price list looked high, and in the confidence that "good wine needs no bush," they did not press for our custom, nor hold before our eyes glittering cups of silver, or the amber wine.

To the buyer cake is cake, and he supposes of necessity it must be pure. Has he ever looked at his invoice? Is the class of cake specified on it? If it be linseed cake have the matter in black and white. The Act compels the vendor to furnish a true description. A mixed cake must be sold as such; pure must mean pure. There must be no quibbling about commercially pure. A pure cake contains 95 per cent. of linseed, and no farmer who respects himself or the stomachs of his stock should be content with less.

The district analyst is always within reach. The fees may differ a trifle in various parts, but it is not large, and is often money well spent. Half-a-crown is about the figure, not a very killing matter. You doubt your cake just delivered does not correspond with the invoice description. The analysis must be made within ten days of receipt of invoice. The seller must have three days' notice of your intention that he or his representative may be present when samples are taken for analysis. Three samples are necessary—one retained by buyer, one by seller, and one sent to the analyst. That to the latter

must be accompanied by invoice or any other particulars bearing on the subject.

In the case of cake, where the purchase amounts to a ton, three must be selected—ground or crushed, and well mixed; any mouldy or unsuitable portions must be included in the sample, and from this bulk the three samples should be drawn, not less than 1 lb. in each lot. For feeding meals or grains, or manures in bags, three bags at least should be thoroughly mixed on a clean floor, and from that bulk the samples taken. In case the seller be not present, a competent witness must be there to see fair play, and to initial the bag or package containing his sample. All this may seem a bit tedious and red-tapey to the average farmer, but once let it be known that he only buys cakes, feeding stuffs, and manures on guaranteed analysis, and he may rest assured that for the future he gets the full value of his money. The ten days' practice may seem but a short time, but the Act is for the benefit of the vendor as well as the buyer, and we have seen cakes and feeding stuffs kept in such dog-holes, that there was no help for anything but quick deterioration, and it is not fair to saddle the seller with faults arising from the culpable purchaser's neglect.

WORK ON THE HOME FARM.

Showers of snow and 12° of frost on two successive nights remind us that it is yet but February and not April or May. We can do without the frost now, but in default of rain a little snow would be beneficial to help the Turnip land to harrow down better. Some of it has ploughed up rather knotty, and as it is very dry a nice soaking would make it fall like lime. Not much spring corn has yet been drilled, but March is considered early with us. We intend getting as much sown as possible during the next fortnight, as good a seed bed may not be available later on.

Wheats are stronger than ever, and during a long drive we saw many fields that we could hardly believe to be Wheat, so big were they, and we thought how much they would benefit from a good harrowing.

"What to sow?" is a difficult question to answer, but a decision must be come to. As to Barleys, Standwell and Goldthorpe did best last season, and there is a run on them for seed, but we do not like to desert our well-tried friend Chevalier, especially for later sowings; the other two varieties must be sown early if at all. We find Black Tartarian Oats difficult to beat. We are convinced they are still the best for yield, and they always command a fair price. The Garton White Oats that promised so well seem to have deteriorated very rapidly; last season a large number of grains did not properly develop, and they seem very liable to the attacks of insect pests. They are much finer in quality than previously, being thinner in the skin.

Until this frost we were getting on capitally with fallows. We had been able to burn a crop of twitch and get another one (we hope the last), worked to the top. Now we shall have to wait a little. Potatoes are a very slow trade at present, and few are being sent off; the markets are full of foreign, which, though of poor quality, fill up a gap. This frost may check arrivals and harden prices again.

We are preparing land for again planting, and shall commence ridging immediately, weather permitting. The sets are sprouting in the pies, and they would be better placed in the ground to be getting root-hold before the time comes for the top to make its appearance above ground. We are sowing kaimit now and harrowing it in before the ridging process, it will thus become well mixed with the soil.

20th.—Dull, with frequent rain in morning; intervals of bright sun in afternoon.

21st.—Fog till about 11 A.M.; then fair, with gleams of sun between 2 and 3 P.M.

22nd.—A sprinkle of fine snow between 7 and 8 A.M.; generally sunny from 10.30 A.M.

23rd.—Bright sun from 9.30 A.M. to 3.30 P.M., but slight showers at 4 P.M. and 10.30 P.M.

24th.—Generally bright and sunny, but occasional cloud.

25th.—Generally sunny, but overcast in evening.

26th.—Rain from midnight to 2 A.M.; brilliant day and night.

Weather still very dry, and colder than any other week this year.—G. J. SYMONS.

**FINEST SELECTED STRAINS
OF TESTED GROWTH**

BARR'S CHOICE FLOWER SEEDS.

A FEW SPECIALITIES.

ANTIRRHINUM, BARR'S QUEEN OF THE NORTH, snowy white, fine habit. Per packet, 6d. and 1/-.
AQUILEGIA, BARR'S LONG-SPURRED, extra selected. Per packet, 2/6.
ASTER, "PEONY PERFECTION," carefully selected; a beautiful mixture. Per packet, 1/- and 2/6.
BALSAM, BARR'S CRITERION MIXED. Per pkt., 1/6 & 2/6.
CELOSIA PLUMOSA, MIXED, a beautiful strain of this graceful annual. Per packet, 6d. and 1/-.
CINERARIA, BARR'S PRIZE. Per packet, 2/6 and 3/6.
COCKSCOMB, BARR'S EXHIBITION. Per pkt., 1/- & 1/6.
COREOPSIS GRANDIFLORA, BARR'S SELECTED STRAIN. Per packet, 1/-.
DELPHINIUM, BARR'S MAGNIFICENT "LONG DITTON" STRAIN. Per packet, 1/6 and 2/6.
TREE LUPINS, BARR'S FINE STRAIN. Per packet, 1/-.
PETUNIA, BARR'S SUPERB GIANT. Per pkt., 2/6 & 3/6.
POLYANTHUS, BARR'S HIGHLY COLOURED. Per pkt., 2/6.
PRIMROSE, BARR'S HIGHLY COLOURED. Per packet, 2/6.
PRIMULA, BARR'S "COVENT GARDEN" CHOICEST STRAIN. Per packet, 1/6 and 2/6.
STOCKS, BARR'S TEN-WEEK CHOICE DWARF STRAIN, in mixture. Per packet, 1/- and 2/6.
SWEET PEAS, BARR'S CHOICE MIXTURE of Newest and Finest Sorts. Per packet, 1/- and 1/6.
BARR'S SEED GUIDE (free), contains a Descriptive List of the best Vegetables and most beautiful Flowers.

SPRING.

WITH all the charms incident to the season Spring sometimes has an unkind welcome. Winter yields not the sceptre without a struggle, and many are the combats between the two. There are advances and retreats on both sides; days of sun and soft rains, days of gloom or snow-showers; nights of mildness and calm, and nights of frost or storm. Still, inch by inch Winter has to yield, and all the time the signs of the victory of the younger season are evident, for

"Through wood and stream, and field and hill and ocean, A quickening life from the earth's heart has burst."

The very name of Spring brings us a message of gladness and of hope. No other season has this power in so great a degree. In summer we know that the year is speeding fast and that the shorter days are not far off. In autumn, though we are reaping the harvest of the toil of the past, we know that winter is at hand to despoil us of our store; but in spring we are in our youthful days again, and the garden's year is before us to enjoy.

The earth is throbbing with life, soon to assert its power in spite of icy winds. These tiny seeds, the germs in some of which one can scarce discover, must soon feel its impulses, and die only to live anew in a higher creation. Think of all that Spring means—of its work, its beauty, and its significance—and then perhaps you will have to confess the pen too feeble to adequately portray them.

Wherever we go we see the beauties of the time. In the woods the trees bud forth into delicately tinted leaves, and the ground below sparkles with Nature's floral gems. The fields and meadows assume their most verdant garb, and by the streams plants push up their succulent stems and leaves of many forms and shades. Chaucer's Daisy, Wordsworth's Celandine, Herrick's Primrose, with many other flowers, are astir and welcome us by the wayside or the dell. The world beyond our gardens is, in truth, very beautiful, and he who could tell its charms would be gifted indeed.

But our tale is more of the garden than of the fields, and woods, and dells. It ought to be, as it

were, the quintessence of the graces and charms of the floral world in spring. Golden or white and yellow Daffodils nod gracefully to each other; Crocuses spread open their lustrous flowers to the call of the sun; Violets delight us with their delicious fragrance even more than by their simple beauty; Forget-me-nots look up with sparkling eyes to the heavens above, whence their colouring came; queer, quaint Snake's Head Lilies from quivering stems sway to and fro their chequered bells, and stately Crown Imperials look disdainfully down upon them, as if denying that they may claim to be cadets of their noble race. Blue Scillas and the Glory of the Snow are bright companions for the Grape Hyacinth, with its clusters of blue and pearly bead-like flowers. Like well-drilled regiments stand in gardens where they are grown the prim and waxy Hyacinths, and Tulips in brilliant array salute us as the winds of spring come past. Gay Anemones, golden Alyssum, white Arabis, purple Aubrietias, powdered Auriculas, sweet Primroses, showy Polyanthuscs, and a host of other flowers, are called into birth by the sweet springtime.

What can we say of the attractiveness of orchards and shrubberies? Apples, Pears, Cherries, and Plums give us clouds of white or rosy tinted flowers, and hopes of fruit in later days; add to these the wealth of flowering trees and shrubs in wonderful variety, of stature, form, and colour, then will it be admitted that they impart an aspect all their own to the diversified beauty of spring. So far we have dwelt upon the more attractive aspects of the season, but we cannot end thus. We must not be mere lotos-eaters, doing naught but enjoy the pleasures of the time among the blossoms. There is work to be done, work which brings with it much pleasure, as we can see from the many who follow gardening not for gain of money, but for love. There is pleasure in turning over the fresh soil; in making the garden trim and neat; there is pleasure in sowing even the commonest seeds, for we can think the while of their future growth. What though they only produce the homely Onion, the curled Parsley, or the other products which minister to our creature wants? All life is not play. "The trivial round, the common task," if well performed, bring enjoyment in their train. Yet we cannot but think 'mid all our pleasure of the overburdened, who, in undermanned gardens, have to toil from daylight until dark. Dig! dig! dig! is the refrain which is so often in their minds. Think, we pray, ye who have such gardens, and see that to none of your employes will the happy time of spring become a crushing weight—a season to be dreaded—because of the excessive toil it brings. It is such to many.

And, ere we close, let it be said that much of the garden's year depends upon the spring. If the tide be taken at the flood with timely forethought it will be well for all concerned. Plans thought or carried out too late result in eyesores or failures. Wise prevision will prevent this, and will see that little is left unprovided for. Still, with all, disappointments await. Blossoms may be blighted, flowers and fruit may fail, vegetables may be unsatisfactory. These things, much as we dislike them, generally bring their lesson.

As has been said, "To the brave man good and evil fortune are as his right hand and his left; he makes use of both." Misfortune never comes empty handed, though the gift be hard to find. We began with joy; we end with a homily. In life these are interwoven. Spring is full of joy yet full of instruction. He will indeed be wise and happy who can read its lessons aright.

THE PROSPECTS OF GARDENERS.

FORTUNATE it is for the prosperity of this island that the inherent love of gardening is as strong in humanity to-day as when vegetation flourished in the "Fair Garden of Eden." Throughout the land there is no lack of candidates to fill the many situations which become vacant in the horticultural world; indeed, in regard to private gardening, the sad side of the picture is that so many good men are unable to obtain such positions as they are undoubtedly well qualified to fill. The death of an employer, and the serious reduction of an establishment, throw out of employment many gardeners who in reality are in their prime, yet because they happen to be on the "wrong side of forty," are not regarded with favour when they apply for a vacant post. Considering how comparatively late in life the average gardener—who has been trained in good establishments—succeeds in obtaining a good head place, his best opportunities usually occur during the limited period of ten years. Things are not likely to improve in this direction, because we are passing through a period of evolution in gardening, which has been brought about by economic laws. There is, however, in my mind nothing to be alarmed at, we have only to accept things as they stand, and shape our course accordingly. Among gardeners, as among all other bodies, there are many grades. Some have been induced to take up the work because they possessed a thorough love

for it, and have been satisfied with securing a fairly comfortable place where the staff has never been a large one. For such men there are many openings during the worst times.

There seems to be a great future ahead, for the well-to-do middle class and the number of successful business men increases. These, at the present time, keep up their gardens in good style, and pay such wages to those employed in the gardens, that many a garden chief who serves a duke or an earl may well envy his contemporary in the smaller or less high-sounding establishment. For men with good cultural ability, who neither lack energy nor brains, there is a good field open yet; but for those who have false ideas of refinement, who think more of a name in regard to an employer than of substantial advantages in the struggle for existence at the present time, they are, I fear, likely to be "handled roughly." Let me try and make my meaning quite clear, and also to adduce the condition of affairs which lured many on to the fatal quicksands.

A large proportion of gardeners are drawn from rural districts, in which mansions and castles, surrounded by extensive gardens, are situated. The young men from the bothies are regarded with envy by the village lads, and the great ambition of many of these is to get into the hall or castle gardens, because it seems to offer the one opportunity to rise in life which the village affords. By persistent application, or perhaps the influence of a friend, they in time succeed in entering the—to them—charmed domain. Their ambition is not great, and in time they succeed in reaching their goal, in the shape of a place with two or three hands under them. In this they are contented and happy, and seem to have found their especial sphere in life. Now let us consider the case of another type of village lad—one brought up in fairly good circumstances, with an inherent love of gardening. Such see and envy the head gardener of some neighbouring lord, who happens to be fortunately situated in serving a wealthy, generous, and garden-loving employer. The youth takes the position of such a gardener as his model, begins his gardening career with a determination to reach a similar position himself, and makes up his mind that with that and nothing less he will be satisfied. He toils assiduously for years, makes work and study his chief considerations, and passes on steadily from one stage to another, till he has been foreman in some princely establishment for some years. Here he has given his chief every satisfaction, and the time comes to seek a responsible position for himself. His chief does everything in his power for the faithful worker, but he cannot make places, and so the weary years roll on, till, through being tired of what seems endless waiting, a position is at last accepted to take charge of some fine old garden, which "has been" well kept in its day, but through adverse circumstances dwindled down, till it is only a ghost of its former self. The expenditure in labour and material is cut down to the lowest possible point, yet the requirements do not materially decrease. The result is that a few years of this attempting to "make bricks without straw" ends in disgust with the whole business.

Still some are compelled to plod on because they lack the ability to adapt themselves to altered circumstances and strike out in a new direction. Fortunately, however, there are many bright examples who have shown what can be done, for by their foresight they have realised that gardening is not "decaying," but only changing in form; they have noted there is a greater demand than ever for good garden produce, that flowers, plants, and fruit are required in enormous quantities by the rising masses; that fact being grasped, their energy and pluck has induced them to strike out boldly; difficulties were of course met, but fought with determination and overcome. Some of these men to-day, instead of holding shaky positions on trust in their old age, have prosperous businesses of their own, in the conduct of which they can end their days in content, and bequests to their children. There have been failures of course in this direction, but any man at middle age ought to be able to judge of his capabilities, and act accordingly. Often the failure has been brought about by flying to the neighbourhood of London, where the market is often overstocked, while good openings occur in other parts to work up a local trade.

And now for a few words to the young who have settled to embark in some form of horticulture; to them I say, Do not be led away by the glamour of appearances connected with many private gardens. If you have energy and brains, get into one of the finest schools of horticulture in this country or the world—viz., a great market establishment. The appearance of such is often not so inviting as a private one, but the work is child's play compared with the drudgery that prevails in some private places. The wages given are better throughout, and to a good worker, not inclined to be a spendthrift, the prospects in after life are infinitely better, for the time has come when those who provide for the wants of the general public rather than for a special class, will reap the surest reward. The matter may be put in a nutshell in this way. In private gardens bricks are often expected without straw being supplied to make them with; in market establishments the necessary straw is freely provided, but the bricks—in the shape of good results—are not only expected, but also demanded.—ONWARD.

AN HOUR AT ROSEFIELD.

It was on one of the foggiest mornings in January that an attempt was made to reach Sevenoaks in time to insure a couple of hours amongst Mr. De Barri Crawshay's Orchids at Rosefield. However, fate in the shape of the South-Eastern Railway Company decreed otherwise, and the train was just one hour late. One hour, therefore, was at disposal, but short as it was it proved to be sufficient for much of interest to be seen both of plants in and out of bloom as well as hundreds of dried flowers.

Fortunately, Mr. Crawshay is a man of action, and before I had well got inside the door my overcoat and hat were off, and just fifteen seconds later we were busy amongst the dried blooms. These are pinned on trays, which fit in cases in the library, and from them the life history of many an *Odontoglossum crispum* can be read. Here will be the first flower after importation, there the second, and yonder the third, and so admirably have they been preserved that the development of the blotches and markings on some, with the improvement of sepals, petals, and lip of others, can be seen at a glance. Then there were the *Lælias*; but no time was to spare here, so the trays were returned and we made for the houses. This system of preserving specimens is a splendid one, and if the fates (and the S.E.R.) are propitious in the future it is the intention of the writer to devote more attention to them.

It is no doubt well known to the Orchid growing section of Journal readers that at Rosefield *Odontoglossum crispum* and *Lælias* are the specialties, and frequenters of the Drill Hall know well with what success they are grown. Purchases are constantly being made, and it is but reasonable to add that plants are with equal constancy being turned out as not coming up to the requisite standard. Mr. Crawshay has his ideals, and at these he aims with unswerving determination. A variety has to be well nigh perfect to be kept, and must be in some respects superior to any existing ere it receives a name. On this point the grower holds very emphatic views, with which we are in entire accord. He is of the opinion that no variety should be named unless it is either decidedly superior to, or perfectly distinct from, any in cultivation. In this he is quite right, for there are hundreds of Orchids and other plants named every year that ought never to have been so treated. At the same time, it is more than probable that the practice will be persisted in.

To name particularly all the best of the Rosefield crispums would occupy too much space; but if the list of certificated Orchids of the Royal Horticultural Society be turned to, many will be found, and this list alone testifies to the excellence of the stock. One thing is certain, which is, that Mr. Crawshay seldom brings plants to the Drill Hall without taking back with him either an award of merit or a first-class certificate. This will show that his ideal is a good one, and quite in consonance with the opinions of the Orchid experts, who are sometimes, and rightly, very hard to please. The condition of all the plants is very satisfactory; they are clean, bright, and look to be in splendid health. Some are young, and others have grown old in years, all stages being represented. There are tiny seedlings, and there is the first plant of *Odontoglossum crispum* that Mr. Crawshay ever had, and it is superfluous to add this is not for sale.

The *Lælias* were making a braver show than the *Odontoglossums* when this visit was paid, for several forms of aneeps were in flower. Here again it was evident that only the best are wanted, and several of the best varieties in cultivation are there comprised. A week prior to the journey a plant of *Lælia Amesiana*, Crawshay's variety, had been sent to the Drill Hall and had received an award of merit from the Committee. This is represented in the woodcut (fig. 32), and is one of the most beautiful varieties that has been seen. The petals are broad and of great substance, the colour at the base being white, which gradually deepens until at the tips it is bright rosy red. The lip, which is rather small, is a peculiarly deep velvety crimson. This is only one of many splendid Orchids that have emanated from the Rosefield collection, and it cannot for a moment be doubted that the owner will continue to send to the Drill Hall some of the handsomest members of these two families.

There are other kinds of Orchids grown, but to these the chief attention is given. By thus specialising Mr. Crawshay can grow both

to an exceptionally high degree of perfection, and attain the best results. Curious to relate, not a single *Cypripedium* is grown. Seedling raising is followed up closely, and interesting results may be anticipated from some of the crosses that have been made from time to time. The particular mention of these must, with the others, be postponed until a second visit has been made, and more space is at command.—H.

STOCKS FOR APPLES.

GRAFTING time has arrived, and amongst those who have to devote some portion of their labour to this operation attention is necessarily directed to the stocks most suitable for the purpose. The question, Which is the best stock for Apples? has often been discussed, opinions varying greatly with the experience of different observers, but decisions must be influenced to a great extent by the objects or requirements of the cultivator. It is agreed in a general way that the Crab or free stock is the best for standard and orchard trees, while a Paradise or

FIG. 32.—LÆLIA AMESIANA, CRAWSHAY'S VARIETY.

dwarfing stock is the most suited for bush or pyramid trees—i.e., garden trees. This is subject to some modification, for there are certain varieties which appear to prefer the Crab stock whatever be the form of tree grown, while others display a similar preference for the Paradise, just as we find with Pears on the Quince and Pear stocks, local conditions of either soil or climate in most instances exerting a material influence.

There must be some degree of similarity in growth between the stock and the scion, or short-lived and unsatisfactory trees will result. Thus a very vigorous variety is sometimes worked on a dwarfing stock with the object of reducing its growth and promoting earlier fruitfulness. This end may sometimes be attained, but it more commonly happens that the growth of the scion stem is out of all proportion to the stock stem, with a huge swollen juncture as the result, rendering it impossible for a tree to remain satisfactory so long as it would do with a better union. A heavy crop of fruit or severe injury to the foliage by insect attacks will often weaken such a tree to so great an extent that it remains stunted for the remainder of its life. I have had strong growing varieties on a Paradise stock five or six years old, of which the stem immediately above the juncture was nearly double the diameter of the stock, an obviously unsatisfactory state of affairs.

In the same way some of the weaker varieties of Apples are not improved by being placed on a Crab stock, as might be imagined; in the first place, it is often difficult to induce a weak variety to "take,"

either as a graft or bud, on a strong Crab stock; and even if this be accomplished the growth is frequently rendered irregular and unfruitful, being "forced," as it were, out of its natural habit. Varieties of medium growth more readily adapt themselves to either stock, and give the best results in healthy growth and good fruit. The extremes require careful study, and must be allotted stocks more proportionate to their growth.

The essential difference between the Crab and Paradise stocks is that one is a seedling and the other a layer, or plant derived from its parent by vegetative increase. In other respects, though the terms Crab and Paradise are employed as if they indicated a definite and fixed form, they are very misleading, and it is no doubt largely due to this that such varied opinions are formed as to the behaviour of particular varieties on the two stocks. The fact is, there is a great range of variation in the Crab stocks employed, as there also is in the Paradise stocks, and I have known Crabs employed for the same variety of Apple between which there was a greater difference in roots and growth than between some Crabs and some Paradise stocks.

I have had many thousands of seedling Crabs through my hands, and have found the growth of those from the same sowing differ enormously at all stages up to the budding or grafting period. For example, seedling Crabs of the same age when first transplanted will often range from 1 foot to 6 feet in height, and from half-inch to 2 inches in circumference, while the roots will vary from the strong downward fibreless growths, characterising the Crab, to spreading fibrous roots barely distinguishable from a Paradise. When scions or buds of the same variety are placed upon such varied stocks the results are frequently varied proportionately, and when the plants are distributed we have trees both on the Crab stock giving very different records in crop and growth, though the original cause of divergence is not then traceable.

A greater uniformity is obtained with Paradise stocks, because in all the best nurseries there is some special form which has found favour, and these are increased by layers, which give much more regularity and evenness in size and strength. But there are many so-called Paradise stocks in cultivation, and leaving out of consideration altogether the extremely dwarfing French types, which are discarded now in many places for general business purposes, if those from the leading nurseries are compared closely they will be found to differ materially amongst themselves. I have one that admirably suits a certain variety of Apple, and yet if the roots only were seen it might be taken to be a Crab; the only apparent difference being that the roots have a more horizontal direction, they are strong, hard, and fibreless, precisely like those of a hedgerow Crab.

In selecting young stocks for grafting it is the practice to employ those with clean, freely grown stems, and this is undoubtedly necessary; but in my opinion we begin at the wrong end, they should be selected by their roots in the first place. This applies more particularly to seedlings used for stocks, whether Crabs or Apples. Strong roots with a vigorous growth give us the "free" stock type—*i.e.*, abundant growth, later fruiting, and longer life. Plentiful fibrous roots, with moderate growth, afford us the dwarfing early fruiting Paradise type.

In a general way all seedlings possess more vigour as stocks than those raised from layers, and in some parts of England, especially in the cider districts, large numbers of seedlings are raised for this purpose; but it is done in an indiscriminate manner, and the results are varied or unsatisfactory in consequence. If seedlings are raised, not merely from one variety, but from the fruit of the same tree, considerable divergences will be observed; but there is a certain general character running through them which adapts them for use as stocks, though their produce as seedlings would be various. Two of the best varieties for yielding a proportion of seedlings of the Paradise type are Cox's Orange and King of the Pippins, and the fruit of these is too valuable to be devoted to seed-raising as a rule. But I have obtained a larger proportion of fibrous-rooted seedlings from these than from any others I have tried.

With regard to the form of trees, it may be said that personally I am strongly in favour of bush or pyramid Apple trees, either on the free or dwarfing stocks, because they have so many points in their favour; but experience has proved that where an intermediate form of the Crab stock can be chosen, it will give in the case of some varieties, of which Lane's Prince Albert is the best example that occurs to me on the moment, a stronger habit and better tree than the ordinary Paradise. For many weak and medium growers I have found nothing better than the Broad-leaved Paradise.

Budding is so generally practised now, that by some grafting is regarded as out of date; but when dealing with strong or old stocks the latter method is far before budding, as it will give a greater proportion of successes, and where there is a good root below and a clean union is formed, four to six strong buds starting in the season, it will be found at pruning time that the foundation of a well-proportioned tree is obtained, which would take at least another year to secure from buds.—R. R.

THE SCIENCE AND PRACTICE OF FORMING FRUIT TREES.

ABOUT the middle of February in forward seasons and warm localities the buds of fruit trees usually commence swelling; by the beginning of March, or from then to the end of the month, according to season and location, recently planted young bush and standard trees will have pushed the top buds more or less, and then, perhaps, be in the best condition for pruning in order to induce the production of vigorous growths from the pruning buds. I say, perhaps guardedly, for it would not be difficult to produce evidence of early autumn pruning tending to give satisfactory results in the following season, as the more or less activity of the juices during the autumn and mild weather during the winter are concentrated on the pruning buds—that is, they plump and make ready for a start in the early spring, whilst the roots callus at the clean cut parts, and the fibres form adventitious root-cells, or what may not inaptly be termed root-buds, for development into soil branches.

In most cases, however, early autumn planting is seldom practised, so that the physiological conditions foreshadowed do not commonly arise in the case of ordinarily planted young bushes and standards. The general practice is to wait until all the leaves are down, which implies planting in late autumn, during mild weather in winter and early in spring, or whilst the trees are quite dormant, more as a matter of convenience than involving any question of principle. Nevertheless, I am satisfied that the most suitable time to plant trees is in the early autumn, when most of the leaves have fallen, if not all, and the next best time early spring, when the buds begin to quicken.

By the first we secure to the tree the advantages of the descending current or transference of the plastic materials, and these secure a callus to wounds and even adventitious roots from fibres, and this without top growth. By the second the juices are then at such state of tension, and the conditions so favourable to the transference and diffusion of the stored plastic substances, that the growth is pushed upwards and roots downwards with such force and reciprocity as to become surely and quickly re-established. This applies alike to evergreen as well as to deciduous trees.

The November or early winter-planted tree has the advantage, as if the weather prove mild it will have the soil settled about the roots by rains, and thus in touch with the supplies of moisture and nutrition which prepare to grow afresh at the present season, as shown in the illustration (fig. 33, A), the cleanly cut roots callusing (*a*), and the terminal buds commencing to swell (*b*) all over the tree. These we get by this time (March), earlier or later, and then the question of pruning arises, if it has not already been done before the buds have commenced swelling. Under ordinary circumstances no harm is done by leaving the shoots unshortened until now, for if the greener parts of the shoots part with moisture on dry days they take it in during damp or wet periods, so that if there be any elaboration of matter, as there certainly is diffusion and transference of plastic materials, the balance of benefit is found by retaining the shoots intact. Besides, if the winter be severe, and the summer previous has been cold, the wood may not be ripe, hence pruning at planting means wounds liable to injury from frost in greater degree from the more moisture resting on them than there would be if the growths were not shortened; so that in the latter case the soft wood suffers instead of the more ripened, whilst any keen frosts in the early spring act on young wood instead of the basal parts of the shoots. Rose growers practise this as a safeguard against spring frosts, and it is quite sound in theory, and satisfactory in practice.

The tree portrayed (fig. 33, A) is a fair sample of a one-year-pruned bush. It has been headed as a maiden at (*c*), giving rise to several shoots—four strong ones (*d*), and six of less vigour (*e*), with a spur (*f*). It may be an Apple tree or a Gooseberry bush. The principle is the same, for it is a bush we want, and the only difference between that and a standard is in the stem. For the bush we cut the maiden tree at a foot from the ground, or at most 18 inches, to get, in the case of the Apple, the branches well above the ground so that the sun can reach the soil, the branches not interfering with feeding and cultural operations, nor the fruit splashed by rains. For the standard we train up the maiden to a height of 3 feet for a half, and to 6 feet for a full standard, and at one or other of those points cut off its head; thus there is no difference between the head of the bush and that of the standard. The bush may be regarded as the tree of the future, the plantation instead of orchard, as all its requirements can be attended to from the ground without aids of a time-wasting character. There are several modes of treating such tree.

1, THE RECIPROCITY OF SERVICES METHOD.—Leave the weak and short (*e, f*), and shorten the long and strong shoots (*d*). This shortening is imperative for shaping the tree, as the space must be utilised to give satisfactory returns by having branches for fruit production covering it equally, and with the same admitting light and air to pass freely into the head; therefore they must not be too close, especially in origination, this being a very common error, and the lower part of the tree ultimately worse than worthless from the overcrowding of limbs, and for a time of spurs.

To obtain free growth the strong shoots must be shortened about two-thirds of their length, or to *g*, making at least level with the short and weak shoots. In consequence of the shortening we get at least two vigorous growths from each, as shown in part outline, and smaller ones towards the basal parts. Thus there is no check to the root action, or rather no congestion of sap, for the short and weak shoots have growths equally forward with those cut away; therefore the reciprocity of action between roots and branches remains intact, and as the strong shoots have larger sap vessels, the flow is so full and strong into the buds left that the upper ones start vigorously, and soon draw the nourishment away from the weaker, the leaves being larger and the shoots altogether in the ascendant.

The cut in pruning is an important consideration. If the tree be of erect habit it will always retain the characteristic, but it may be made to grow somewhat outwards by pruning to an outside bud (*B, h*), while a tree of spreading growth can be made to grow inwards or more upright by pruning to an inside bud (*i*). In the case of a tree of pendant habit (*C*) pruning to an upside bud (*j*) induces growth upward, and shortening to an underside bud (*k*) tends still farther to promote the pendant habit

FIG. 33.—PRUNING RECENTLY PLANTED YOUNG FRUIT TREES.

References:—*A*, shorten the long and strong, and leave the short and weak shoots: *a*, roots callused; *b*, buds started into growth; *c*, point of heading maiden tree; *d*, long and strong shoots; *e*, short and weak shoots; *f*, spur; *g*, point of cutting back strong and long shoots. *B*, upright shoot: *h*, pruned to an outside bud; *i*, shortened to inside bud. *C*, semi-pendant shoot: *j*, pruned to upside bud; *k*, shortened to underside bud. *D*, roots: *l*, clean cut callused; *m*, young rootlets; *n*, young fibrils.

of growth. These small matters must have attention from the pruner, as they have an important bearing on the ultimate fashion and utility of the bush or tree.

By pruning when the uppermost buds are pushed or even have grown somewhat, and confining this to the strong growths, the young shoots on the part unpruned develop their leaves, and the roots then, if early planting has been practised, will also be moving (*D*), the clean cut roots (*l*) having callused and put forth rootlets (*m*), while the fibrous roots have also made some healthy fibrils (*n*). These keep in touch with the leaves on the unpruned shoots and give a fibrous formation, whilst later the strong shoots come on the pruned, and then the roots spread wider and deeper, being more or less strong in accordance with the growths. The tree thus has secured to it both a fibrous and extended root formation.

The practical point at present is to shorten the long shoots of recently planted trees with necessarily shortened roots, such as that represented. Thousands of such trees have been ruined by leaving the young branches intact. It may be said, "They can be cut back the second year." Yes; but as a matter of fact not one in a hundred is then cut back, and that is where the danger lies. Safety rests in attending to the matter now for laying a good foundation for future thrifty trees. The small shoots (*e*, tree *A*, fig. 33) are to be removed when growths are freely extending from *g*, as foreshadowed by the dotted lines.—G. ABBEY.

(To be continued.)

— WEATHER IN LONDON.—Though we have had frost, snow, and hail since our last issue went to the press, we have had no real winter. The snow that fell on Thursday, Friday, and Monday did not remain more than a few moments. There have been sharp frosts on two or three mornings, and clear cold days. Sunday was particularly bright and invigorating, but since then cold easterly winds have prevailed. Throughout the whole of Tuesday the wind was bitterly cold, but during the night it became milder. On Wednesday it was clear and fresh.

— WEATHER IN THE NORTH.—Dry seasonable weather has marked the first eight days of March. The days have generally been clear in the former part with duller afternoons. On every morning but that of the 6th frost has been recorded, increasing from 2° on the 1st to 9° on Tuesday morning, when the rime was very dense and the hills retain their covering of snow.—B. D., *S. Perthshire*.

— FLORELEGIUM HAARLEMENSE.—Fascicle 5 of this work is before us, and the plates well maintain the promise of the earlier numbers. It is to be hoped the promoters are receiving the support they deserve for the excellent manner in which they are conducting their work. The part before us contains Hyacinth Hadyn, Tulips Duchesse de Parme, Thomas Moore and Ophir d'Or, with Nareissi telamonius plenus, incomparabilis albus plenus, and incomparabilis plenus sulphureus. Each plate is accompanied by explanatory letterpress. We may again mention that the publisher is De Erven Loosjes, Haarlem, Holland.

— ROYAL CALEDONIAN HORTICULTURAL SOCIETY.—The prize list and rules of the two exhibitions that are to be held under the auspices of the above Society are now before us, and the prizes should be good enough and the rules simple enough to insure two excellent displays. Both will be held in the Waverley Market, the spring show on April 6th and 7th, and the autumn one on September 14th and 15th. The latter is the more important, and comprises 263 classes with a total of £366 in prize money. The Edinburgh display of fruit is almost invariably an excellent one, and this schedule gives particulars of 117 classes all devoted to fruit. Schedules and all particulars may be had from Mr. N. Bryson, 18, Waverley Market, Edinburgh.

— NATIONAL AMATEUR GARDENERS' ASSOCIATION (LIVERPOOL BRANCH).—The first meeting of the season was held in the Common Hall, Hackins Hey, Liverpool; the newly elected President, J. H. Drake, Esq., presiding over a large attendance of members. The Chairman gave a short address, chiefly for the encouragement of those members who have not as yet become exhibitors, and no doubt his remarks will bear good fruit, for there is need of more rivalry at the exhibition table. An interesting display of spring bulbs was made; Mr. J. M. Smyth winning with two miscellaneous exhibits, Mr. Rees with Hyacinths and Azaleas, Mr. Cangle with Calla blooms, and Mr. Drake with an Orchid for a special prize. The President has kindly offered a special prize of 5s. at each of the meetings, whilst other gentlemen have given excellent special awards. An attractive syllabus has been arranged for the ensuing season. It is intended to hold a social evening at the end of the month.—R. P. R.

— ISLE OF WIGHT.—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on Saturday. Dr. J. Groves, B.A., J.P., presided over a large meeting present to hear a paper read by Mr. J. H. Perkin, The Gardens, Los Altos, Sandown, on "The Cultivation of Asparagus." Mr. Perkin, unfortunately, could not be present, and the paper was read by the Chairman. An interesting and profitable discussion ensued. Mr. R. Parsons received the Association certificate for cultural merit for a collection of Cyclamens. A vote of condolence was passed with Captain Eveleigh, an honorary member of the Association, in the loss of Mrs. Eveleigh. The questions as to forms of certificates for the forthcoming Island shows and the printing of the monthly proceedings for circulation amongst the members were, after some discussion, deferred to another meeting. It was decided that the April meeting should be held at Shanklin, and take the form of an exhibition of spring flowers. The arrangement of excursions for the forthcoming season were left with the Secretary. At the close of a most pleasant and instructive meeting twelve new members were elected, which brings the total to 250.—S. H.

— COMMUNICATIONS.—In consequence mainly of the considerable amount of space—though not, we think, too much—required by the description of Hatfield, the publication of several interesting communications and illustrations has had to be unavoidably postponed, but the contributors are equally thanked for their co-operation, whether their productions are inserted in the present issue or deferred.

— A VISITOR to Folkestone writes:—"There are Roses in bloom in some of the gardens here, and the new leaves of the Euonymus are almost as bright a gold as the Gorse on the banks. In a sheltered cottage garden down in the hollow, near Sandgate, there are Pansies in full bloom, as well as Polyanthus, Primulas, Daffodils, Primroses, and Bachelors' Buttons. The flower-girls are selling Mignonette, Stocks and Wall-flowers, grown at Sandwich, and of a delicious sweetness known only to home-grown flowers."

— A CURIOUS CASE OF PEAR FRUCTIFICATION.—I have a Jargonelle Pear about seven years old, on a west wall, and in robust health. By some means, seemingly about three years since, the bark got removed all around for the space of an inch or so a short distance from the main stem of one of the largest branches. For several years fruit has been pretty evenly distributed over the whole tree, but this year there are more than twenty whorls of fruit buds on the branch detached by the cutting of the bark from the main stem, and not a fruit bud on any other branch. How is this accounted for? There is no appearance of sap circulation, except it goes through the seemingly dry hard wood, where the bark was removed.—W. J. MURPHY, *Clonmel*.

— FEBRUARY WEATHER AT DRIFFIELD.—Mean temperature at 9 A.M. (corrected), 38.12°. Wet bulb, 36.39°. Mean maximum, 44.5°; mean minimum, 33.75°. Highest, 55° on the 1st; lowest, 22.5° on the 21st. Mean of maxima and minima, 39.12°. Mean radiation temperature on the grass, 29.12°. Lowest, 19.5° on the 21st. Rainfall, 1.28 inch. Number of rainy days, eighteen. Greatest amount on one day, 0.28 inch on the 3rd.—W. E. LOVELL, *York Road, Driffield*.

— FEBRUARY WEATHER AT HODSOCK PRIORY.—Mean temperature of the month, 40.5°. Maximum in the screen, 58.1 on the 15th; minimum in the screen, 21.7 on the 25th. Minimum on the grass, 12.4° on the 25th. Number of frosts in the shade, nine; on the grass, twenty-two. Sunshine seventy-three hours, or 27 per cent. of the possible duration. Rainfall, 0.68 inch. Rain fell on twelve days; maximum fall, 0.22 inch on the 28th. Rainfall from January 1st, 1.13 inch; difference from average—2.33. Another mild and dry month, but with more frosts than in January.—J. MALLENDER.

— A WEATHER CONTRAST.—It is reported that on Saturday last the heaviest snowfall of the season was experienced in Scotland. In the central Highlands there was a continuous fall for several hours, and in some places snow lay to a depth of 8 inches. The Australian mail on Monday brought the following records of great heat. On December 30th, under severe shade conditions, 107.3° was registered at the Melbourne Observatory; and on January 11th a still higher record, 109.5° was reached. At Boort (Victoria) the shade register was 116°. We should prefer Scotland.

— WEATHER AT DOWLAIS.—The following is a summary of the weather here for the past month:—Rainfall, 3.49 inches, which fell on twenty-three days. Snow fell on four days. Maximum rainfall, 0.52 on the 5th. Mean maximum temperature, 42°; highest reading, 52° on the 14th; mean minimum, 29°; lowest reading, 17° on the 20th. Below freezing point on twenty occasions. The wind was in the W. and S.W. on sixteen days, and very variable on the other days. There were twelve sunless days. Very mild and open until the last twelve days of the month, during which the frost has been more severe, with at times brilliant sunshine in the daytime.—W. MABBOTT.

— THE WEATHER LAST MONTH.—February was much cooler than January, with sharp frost on the 21st, 22nd, and 23rd. The wind was in a westerly direction on twenty-four days. The total rainfall was 0.61 inch, which fell on thirteen days; and is 1.20 inch below the average for the month. The greatest daily fall was 0.11 inch, on the 17th and 25th. Barometer (corrected and reduced), highest reading 30.291 inches, on the 11th, at 9 P.M.; lowest 29.196 inches, on the 21st, at 9 A.M. Thermometers, highest in the shade 56°, on the 1st; lowest 20°, on the 21st. Mean of daily maxima, 45.82°; mean of daily minima, 33.21°. Mean temperature of the month, 39.50°; lowest on the grass, 13°, on the 21st; highest in the sun, 102°, on the 27th. Mean of earth temperature at 3 feet, 41.82°. Total sunshine, ninety-eight hours forty minutes, which is thirty-eight hours above the average. There were two sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

— ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the Society, to be held, by kind permission of the Council, at the Institution of Civil Engineers, on Wednesday, the 16th inst., at 7.30 P.M., a lecture will be given by Mr. Arthur W. Clayden, M.A., F.R.Met.Soc., on "Photographing Meteorological Phenomena," which will be illustrated by lantern slides.

— NATIVE GUANO.—Once more the Native Guano Company favours us with a book of testimonials, which cover about seventy pages, and come from all parts of England, Scotland, and Wales, with some from the Channel Islands. Each year a fresh list is compiled, and each year brings abundance of good material for the book. The testimonials refer variously to flowers, fruit, and vegetables of all kinds, and the guano thus appears to be admirably suited for everything.

— "A STRANGE THEORY."—This (page 189) is indeed strange as physiological connection in the issues involved seems absent. If plant sap ebbs and flows as suggested, it can only do so when not in its state of stagnation in which it is deemed to be during winter. We do not ordinarily prune Vines least of all, when the sap is moving, and discrimination between the ebb and flow of tides during the dormant state of the sap does not seem imposed by any logic.—H. H. R., *Forest Hill*.

— SOWING TOMATOES FOR OUTDOOR CULTURE.—The present is a suitable time to sow Tomato seed thinly in a pot or box to raise a stock of plants for outdoor planting. They are better raised now than earlier, inasmuch as the seed germinates quicker, and the seedlings grow more sturdily under the influence of increased light and natural heat. Keep them close to the glass in all stages, and in as little artificial heat as possible after becoming well established.—E. D. S.

— "CARNATION MANUAL."—The second edition of the "Carnation Manual," which is edited and issued by the National Carnation and Picotee Society (Southern section) at the price of 3s. 6d., is a book that should be very valuable to all lovers of these beautiful flowers. There is a preface by Messrs. Martin R. Smith and J. Douglas, introductory chapters by the Rev. F. D. Horner, as well as articles of various points in cultivation by some of the best known specialists. The book, which is neatly bound in red cloth, may be procured from Mr. T. E. Henwood, Auricula Villa, Hamilton Road, Reading, for the price named, plus about fourpence for postage.

— HESSLE GARDENERS' SOCIETY.—A meeting of the above Society was held in the Parish Hall on Tuesday, February 1st (Mr. Geo. Picker, Hesslewood, in the chair), when Mr. Geo. Wilson, gardener to Sir James Reckitt, Bart., Swanland Manor, Brough, a well-known exhibitor of groups, contributed an excellent paper on "Grouping for Effect; What to Imitate and What to Avoid." The essayist commenced by describing the first group that he saw exhibited, which he said reminded him of a thatched roof with a gradual slope. Among the things he tried to avoid was making a group similar to what he had seen elsewhere; attempting to make a pattern; taking too many plants to shows; and being late in getting a start and overcrowding. The only thing to imitate, in his opinion, was Nature, and in trying to do this as far as possible the essayist attributed his numerous successes. There was a large attendance of members present, and a good discussion followed. Votes of thanks to the essayist and Chairman terminated the meeting.—G. W. G.

— ECONOMIC RESOURCES OF THE WEST INDIES.—A special issue of the "Kew Bulletin" embodies Dr. Morris' views on the economic resources of the West Indies, and a more interesting work on the subject could hardly be wished. The author accompanied the Royal Commission to the West Indies in the early months of last year; but apart from this visit, his intimate knowledge of the Islands qualify him to undertake the task. Each Colony has been dealt with separately, and every point has been brought out with a clearness that is not always found in works of a similar nature. That the Commissioners appreciated the efforts of Dr. Morris is proved by the note below, which appears towards the conclusion of their report:—"We have had in the course of this report to refer frequently to the very interesting and valuable survey supplied by Dr. Morris of the agricultural resources and requirements of the Colonies visited by us, which forms Appendix A in this volume. Dr. Morris's presence with the Commission has been of great advantage to us; no adviser could have been assigned better qualified, both by general and local knowledge, to assist and inform us in regard to botanical and agricultural questions. The report which he has prepared bears witness to the closeness of his study of these questions, and the assiduity with which he has collaborated throughout the course of our inquiry to further the purposes of the Commission." The entire work may be procured from Kew for 1s. 6d.

Hatfield House, the Seat of the Marquis of Salisbury.

WHO has not heard of Hatfield? To the populations of the English speaking world, and to many millions besides who speak their own mother tongues, the name of Hatfield is known—not perhaps so much as a magnificent estate, but as the home of one of England's greatest statesmen, whose reputation will be handed down to the future by historians, even as the doings of his ancestors have been passed down to us. Look far back into the pages of history, and the family achievements in the political arena will be found in page after page, dynasty after dynasty, century after century, and when you reach the time of the maiden monarch you will find Sir William Cecil, afterwards Lord Treasurer Burleigh, one of the leading politicians of the time. To-day history is repeating itself, for the Marquis of Salisbury, a descendant from the Elizabethan Minister, occupies the highest position in Victoria's Parliament. The reigns of both these rulers have been beneficent, and in the glory of each reign is reflected the glory of the Cecils. It is not proposed, however, to trace the history of the family back from the year 1558 to 1898, at least only so far as it affects the subject of the present notes

history of gardening for nearly three centuries. It, doubtless, has had its vicissitudes, but these lend charm to the page and make the picture painted in the mind more beautiful still. So interesting is the history of Hatfield that we shall venture beyond the bounds of horticulture, but not so much so, it is hoped, as to make the recital uninviting to our readers.

As has been said, Hatfield came into the possession of the Cecils just after the death of good Queen Bess, but prior to that it was a place of note, and during the reign of this monarch it was a royal residence. For about seven hundred years Hatfield has been widely known, and a part of the old Palace, which, during the reign of Mary, was occupied by Elizabeth, who was practically a prisoner, still remains, and is shown in the photographic reproduction (fig. 34). The portion there depicted was the banqueting hall, which is now used as a stable, providing adequate accommodation for upwards of two dozen horses. The roof of this structure, which is comparatively lofty, has the appearance of being of oak, though one good authority states it to be of Spanish chestnut.

FIG. 34.—THE OLD PALACE AT HATFIELD.

—namely, Hatfield House, which came into possession of the family shortly after the accession of James I. to the throne. But let us pass for a moment from the historical features to those phases that come more within the social province.

To travellers by the G.N.R. Hatfield has become familiarised by the conservatory, of which a glimpse may be caught as the train speeds past on its journey north or south; indeed, to many going in the latter direction it is the signal that London will be reached in about twenty minutes, and therefore preparations must be made for detrainment. But few of those passing thousands have any conception of the magnificent house, the superb park, the ancient buildings, the relics of bygone ages which may be seen on every hand. To the one who is wholly interested in historical detail Hatfield would prove an almost inexhaustible storehouse, while the visitor who lives in the present will have his mind no less occupied in studying the several features of the house and park. In this connection one can re-echo the sentiment of Bishop Wilberforce, who said of Hatfield: "This is a place at once of historic interest and of present enjoyment." Truer words were never spoken than these, and none but a cultured mind could thus have summed up in a dozen words the description of a lordly estate. Arboriculturists would find here food for many a thought, while horticulturists could with little effort read in the estate a

In Saxon days the name was Hetfulle, and the estate belonged to the Saxon kings until it was given to the monastery of St. Etheldreda at Ely by Edgar. It became then a residence of the prelates, hence the name of Bishop's Hatfield, which it retains to the present day. From about the year 1108, which it will be remembered was during the reign of Henry I., it was the residence of the Bishops of Ely until the accession of the Merrie Monarch, but was occasionally used as a royal palace. Edward VI. lived there before he came to the throne in the year 1547, and in the fourth year after his accession conveyed it to the Princess Elizabeth, afterwards (1558) Queen Elizabeth. Even from these brief data it can be gathered that the old palace of Hatfield saw many changes and acknowledged many owners.

At a lecture on the old palace of Hatfield, Mr. Gunton, who can speak authoritatively, said the structure to which we have just been referring was erected by Morton, Henry VII.'s chief adviser, on the site of an earlier erection. Mr. Gunton went on to say, "Only the west side of the quadrangle, which composed the original building, now remains, however, for when the present mansion was built, the other three sides were sacrificed to make way for it. The architecture is noteworthy. Up to that time, as a consequence of the Wars of the Roses, defence was the first consideration in building, but now in these piping times of peace,

comfort being the primary object, the fierce battlements, keeps, and towers developed into mere ornament, so a strange mixture is the result. A specimen of indoor decoration still remains in an old room near the Gate House and tennis court, a black painting on a whitewashed ground. Morton marched well in the van of progress, for the palace was the first large house to be built entirely of bricks. Before this brick chimneys only had been used to stone houses, thus reversing a style in vogue at the present day. It was not until Charles I.'s time that the several apartments were converted into the one great hall as it at present exists." Samuel Pepys' impressions, as entered in his Diary on July 22nd, 1661, are worthy of citation here:—"I come to Hatfield before twelve o'clock, and walked all alone to the Vineyard, which is now a very beautiful place; and coming back I met with Mr. Looker, my Lord's gardener (a friend of Mr. Eglin's), who showed me the house, the chappel with brave pictures, and above all, the gardens, such as I never saw in all my life; nor so good flowers, nor so great Gooseburys, as big as nutmegs."

But if, as has been said, no artificial architectural glories of the Hatfield of olden days remain, many of Nature's monuments stand that must have existed a thousand years ago. These are in the form of Oaks, which are seen on every hand in the beautiful park. A history could, no doubt, be weaved round very many of them, and one at least has a story of its own. This is the celebrated Elizabeth's Oak, of which only about 12 or 15 feet high of shell remain. It is now enclosed by a paling, and one side of the bole has succumbed to the elements, cement having taken the place to help uphold this monarch of its kind. Tradition says that the Princess Elizabeth was seated under this very tree when the news was brought to her of her sister Queen Mary's death, which at once released her from a virtual prison, and made her Queen of England. The story further says that when the news was made known to her, she exclaimed in Latin, "It is the Lord's doing, and is marvellous in our eyes." It was here the Queen first showed that preference for Sir William Cecil, which extended until the statesman's death in 1598. From Mr. Gunton's lecture we also learn that it was in this great hall that Elizabeth held her first reception, and when she appointed Cecil to be her Secretary. In making the appointment the Queen said, "This judgment I have of you, that you will not be corrupted with any manner of gift, and that you will be faithful, and that, without respect to my private will, you will give me the counsel that you think best; and if you shall know anything necessary to declare to me in secrecy, you shall show it to myself only, and assure yourself I will not fail to keep taciturnity therein, and, therefore, herewith I charge you." The historians tell us of his sagacity, and of his close allegiance to the throne of his sovereign, and it may be inferred that the kingdom lost a valuable aid when he passed away. One might enlarge considerably on Hatfield as it was prior to the year 1600; but there is so much of interest to be said of the present house, and its environs, that the closure must be called, or space will not be available for all that ought to be written. It is since that time that the horticultural and arboricultural features have arisen, and to those it is essential that close attention be given.

The immense pile which stands at the present moment is practically as it was erected by Sir Robert Cecil, afterwards first Earl of Salisbury, and second son of the Lord Burleigh of whom mention has been made. It was early in the reign of James I. that this monarch exchanged Hatfield for Theobald's with Sir Robert Cecil, and with this event the connection between the Cecils and Hatfield which continues until now commenced. This nobleman appears to have inherited much of his illustrious father's intellectual gifts, and he it was who completed, in the year 1611, the present mansion. No visitor could fail to be impressed by the monumental size of the structure, which is in some portions so plain and others so ornately beautiful in its style of architecture. With the exception of a portion of the western wing, which was destroyed by fire in 1835, the house stands now as it stood in 1611. It was at this fire that the Dowager Marchioness of Salisbury perished. Since then the structure has been entirely renovated.

It is, perhaps, needless to say that the house is built largely in the Elizabethan style of architecture of red brick, with white stone facings, and is, on the north side especially, severely plain. The south, or principal front of the mansion, is a magnificent example of the Palladian style, and is of great picturesqueness and beauty. The east and west sides are handsome, the former particularly so, as may be seen in the illustration on page 216. We find the following written of the mansion: "The shape of the house is that of a half H, comprising a centre and two wings, the hollow part being turned towards the south. The basement storey contains an arcade with eight arches, divided externally by pilasters. The wings are massive and comparatively plain, supported at each corner by square turrets, 70 feet high to the gilded vanes, the space between comprising three storeys, being relieved by a fine oriel window. The centre tower over the grand entrance, also 70 feet high, is surmounted by a clock." On three sides there are flower gardens, the north side having a large enclosed space, leading from the great avenue to the entrance, but of these features more will be said in succeeding paragraphs.

It was about this period (1611) that the glories of Hatfield, from an arboricultural and a horticultural point of view, obtained ascendancy, and the fact is particularly noteworthy that the first gardener was the famous John Tradescant, or Tradescant. Though in subsequent references this

last established rendering of the name will be adopted, it may be noted that the will of the son of the famous old gardener, who died in 1638, is signed John Tradescant; the period, however, was not remarkable for precision in spelling. Vast indeed must have been the work done by the elder Tradescant, and many tokens of his skill remain at the present day. The magnificent avenue, leading from the north entrance through the park to the Hertford Road, is a lasting memorial to his name. It is gratifying to be able to say that many of the trees, which are mostly Elms and Limes, are superb specimens, and show little effects of the rough buffetings they must have undergone. About three-quarters of a mile from the mansion two other avenues branch right and left. The former of these leads to the old vineyard, not very far from which and adjoining the avenue is Elizabeth's Oak. Near here, too, is an Oak that was planted by our present Sovereign and the late Prince Consort on the occasion of a visit made to Hatfield in 1844. It is a thriving tree; but beside the shells of patriarchal age, and the complete and healthy trees of a thousand winters, it looks a child. A few centuries hence, when perhaps all vestige of Elizabeth's Oak will have gone, that of Victoria will by bearing the brunt of the storm, and the people of the future will weave around and about some charming story of our much-loved Queen. Standing some 20 feet back from the old avenue is a younger one of similar trees, but the object of planting cannot readily be grasped. It was observed that round the bole of each of the later trees a layer of stones had been spread, presumably to keep the roots cool in dry hot weather.

The central entrance to the vineyard was once the house of the gardener—indeed, so recently as during the last thirty years it was occupied. Bearing this fact in mind it is but reasonable to conclude that Tradescant lived here. The vineyard was formed by this famous man about the year 1611 on the northern side of the River Lee, towards which the ground has a natural slope. The number of Vines procured at the outset was 30,000, which were sent over from France, together with two experienced Frenchmen to act as growers. The whole of the vineyard is enclosed by walls, except of course where it is bisected by the River Lee, which was, probably about the same period, considerably widened. It is spanned by two bridges, but neither is within the walls, so that those who wish to cross in the prescribed area must make use of the punt. It was not definitely ascertained how long the vineyard as such was maintained, but probability points to the supposition that it was only for one generation. One can readily imagine that the site was a capital one for the purpose, with its southern aspect and protection from the north and west winds. But after the removal of the Vines the ground, which is of fine quality, was utilised for growing fruits and vegetables for the supply of the mansion. To this purpose the land was put until about twenty-five years ago, when the new vegetable garden now in use was formed. Even now many old fruit trees remain in the open and on the walls as reminders of the past, but with these Mr. Geo. Norman, the present gardener, has nothing to do.

The labours, however, of John Tradescant did not begin and end with planting the avenue and the vineyard, for many other operations were carried out at the time that can be almost definitely ascribed to him. For example, a large belt of trees was planted to protect the mansion from the force of the south-west winds, which come with such terrific strength. In addition to this, he made several journeys to the Continent, notably to Holland, to purchase fruit and other trees for the gardens in his charge, and to him must be given the credit of the introduction of many varieties of fruits that were grown at Hatfield for the first time in this country. It is more than likely that the tastes of the patrons of horticulture in those days differed from those of to-day, and some of them would not now be deemed ornamental; but it is certain that Tradescant carried out many alterations in the style that was then in vogue. Not only is the name of this man perpetuated in the well-known genus *Tradescantia*, but also by a street in Lambeth, where his garden was situated. This was named Tradescant Street, and remains to the present day. Throughout his life he appears to have been closely interested in the study of all phases of horticulture, and his knowledge of earthworks was of service to his country on at least one occasion. From the *Cottage Gardener*, of September 4th, 1860, we glean that Tradescant accompanied the ill-fated Duke of Buckingham, then his employer, in the expedition against the Isle of Rhé. In a dispatch from the scene of operations, dated October 16th, 1627, it is stated: "The winter comes on apace; the men endure much wet in the trenches, and John Tradescant is one of our best engineers; pity our misery."

Then, too, the subject of these particular paragraphs was the founder of the Tradescant Museum, of which frequent mention is made by ancient writers. Of course the contents of this have now become largely distributed, but the residue is preserved in the Ashmolean Museum at Oxford. His collection was said to be of a most interesting character, and denoted a vast amount of energy, skill and knowledge in its compilation. It appears, too, that John Tradescant the younger, whose knowledge of kindred subjects was little less profound than that of his father, continued to add to the museum all kinds of things that would tend to increase its value and interest. John Tradescant the elder, of whom we give herewith a portrait, was, so far as can be ascertained, born in Wiltshire, but the date of his birth has not been traced. Certain it is that he migrated to Meopham in Kent, for in the parish register of that place is found the record of the birth of his son in the year 1608. From here it is probable he was appointed gardener to Sir Robert Cecil at Hatfield, whence he took service with Edward Lord Wotton at Canterbury, whose mansion formed a portion of the ancient convent of St. Augustine.

It was from the garden at Canterbury that Tradescant sent plants to Parkinson, amongst which was the *Tradescantia* of which we have previously made mention. From the service of Lord Wotton Tradescant passed to that of George Villiers Duke of Buckingham, at Newhall in Essex, and after the assassination of this nobleman in 1628 he was appointed gardener to Henrietta Maria, the Queen of Charles I. It was upon receiving this position that he removed to South Lambeth, whence he could have easy access to the Palace gardens. It was here that the museum previously adverted to was formed, and to which he was constantly making additions until his death in 1638. It is recorded that shortly before his demise the University of Oxford purposed to appoint him superintendent of their Physick Garden, which had been established by Henry Danvers, Earl of Danby, in 1632.

Returning now to the vineyard, it may be mentioned that the slopes or terraces on the southern side of the river are fully occupied by various trees;

FIG. 35.—JOHN TRADESCANT.

but these were not planted until a somewhat later date. The formal style known as that of Louis XIV. was adopted in planting. In this Yews are largely comprised, which were clipped and trained to form narrow, secluded avenues radiating from one common centre at the top of the bank to other centres on the right and left hand respectively. Here, too, in all probability was the noted topiary work of which much has been written; but beyond the arcades of Yews, which scarcely come within that category, none apparently now remains. Besides the Yews there are trees of various kinds on this south side of the vineyard, which is now maintained as a pleasure garden. The walks are trim and neat, and the grass is kept closely mown, an operation that must be fairly laborious if one may judge by the steepness of the banks. On the top is a broad terrace promenade, flanked on the one side by dwarf Laurels and *Thuopsis*, backed by the wall, and on the other by the slopes, river, and erstwhile vineyard and vegetable garden.

From the vineyard we traverse a portion of the park, passing the two Royal Oaks on our way. The area of the park in which Oaks abound in very large numbers is about 1000 acres, and many and varied are the views therein. Bracken is in abundance, and deer wander at will about

the broad and undulating surface of the ground. The many Oaks, some of which stand singly and others in clumps of several, are probably relics of an Oak forest that covered the area in much earlier days. Some of them are almost perfect, but several are no more than shells. Though Spruce, Limes, Elms, and other trees find a congenial home in various portions of the park, the Oaks stand pre-eminent as the most imposing features. Where the park is covered with undergrowth and trees broad grass alleys have been formed, which make cool, quiet, and pleasant walks during the hot days of summer. Of these there are presumably several miles, as they stretch away from the avenue leading to the vineyard at frequent intervals and in all directions. It was in this grand park that George III. held a review of the Cavalry, Yeomanry, and other troops in the year 1801, a spectacle that one can easily imagine must have been a glorious one. No place could have been better for such a purpose, the character of the ground and the size rendering it peculiarly suitable. A distance of upwards of half a mile across the parks brings us within the charge of our conductor, Mr. Norman.

Our course has been down the gentle slope of a hill, at the foot of which is a broad and beautiful valley, and a portion of this was until about twenty years ago, an almost impenetrable wilderness garden, with a large area of water in the centre. Now things have been changed, and this pleasure garden in skilful hands has become a charming feature of the place, marred to an extent, no doubt, by the fact that the lake will not now hold water. The undulating banks have been planted with scores of flowering trees and shrubs, as well as forest trees and Conifers, all of which are thriving and growing apace. This portion of the estate must be singularly interesting and beautiful towards the end of April and in May, when the thousands of Rhododendrons will be sheets of beautiful flowers. At the eastern extremity, what was formerly a more than ordinarily neglected corner has been converted into a beautiful retreat by the aid of huge mounds of earth, old tree stumps, Ivy and hardy Ferns. The Ivy rambling over stones, stumps, and banks is gaining the upper hand, but here and there in places where it has been checked the Ferns are growing well. Judging from the age of some of the trees, Mr. Norman supposes that this garden must originally have been formed in the time of Tradescant, or, if not then, very shortly afterwards.

Before quite concluding the references to Hatfield in the past, and coming to the Hatfield of to-day, we should like to quote a paragraph from "A History of English Gardening," a work compiled by Mr. George W. Johnson, and published in 1829, that relates to Hatfield Gardens. It says, "In the reign of Elizabeth arose Hatfield House, in Hertfordshire, the seat of Lord Treasurer Burleigh. Hentzner describes the gardens 'as surrounded by a piece of water, with boats rowing through alleys of well-cut trees and labyrinths made with great labour. There are *jets d'eau* and a summer house, with many pleasant and fair fish ponds and abundant statues,' which he enumerates. There were two parks at Hatfield House, one respectively for red and for fallow deer, also a vineyard that was in existence when Charles the First was detained prisoner there." There is some conflict between the opening sentence of this quotation and the records given in earlier paragraphs, as from these it was gathered that Sir Robert Cecil was the first of this family who owned Hatfield, and this is probably correct.

The gardens of Hatfield as they are at the present day comprise features that are modern as well as portions which have existed since the days of James I., with one or two others whose age will be about a century. As a matter of fact there is a series of gardens on the east, west, and south sides, but not to the north, a representation of which frontage is given in fig. 43, page 217. This is certainly the least interesting side of the structure from a horticultural point of view, for save the little Ivy that can be seen there is nothing to attract the attention. But pass through the handsome iron gates surmounted by the coronet and monogram of the Cecils, and much will be found to examine and to admire. Coming from the pleasure garden already noted there is an easy ascent to the east front of the house; but before it is actually reached we pass the maze of Yews surrounded by a splendid hedge of a similar nature. This Mr. Norman estimates has been formed within this century, and it is the oldest horticultural portion hereabouts. On a rather higher terrace is a broad border now in course of renovation, and which is backed by a wall on which are Roses and many charming flowering shrubs that make a background for the terrace.

Mounting still higher, we soon gain admittance to the eastern garden, with its many beds and palisaded walls clothed with Monthly Roses. Just now, it is needless to say, the beds cannot be gay, but ere long the yellow and red Wallflowers will be in flower, and will diffuse a fragrance that is appreciated by all. Several beds are devoted to these, with others of varied spring-blooming plants, that later will have to give place to the flowers of summer. Though the design of this garden is formal, one can easily imagine that it will be very beautiful during the flowering period of the several plants, and while the Monthly Roses are producing their clusters of lovely blossoms. A broad flight of stone steps leads up to a gravel terrace and the entrance to the mansion, and it is this aspect that is depicted in the illustration (fig. 42) on page 216. This is a picture of historic interest, for it was taken on the occasion of the visit of the Emperor and Empress of Germany to Hatfield in 1891. Examine the illustration closely, and the Empress, with the Marchioness of Salisbury,

will be seen passing down the centre of the terrace, while beyond the Emperor may be observed talking with the chief of the German Legation. His Imperial Majesty may be distinguished from the fact that he is the only person represented who has had recourse to the homely "bowler" hat. Descending the steps from the mansion is the Marquis of Salisbury, who is entertaining the Royal visitors and others at a garden party. This illustration may well be examined a second time, for on the right can be seen the famous avenue of which we have spoken as having been planted by Tradescant the Elder. Thus the photograph is historical in more respects than one.

Not that these are the only Royalties who have honoured Hatfield. On the contrary, all who have visited England seem to have made a point of going there. Her Majesty has been twice; once, as noted, with the Prince Consort in 1844, and again during the Jubilee year (1887) of her reign. The Prince and Princess of Wales have frequently honoured

Elsuen & Son, Hertford

FIG. 36.—MR. GEO. NORMAN.

Hatfield by their presence, as have other members of our Royal family. Then, too, the Shah of Persia was a guest, as were the Prince of Naples, and last, but not least, Li Hung Chang so recently as 1896. It was then that a daily contemporary said, "Li Hung Chang may well describe his visit to his fellow countrymen on his return in the words of an old author as to Sir Robert Cecil's entertainment of King James I. and King Christian of Denmark in 1606, for Hatfield traditions of hospitality know no change." The passage referred to runs:—"Upon this occasion there wanted no means either of device, pleasure, entertainment, feasting, or what else might glut the heart with contentment but was there with the most liberal hand and willing heart and contented spirit poured forth. No man was reprehended for giving, but many for not taking."

Before the principal entrance on the south front of the mansion is a somewhat extensive flower garden laid out in geometrical design, and in which the beds have all stone edgings. Many of these are of considerable size, and for the winter are occupied by small evergreens with bulbs between for a spring display, to be followed later by thousands of summer flowering plants; but these will not take their places yet for some time to come. There is, too, in this, as well as in each of the other gardens, a considerable proportion of grass, all of which is kept neatly mown throughout the summer months. Extending from the southern entrance for a considerable distance is a grass drive, flanked by rows of trees which have a magnificent effect during the spring, summer, and autumn

months. From the main door this gives a grand view to the woods beyond. On this side of the house Roses, Magnolias, and other climbers ramble, one specimen of *Magnolia conspicua* being superb. Its branches extend to a great height, and are roped with thousands of buds and a few already expanded flowers.

On the western side of the house there are several of these enclosed gardens, comprising mainly herbaceous plants, though Roses have a division to themselves. Two of these gardens are noteworthy—one from the style of planting, and the other from the time of formation. The first is a creation of Mr. Norman's, and is laid out in beds full of herbaceous perennials. In the centre is a large basin and fountain, to the edge of which the grass reaches. The sections of the garden all converge towards this central fountain, and each bed in every section is planted with one colour only. Thus there are blue, red, white, yellow, pink, rose, and purple beds, planted so as to form contrasts, and producing an effect that is quite unique. The second garden is of much earlier date, for it was formed during the time of King James I. Round the outside of it—the centre is grass, and beds, as in the cases named—runs an arcade that has been formed of Limes, while at each corner is a Mulberry tree that was planted at the same time. It is probable that the making of this garden was contemporaneous with the planting of the great avenue, and would therefore be done by Tradescant. The canopy of green makes a cool walk during the hottest summer day.

Running parallel with the western terrace is a broad asphalt promenade divided from the fields by a splendid Holly hedge. This is about 5 feet in height, and several feet in thickness, and throughout the whole length of upwards of 100 yards not a single weak place could be found. To the right as one stands on this terrace facing the town of Hatfield is the church, which was restored by the Marquis about twenty-five years ago. It is a noble edifice which, standing high, can easily be seen from the railway that runs at the foot of the hill. The old palace, tennis court, and gate house, to which attention has already been called, are also very close to the church and promenade, while to the left are the kitchen and fruit gardens, together with the hothouses, and to these we will now wend our way. Many are the splendid trees beneath which we have to pass in variety that is well nigh endless, and of a beauty that we shall not attempt to describe. From the old and interesting we turn, reluctantly perhaps, to the new, interesting, but none the less, utilitarian department.

The mention of the church reminds of another jotting of Pepys in his famous diary, August 11th, 1667:—"And so to Hatfield, to the inn, near my Lord Salisbury's house, and there rested ourselves, and drank, and bespoke dinner; and so to church. In this church lies the former Lord of Salisbury (Cecil), buried in a noble tomb. Then we to our inn, and there dined very well, and mighty merry; and walked out into the park through the fine walk of trees, and to the vineyard, and there shewed them that which is in good order, and indeed a place of great delight; which, together with our fine walk through the park, was of as much pleasure as could be desired in the world for country pleasure and good ayre. Being come back, and weary with the walk, the women had pleasure in putting on some straw hats, which are much worn in this country, and did become them mightily, but especially my wife."

It is only natural where such a large establishment as the one of Hatfield is maintained that the supplies of vegetables, fruits, and flowers of all kinds are enormous. For example, the kitchen garden department has already sent to the mansion since the new year 15,000 heads of Asparagus, and all other kinds are in proportionate demand. The new vegetable and fruit garden was formed just prior to the time of giving up the one in the vineyard, and comprises about 7 acres within the walls and some 4 or 5 acres round the outside. Thus there is not too much room for the quantities of fruit and vegetables that are required, and the closest system of cropping has perforce to be adopted. The soil does not look at all "kind," but we were assured by Mr. Norman that with good working and plenty of manure all kinds of vegetables could be produced of excellent quality. There are immense quarters devoted to Asparagus and Celery, while Peas in about half a mile of rows are well above ground. All the green vegetables with the valuable root crops are largely cultivated, as are the various saladings. Tomatoes and Cucumbers in the houses look remarkably well, and the latter have just reached the fruiting stage. The Asparagus roots are lifted successively, and are forced in the beds of a couple of houses. Young Carrots in the frames are looking well, and the sweet, tender roots will be very acceptable. The walls that surround the kitchen garden are all built of concrete, and are not therefore likely to perish. Of course, it being impossible to drive nails into the walls, they have all had to be wired, and there is now growing on them as fine a collection of fruit trees as anyone could wish to see. They are clean and healthy, having no signs of insect pests, and we can readily accept our guide's assurance that they produce grand crops of fruit. Mr. Norman is very emphatic in his praises of the wired walls, considering them in all respects preferable to those that necessitate the use of nails and shreds. Besides these trained trees there are others on the stables and the tennis court, while in the open there are large numbers of Apples and Pears, as well as Plums, Damsons, bush fruits, and Strawberries. All look well, and show evidence of skilful attention to their requirements.

Under glass fruit is as carefully tended as that which is grown out of doors, and the results attained are equally as gratifying and satisfactory to everyone concerned. In all there are seven vineries containing the customary varieties, and it is the boast of the grower that for sixteen years he has never been without Grapes for a single day. His pride on this point is quite pardonable, for it is an achievement deserving of all praise. At the time this visit was made there were in the Grape room just over 100 bunches. The roots of all the Vines are both inside and outside of the houses, and the borders inside have to be utilised for bedding plants during the resting period. Every two or three years the borders are extended a little by the addition of squares of excellent loam. Of the remaining fruits under glass the most notable is a Royal George Peach, which was planted by the present gardener just twenty years ago. For sixteen years an average of 300 fruits per annum have

been gathered from this tree, and in some seasons there have been as many as 400 good specimens. In round numbers this gives 5000 fruits from one tree, at which even the most hypercritical would scarcely grumble. The tree is not yet exhausted; in fact, it is in the best of health, and has now an enormous number of fruits set for the coming season. The wood is clean, straight, and not very large, while the flowers are perfectly developed. It occupies one side of a low span-roofed house that is about 50 feet long.

The number of houses devoted to plants is very considerable, and these are augmented by long rows of frames and hotbeds, where Violets, Carnations, Chrysanthemums, and Cyclamens are accommodated. All the plants grown are chosen with a view either to supplying cut flowers or for the purposes of house decoration, and for the latter purpose everyone knows exactly what would be selected, so none need be named. Of flowering plants those are mainly chosen that produce fragrant flowers, such as Lily of the Valley (now being in great demand), Hyacinths, Carnations, and the many others that will occur to the minds of readers, and call for no special mention. Roses have a bed in one of the span-roofed houses devoted to them; in this the plants are pegged down, and during the year many thousands of flowers are cut therefrom. All the varieties are such as produce blooms suitable for button-hole bouquets. The cleanliness of every plant in all the many houses is worthy of remark, for no vestige of enemies of any kind could be discerned. To a large extent this, without doubt, accounts for the fine condition of the plants. The woodwork, walls, and glass are also, and wisely, kept as clean as possible. The conservatory, referred to as being within sight of the trains, is a long, comparatively narrow, corridor-like structure, with a central bay. This is now very bright with Camellias, of which the large shapely plants are producing thousands of variously coloured flowers amidst the glistening

green leaves. They are very handsome, and remind of the Waltham Cross collection of Mr. William Paul, whence perhaps they came. Between the Camellias, which are planted out, are some of the finer-growing Bamboos, and these enhance the general effect.

The task is almost done. Hatfield has been spoken of as it was 300 years ago, and as it is to-day. Much more could be said without doing adequate justice to this grand estate. However, the future holds many possibilities, amongst which may come the opportunity of a second visit to Hatfield. Let us hope it will, for it is certain that, considering the interest in horticulture and allied subjects possessed by both the Marquis and Marchioness of Salisbury, there will be no deterioration in such interest and no diminution in the beauty of its many and varied features. We have pleasure in giving the portrait of Hatfield's past-master gardener of 1611—Tradescant, and also that of his successor, after nearly three centuries—Mr. George Norman, who for twenty-two years has been entrusted with the management of these gardens, and who throughout that time has proved himself fully equal to his great and responsible charge.—H. J. WRIGHT.

FIG. 37.—ESCAPING VINE ROOT.

INSIDE AND OUTSIDE VINE BORDERS.

SOME very sensible remarks have recently appeared in the Journal from Mr. Temple and others on the always interesting subject of Vines and Vine borders. Perhaps a few more remarks may not be unacceptable to some of your readers. In many cases Grape growers have to trim their methods to suit peculiar conditions that are not, as a rule, taken into account in ordinary treatises on Grape culture, hence the desultory remarks of cultivators are calculated to serve some useful purpose.

As to the comparative advantages of having the roots of early forced Vines entirely restricted to an inside border over that of their having also the run of an outside border, it may be said that it is a question on which it may be well not to dogmatise, as so much depends on other conditions that may be peculiar to individual cases. There can be no question as to the desirability of having the roots of Vines that have to be forced to ripen Grapes in April and May well established in a good inside border, and if it is intended ultimately to let them into an outside medium they should be compelled to first take good possession of the inside border.

For my own part I have a bias—if it may be so termed—in favour of the double run. It is easy to have Vines well established inside before letting them work outside. This can be done by building up the openings in the front wall, and when these are opened to let the roots out it is well not to remove more of the brickwork than the two top courses, so that the roots go out near the surface of the border. Vine roots, if left to themselves, seem to have a predilection in favour of an outside border and of proceeding in the opposite direction to the rods, and soon find their way outside. Indeed, ordinary brick and mortar work is not a sufficient barrier to their doing so. Nothing short of cement joints can baffle their efforts to get access to an outside border. This natural course is worthy of being noted, and may be considered as pointing in favour of an outside as well as an inside border, no matter what may be the date when ripe Grapes are required.

The Editor has sent me two very interesting illustrations, that may be regarded as proofs of the foregoing remarks as to the strong bias Vine roots have for outside borders. They are certainly very striking examples of the determination and power that Vines exert in carrying out this bias. As the illustrations demonstrate, they have forced their way through a 9-inch wall, and flattened themselves abnormally in the process. Mr. W. Taylor, gardener to C. Bayer, Esq., Tewkesbury Lodge, Forest Hill, who won the silver medal of the R.H.S. last year, has charge of the Vines in question. He also was the winner of a special medal at Beckenham. The illustrations are just half the size of the persistent roots.

Of course if the outside border is to be of the greatest possible service to the Vines and crop, it should be managed on certain lines. The well-known fact that the temperature of the soil in early autumn is warmer than that of the atmosphere ought to be sufficient reason to lead the cultivator, who elects to have the assistance of an outside border, to take the best means to conserve its heat, and not allow this natural warmth to be, so to speak, stolen away by the chilling blasts and rains of autumn, before taking timely measures to retain it. A good way of effecting this is to cover the border early in autumn with some loose non-conducting material, such as dry leaves, hay, or straw, and the whole with a thick thatch of well-drawn straw, to throw off all rain and searching winds.

FIG. 38.—ESCAPING VINE ROOT.

I have had a striking experience of the extent to which heat can be husbanded, in the case of a Vine border from which I was in the habit of ripening Grapes by the last week in April, and where circumstances did not allow of any inside border. I uncovered part of the border at its middle in February, and plunged a thermometer in it to the depth of 16 inches, and found that in a very short time it raised the mercury from 40° to 60°. This border was well raised above the

September, and which, of course, did not require much fire heat. One limb of the Vine ripened its crop in the early division in April; the other limb in the late division did not ripen, as I have noted, till September. In the early house the bunches were compact and moderate sized, and there never was a shanked berry in them; in the cool house the branch of the same Vine produced much larger but looser bunches, in which there was always more or less shanking.

FIG. 39.—LAWN SECTION—A, LEVEL TERRACE; B, SLOPE; C, END OF FALL; D, WALK; E AND DOTTED LINE, LEVEL

ordinary ground level, had a more than usual slope to the front, and was always covered, as indicated above, early in autumn.

The late Mr. Thrower, who for so many years grew very superior early Grapes at High Canons in Herts, to my knowledge ripened nineteen crops in succession of Black Hamburgh Grapes from the same Vine in ainery where there was no inside border, and where the outside one was covered as I have described. In spite of all this I would much prefer to have an inside border, while at the same time I would not like to be without one outside also, even in the earliest of forcing. Admitting that the roots in an inside border are so circumstanced that they respond more readily and effectually to their task than those in an outside border, yet the latter respond with their aid at a time when it is most required. I question, however, if the outside border be properly managed, if they are far, if anything, behind those inside in starting to their work. It is a nice point that I have never proved.

As a rule there is not so much call for very early forcing now as there was before long-keeping Grapes came on the scene. It is now a

The cause of this difference of the size and shape of bunches arose from the different degrees of ripeness to which the two branches attained.

Shanking is no doubt the result of different causes. Still, I cannot help thinking that the build or shape of bunch has something to do with it. This is what may be termed to some extent a vexed question. I have, however, noticed that, on Vines in the best condition and not given to shanking generally, when a loosely built bunch has been left, that bunch, and that only, on a given Vine has shanked. If this be one of the things that cause shanking, the remedy of ripening the Vines so as to produce compact bunches points to the cure of this predisposing cause.

Before closing these desultory remarks, it may be of service to some of your readers to call attention to the practice of some growers in mulching Vine borders when fire heat is not applied to the houses till, say, the 1st of March. I have seen the borders of such Vines covered with a considerable depth of cow manure in December and January. Surely a little thought should be sufficient to guide to the conclusion

FIG. 40.—LAWNS - POINTS (1) AND PINCUSHIONS (2)—BAD.

FIG. 41.—LAWNS COMMON SENSE CURVES—THE BETTER WAY.

comparatively easy and common thing to have good old Grapes till June; still no Grape suitable for early forcing or for late keeping can compete with Black Hamburgs for quality, and it is not a difficult matter to have them fit for table in May. The pity is that other comparatively coarse sorts have ousted them so much out of their place in autumn and early winter.

I should like to refer to a rather interesting experience I had in connection with early forcing in the case of the outside border that I have described. One of the Vines was planted near the division which separated the early from a house where the crop was not ripened till

that this is not good practice. Such a mulching at such a time is, to a great extent, wasted, and is a poor non-conductor of heat. It is much better to cover with some loose litter or straw at the time named, and when the sunshine of March to June is acting beneficially, to draw off the straw by day and replace it in the afternoon to conserve the heat. When the Grapes are thinned and the roots active is the time to apply rich mulching and top-dressings, which nourish and conserve moisture, and thus attract the active roots to the surface. Coverings and uncoverings of straw in spring have a wonderful effect in warming the soil. By such practice, the great growers for London and other

markets produce Radishes early enough to realise £40 an acre, instead of £15 without the use of straw.

Mulching outside and inside borders with close mortar-like manure when carried to excess, especially on inside borders, results in bringing the soil into a condition that is not conducive to the health of Vines. Inside there is a comparatively stagnant air, and the borders often receive less pure water than is desirable. Outside there is exposure to all the winds that blow, and to all the autumn and winter rainfalls. These rich mulchings, and more especially when accompanied with liberal applications of liquid manure, have a tendency to what in common phraseology is termed souring the soil; in other words deleterious acids accumulate in it to an injurious extent. The rains help greatly to get rid of these in outside borders and keep the ground "sweet" and healthy. May not this have something to do with the instinct-like tendency of Vine roots to escape into the open air border?

When I left the driest district in Great Britain to practise in one of the very wettest, in which I have seen January and December give 25 inches of rain, I adopted measures to throw the winter rains entirely off some of the Vine borders. Not a long time was required for showing that those covered were not in nearly so satisfactory a state as those exposed to all the rains that fell. Years after the time I have referred to, the late Mr. Honeyman, whom I had much satisfaction in enlisting as a horticultural writer, treated in the "Gardener" and the *Journal of Horticulture* on the subject of injurious accumulations in highly enriched soil being washed away to a large extent by heavy rains. D. THOMSON.

LAWNS AND ALLIED SUBJECTS.

(Continued from page 184.)

IN a study of the position which may cover some considerable extent of ground, appearances at first sight may be very deceptive in the matter of levels, and if the work is commenced without including the whole area in the calculation, it may commence very well indeed, but end very badly, involving a serious expenditure of preventible labour. Among many examples, some of which have come under my hands, and more under observation, I have never dealt with or seen parallel cases of treatment, hence a special study of each, including the house, the grounds, and the desire of the owners, which, indeed, may be general enough to allow of good taste and sound judgment meeting all requirements at a minimum of expense, as all are factors to be taken into account. Outlines, however, sufficiently elastic may be given to suit most cases.

The principal frontage, usually termed the garden front, may chiefly engage our attention, and in most cases this will face to the south, with possibly a point or two either east or west. If architectural forethought in the choice of position has done its duty by the house, as a gardener may hope to do his by the grounds, these will fall from it instead of towards it. A gentle fall to the south or south-west is an ideal position. Supposing the house to stand upon a plateau, part of which forms a terrace, our lawn in proximity to it is probably the only portion it is either necessary or desirable to make truly level, for a dead level lawn is seldom desirable. Longitudinally, however—viz., running east and west, supposing the position to be due south, the true level is essential for a given distance.

An illustration (fig. 39) shows where the grass, A, commences on the terrace, which, being a part and parcel of it, will be perfectly level; B, a slope, is the connecting link with the body of the lawn. A well made slope is not only a point of beauty in general effect, but is often the key to labour-saving in the matter of levelling, according as the fall of the ground demands it. The slope, if at not too sharp an angle, will be such as a skilled labourer will easily mow with a hand machine. Apart from Italian terrace work, this may be again repeated if occasion warrants it, and may, or may not, include the provision of grass steps (which will be treated of in due course). From the slope our level, always correctly preserved longitudinally, will gently fall, according to the requirements of the particular case, as at C, this fall being about 1 in 30, until a supposed boundary walk is reached, D, which finishes what may be termed the lawn proper, although beyond that, at E, more kept grass is present, either at a true level, as shown, or still gently falling away. One instance I know where with this finishing margin the reverse occurs, and it is made to fall to the walk. The effect of this from the windows is not good, tending to a foreshortening.

A phase of bad treatment may now be shown, in order to avoid—viz., cutting up into sharp corners, or elongation into puerile points at the junction of walks. Where walks join at right angles this is less conspicuous, but we are now dealing with the more picturesque freedom, employing curves and graceful outlines, and where caprice more than common sense is not rarely to be seen. Fig. 40 illustrates what is meant relative to the bad system, and fig. 41 the better way. —SYLVA.

(To be continued.)

SEAKALE CULTURE.

THERE can be no question as to the wholesomeness of this excellent vegetable; in fact it has many good qualities to recommend it, the first and foremost being that it is available at a season when other fresh vegetables are oftentimes very scarce. Many vegetables have a tendency (when forced) to taste earthy or insipid, but Seakale I hold to be an exception to this rule; for when grown in any ordinary way out of doors, with full exposure to the atmosphere, it loses that crispness which is its most essential point of merit. Therefore this vegetable is much improved by forcing, always provided that artificial heat is not used to excess.

Slow and careful forcing must be accorded, especially for the first crops. The reason of this is at once obvious, for, like all plants, Seakale requires rest; and as this does not take place until October, and even later than that in some seasons (notably 1897), it is not to be wondered at if the plant resents being urged into activity a week or two after that time. The crowns should have at least one month complete rest, otherwise it will be found that the young shoots will be more like straws than Seakale. After the end of January the crowns will endure more urging. Generally speaking some part of the Mushroom house is available for the purpose, while in some places where this vegetable is extensively grown there are heated pits or boxes to receive the roots, and when these are at command it is a comparatively simple matter to keep up an unbroken supply until late in the spring.

Forcing in the open is resorted to here for the late supply, the crowns being planted in a double row at about 1 foot apart each way, and early in the month of February are covered to a depth of about 15 inches with Mushroom bed refuse in the form of a ridge. The gentle heat imparted by this material appears to suit the Seakale admirably, for the heads of the plants push through, and produce fine, stout, and clean Seakale, which is much appreciated. We usually leave these plants on the same spot for two years, after which they may be removed and replaced with young plants. Some growers prefer to raise annually from seed, but we find the old-fashioned plan of growing from sets answers our purpose better. These are broken off in lengths of about 3 inches, selecting those about the thickness of one's forefinger in the autumn when lifting. They are then stood in rows in sandy soil, where they remain until they commence to break, after which we transfer them to their permanent quarters. We successfully force 3000 crowns annually by the methods laid down.—H. T. M., Stoneleigh.

A FRUIT PEST.

THE Gooseberry saw-fly (*Nematus ribesii*), which levies such exorbitant tithes on one of our most popular fruits, is generally described by naturalists as a pretty and merry little insect which passes its brief life in disporting with its companions in the sunshine. We might to a certain extent concur in this eulogistic estimate were it not the fact that in another stage of its existence it literally plays "old gooseberry" with the fruit from which it takes its name, and it is doubtless from its devastating proceedings in this connection that the expression, as quoted, originated.

From a gardener's point of view, its merriment at any time is sadly out of place, inasmuch as there is not a more destructive little fellow to be met with in the whole list of garden pests, and it certainly requires a perfect stoic to maintain even a cheerful or calm demeanour when viewing its depredations. The eggs are deposited on the backs of the Gooseberry leaves at regular intervals like beadwork. In about a week the grubs issue head foremost, leaving the skins of the eggs standing like a row of empty silver purses, and straightway they fall to eating, and this with such appetite that the effect of their first meal alone changes their smoke-coloured vests into positively a doublet of Lincoln green.

There are some sixty or seventy of these voracious little insects on a leaf, and as each grub will eat three leaves to its own share before being fully fed, it follows that by destroying one infested leaf a couple of hundred are saved. If left alone, however, to pursue its inclination, the grub will go on eating without intermission until developed into a length of half an inch. The black head then separates like a mask from the neck and splits down the middle, a new head shooting up from the opening. The entire body is next wriggled out, and at length, having got rid of the embarrassing skin, the caterpillar sets to work to fill the new one, eating without intermission for several days. At the end of this repast the skin is again cast, and the still larva remains of a pale delicate green colour. Eating days, though, are numbered, and descent is made into the earth to the depth of a few inches, when a little oblong cell is formed, and then, surrounded with a tough black cocoon, the next transformation is awaited, which is into the chrysalid state, and then finally into a fly *de novo*.

When the eggs are laid in the month of May the whole of this natural history down to the appearance of the fly occupies the space of about a month; but at times, when the eggs are deposited late in the year, this intelligent grub does not emerge from its subterranean abode till the following spring. If there be found, as well may be the case, any gardener so inhospitable as to desire to save his Gooseberries at the expense of this so-called interesting and amusing visitor, the best way apparently for him to proceed would be to beat down and harden the soil all around the bushes, so as to convert the intended temporary retirement from the pleasures of the world of this representative old gooseberry into that term known to the law as "his natural life." —WM. PHILOSOPHY IN GARDENING.

Is there any? What is it? In order to start upon the level ground of reason it is important that no misconception should handicap the effort to run beyond dispute, and it will clear the way considerably to have the simplest definition possible of the term philosophy. Possibly there are as many so-called philosophies as there are varieties of Potatoes, but after all the one is philosophy, the other the Potato till the end of the chapter.

For present purposes our subject may be divided into two phases, the one in direct relation to garden work, the other more or less so to the worker. These harmoniously blended represent, to my mind, the highest potential of power that the worker can wield. Some there are, perhaps, who have little or no faith in things they can neither hear, see, smell, taste, nor feel, and one cannot but admit that it is the commonest of common sense to find in the senses a proof of existence; but it appears to be the vague application of the term which is at fault, resulting chiefly in an intangible quantity that some practical men will have none of so far as gardening is concerned. Others, with more faith and probably less reason, have regarded it as a kind of sterilising substance detrimental to the felicities of life.

In a standard work, "The Imperial Dictionary," philosophy is described as "the hypothesis or system on which natural effects are explained." Gardeners dealing with the best illustrated work of Nature, so far as its flora is concerned, have, I think, every right to be placed in the higher ranks of the great school of philosophy. "The Imperial Dictionary" also informs me that to reason philosophically is to reason "calmly," "wisely," "rationally," and conclusively settles the question of meaning, so far as we are concerned, by further stating "it is to search into the reason of things; to investigate phenomena, and assign rational causes for their existence." To sum up the matter in a few words, philosophic inquiry is the searching for truth, and the aim of the philosopher is to find it.

The object of this paper is rather to show the value of philosophy relative to our work, and its influence over the worker, than to prove the existence of what probably but little real scepticism obtains, any that does remain being accounted for by a conservatism which confines it to the higher exposition—viz., that in which the mind is engaged in the analytical researches of its own attributes, such as is exemplified in Locke's "Essays on the Human Understanding." Beyond this there are but the dizzy heights leading to the First Great Cause that few dare explore. It is, however, a pleasing task to work out the connection with, and trace the bearings of, our subject relative to gardening and gardeners.

THE WORK.

To work upon philosophic principles is to understand and to obey certain natural laws; and in this intelligent recognition and obedience is derived the power to command success. All else is chance, and chance is often the road to chaos. Whether it is an Orchid or an Apple tree, a Mushroom or a Mangold, all equally important in their way, they are subjected to certain natural laws of life which may never be ruthlessly broken or seldom evaded with impunity; in fact, if we treat them philosophically we treat them rationally, and, as a rule, successfully. Any exceptions—failures—must proceed either from a subversion of those laws, or from one or other of those peculiar natural methods employed for a higher design than enters into the scope of our mental vision.

"We know all this; it is what every intelligent worker brings into his practice," may be remarked. Exactly so. But there are a few things, and rather important ones too, which are apt to be overlooked. There are more things that enter into our work than in our philosophy. Many men, many methods—various means to the same end. Foresight keeps the one object in view, but views it from different angles, each angle being represented by certain local circumstances which all the windy argument available will never square one with the other.

In our prospective reckonings we too often calculate without our host—Nature; for in the sum total of those computations not only is all that is probable to be taken into account, but all that is possible may not wisely be ignored. If success in any particular direction is not achieved it is either that the estimate has been too high or that something has been omitted in the calculation, for it must be admitted that there is a cause for every effect, be that effect what it may. Apparent inconsistencies will disappear if the subject is considered comprehensively.

We may say—do say—that all calculations are liable to be upset by the forces of Nature; by the May frost which comes in every, say, three or four years, or the hailstorm to smash the glass once in a decade; but what has happened is always liable to be repeated whether on the larger scale of a cataclysm or the smaller—the catastrophies—we are dealing with. The wise man never omits them

from his estimate, making due provision with his covering material against the frost, and with the insurance company against the hail; hence his reckonings cannot be upset, and the foolish man, having not calculated upon these always possible contingencies, the upsetting of his calculations are out of the question. If he calculated to escape, then, indeed, he reckoned without his host, who is too imperious to be so slighted. It is a grand thing, doubtless, to trust in providence if, and I trust no wrong inference may be drawn in saying so, if it is the providence of bast mats and hailstorm insurance premiums, otherwise it is merely tempting providence and courting the catastrophe. In the first instance I hope to have shown that positive philosophy was evident with the wise man, and sufficient of the negative kind in his antitype to point a moral.

When planting a number of common Laurels some years since I was asked what they cost. "Sixpence each," was the reply. "Oh, I bought a quantity from So-and-So, even larger than those, at the rate of a penny each; you know he is not a professional nurseryman, and does not look for large profits." The result was, I sent for 500; they proved to be straggling things, which had never been transplanted, with a few thongs where a mass of fibrous roots should have been; in fact, dear at the price. I need hardly say that the extra fivepence paid for the good plants partly represented the care and labour spent in consecutive replanting, with the necessary time taken to build them up, and the space required for doing so. In regarding the matter philosophically the plants were full value for the money.

Within the radius of my gardening world is an amateur rosarian who says, "I must have Roses, but I have to buy in every year. My soil is bad, I think; and I fear my man does not understand them, for I can never grow them like yours." He is fond of his Roses; but above and beyond that is his love of a bargain (?) So each spring finds him at a certain auction room where "splendid (?) stuff," the clearings of some nursery plot, is obtained for a "song," to the joy of the frugal mind. It would be better for this gentleman, who really loves his garden; and for his man, who loves his work, if a little philosophy went into his Rose dealings. I will not say that what is cheap is not always honest. He probably gets his money's worth, but no more, for the money in this case, both literally and figuratively, represent very little. So I take it that there is philosophy in a Laurel, in a Rose; in fact all through garden work, which, having to reckon with a philosophic Editor, must no longer detain, so I hasten to conclude with

THE WORKER.

If we could understand ourselves as well as we understand our plants, there would, perhaps, be fewer blighted lives and less need for any remarks here. "An Old Provincial" has so ably and so pertinently pointed a moral on page 166, that whether he will or will not allow the existence of what not a few deny, I regard him as a Knight Grand Cross of the noble army of philosophers; the garden variety, of course. This "provincial" philosophy, which few could read and interpret, "calmly," "wisely," "rationally," without both pleasure and profit, lightens my labours considerably. The way in which the chivalrous knight dashed in upon two good men and true, playing a little at cross purposes, and switched them safely and comfortably upon parallel lines, without wounding either, afforded me delight, and he is "An Old Provincial philosopher" to me henceforth.

There is, I believe, more philosophy to be found in a flower show—that is, in the showers themselves, in their victories and defeats, than a whole series of philosophical lectures could exhibit. Now and again we find a defeated man impartially tracing the effect to the cause, and duly and deliberately reorganising his plans for another campaign. He is a grand type of the British gardener, but his presence is rather the exception than the rule. Cause and effect! How hard it is sometimes to trace the connection, but by all the ethics of natural philosophy—of truth, it is there. Men may deceive themselves, but this never can deceive them. It is the lifting of a big cloud of illusions. Passing strange it is to see how comfortably we clothe ourselves in the fancy garments of spurious reasoning; anything rather than the bare truth, which is as plain as a pikestaff when the air is cleared of hallucinations, and reason occupies her throne.

"Very sad," we too often have to hear, that "So-and-so," a well known name in the gardening world, is applying for the benefits of the Gardeners' Royal Benevolent Institution. Sad, in a way, surely; but sadder by far to see men deluding themselves by the false hope that such a fate is impossible to them. Is there no moral conveyed in the story of a broken life, the effects of which are so visible? the cause of which delicacy forbids us to seek. The man who reasons calmly, wisely, rationally, cannot shut such possibilities out of his calculations—ergo, he is calm, wise, rational; he is a philosopher, but he is, too, alas! the exception. But what of the great majority, what are they?

Philosophy in gardening? Yes, certainly, and room for more. Let no one think it a phantom or doubt its verity. There is no false philosophy, for there can be no false truth.—THE SQUIRE.

A DAY IN OLD ORCHARDS.

ON page 26, January 13th, I gave such advice as seemed called for under the circumstances in dealing with two out of five orchards that were visited, reserving further observations on the other three. When it is possible to improve old fruit trees it is wise to do so, in order that they may afford supplies of the best fruit they are capable of producing until the young trees, which should always be planted at the time of renovating the old, attain a fruitful condition. Making a clean sweep of all old trees because they are not capable of bearing anything like first class fruit has often proved a mistake. On the principle that half a loaf is better than no bread, so is a supply of second or even third-rate Apples for cooking better than none at all in establishments where a considerable bulk is needed for consumption.

No. 3 Orchard was very much like No. 1, described on the page above quoted. A grove of trees on one side was pronounced worthy of thinning and cleansing if the varieties were fairly good, but if not, work would be wasted on them, and grafting some of the healthier would be preferable. The body of the enclosure consisting of trees, practically "eaten to death" with canker, would pay far the best by clearing entirely, adding basic slag, kainit (or wood ashes), and deep cultivation as previously advised.

If planted with standard Apples, it would be desirable to choose strong or free growers, such as Alfriston, Bramley's Seedling, Lord Derby, Golden Noble, Warner's King, and Newton Wonder for cooking, with Blenheim Pippin, Devonshire Quarrenden, Cox's Orange Pippin, Gascoyne's Scarlet, and Cackle's Pippin for eating, planting them 30 feet apart, with Plums half that distance asunder between them. Plums often succeed better on the site of an old Apple orchard than Apples do, but strong growing varieties in deeply worked and fortified soil often answer very well.

No. 4 Orchard.—Site wet; young trees making long annual shoots should be carefully dug up and replanted in fresh soil containing lime and burnt refuse, the roots spread out on the surface level of the present ground or slightly above it, and when covered to stand on mounds. The surface of the ground ought to be kept free from grass and mulched with manure on the approach of hot dry weather, not before, leaving the material to decay. Basic slag and wood ashes would act beneficially. The long young branches ought to be shortened to effect a balance with the shortened roots; then if the trees were kept clear and surface rooting encouraged by summer mulchings improvement would certainly follow.

No. 5 Orchard.—No, not quite an orchard, but large individual trees of Ribston Pippin and Cackle's Pippin, isolated in a meadow or pasture. They are large and old, but capable of material improvement by the removal of a great amount of worthless wood, cleansing the remainder, and nourishing the roots. The branches have probably been thinned at some time, and the bristling shoots resulting allowed to struggle with each other till the trees are mere thickets. The resources of the soil have been spent on a mass of wood that not only could give no return in fruit, but had deprived the other parts, which had forced themselves out of the crowd, of sustenance.

AS TO PRUNING.—Superfluous branches should not be shortened, but cut out close to the main stems, and when a saw is used paring smoothly after it with a sharp knife. The whole of the interior wood ought to come out, and only those parts retained the leaves of which are fully and directly exposed to the action of light. There should be absolutely nothing between them and the firmament. That is a very important matter. Leaves made in the interior of a tree are worse than useless. If the winter pruning has not been sufficient for preventing summer crowding, thin out further when the trees are in leaf.

SPRING DISBUDDING.—When several branches have been removed from the interior of trees in winter—cut off close to the main stems as above indicated—in all probability about the end of April, or later, clusters of fresh growths will push from round the pruning "cuts." It is imperative that these clustering growths be rubbed out when they are an inch or so long, or the trees will soon be as much choked with useless wood as before. These interior growths are robbers, as they divert the nutriment supplied by the roots from the exposed branchlets, where alone it can be turned to profitable account in the production and development of fruit.

AS TO CLEANSING.—Not the main stems alone, but the small branchlets to the very tips should be cleansed of all incrustations. This can be done in two ways—1, Washing the trunks and main stems with brine or tolerably hot limewash; then, before the buds swell, dusting all other parts with newly slaked lime when the trees are dripping with wet on a calm misty morning. A man and ladder, with a basket of lime in one hand, with the other dashes the lime among the branches—upwards, downwards, sideways, everywhere, driving it well among the spurs and buds. This adheres, and the rubbish peels off, while the lime which falls to the ground during the application is there beneficial. That is one way, and though good

is not the cleanest for the worker. Another and an excellent method of cleansing trees is as follows:—

CAUSTIC WASH.—For making 10 gallons, the original plan, which has answered well, was to dissolve 1 lb. each of caustic soda and pearlsh, and mix in the above quantity of water. Another method of preparation, described by Mr. Cousins in his "Chemistry of the Garden" Primer, has been found by him still more satisfactory. It is made by first dissolving 1 lb. of the caustic (commercial) soda in a pail half filled with water, then stirring into the liquid three-quarters pound of crude carbonate of potash (pearlash), diluting the whole to 10 gallons, and lastly adding 10 ozs. of softsoap, dissolved in hot water, stirring vigorously to effect a complete mixture. As it is injurious to both clothes and skin, any old garments suffice during application, and the hands should be protected. It is best distributed on a very still day in the form of a mist-like spray, forced from a knapsack pump. A syringe can be used with a very fine nozzle, but occupies far more time, and wastes much material. The solution should rest on every part of the branches and twigs like dew, not run off them like rain. It destroys parasitic growths, and the eggs of most insects. In bad cases two sprayings may be needed, the second just as there are signs of bud-swelling. When once the trees are clean one spraying annually will keep them free from many destructive insect pests.

ROOT NOURISHMENT.—This is very important for assisting enfeebled trees. Different methods are resorted to. The quickest is liquid manure, applied at any time when it will sink into the ground when the soil is not dry. It can be given stronger, and with great benefit, during suitable weather in winter and spring than in the summer. Pouring liquid manure into *dry* soil is wasteful, and may be injurious. The soil is generally in the right condition when trees are swelling their buds.

Stable and farmyard drainage is good; failing this or sewerage, a solution of good guano, at the rate of an ounce to a gallon of water, is nourishing. According to analysis, Chinchas Peruvian Guano is the best in the market (advertised by the Anglo-Continental Company, 30, Mark Lane, London). Not less than 5 gallons of liquid should be poured into each square yard from the stem outwards beyond the spread of the branches for acting beneficially on stunted trees in impoverished ground.

FRESH SOIL.—This is of great value if brought within reach of the roots. A good method of effecting this is by making a number of deep and wide holes with a crowbar, 18 inches apart all over the ground, that the branches of a tree cover, then well pressing down in them fresh loam, containing a sixth part of wood ashes and one shovelful of basic slag to about fifty of soil. It ought to be just moist enough for compression. If liquid manure were poured in the holes prior to filling them with soil, the combination would be bound to do much good.

ROOT-PRUNING.—This is usually resorted to as the best of all methods for subduing the growth of over-luxuriant trees, but if rightly practised, may benefit the enfeebled. Cutting the roots of these near the stems, however, would lead to further enfeeblement. They must be cut some distance from them by digging out a wide trench 2 feet deep or more nearly as far as the branches spread, cutting smooth with a knife the ends of the spade-chopped roots from the under side upwards. Then by filling the trench with some fresh soil and a liberal amount of manure, with a sprinkling of basic slag, and any quantity of burnt and decayed vegetable refuse, pressing the whole down firmly, the emission of feeding roots would be incited and the growth of the trees consequently improved, as is the case through new roots taking possession of new soil in the holes above mentioned. If roots cannot be found where the circular trench is made, dig back till a goodly number are met with of the thickness of the finger to that of a stout walking stick, and treat as directed. This is best done when the leaves are falling in the autumn, but fresh soil may be given by the crowbar method at any time. It has proved highly beneficial to numbers of old trees.

No. 6 Orchard.—Soil too cold and strong. The larger trees, but not old, require cleansing; and some a little thinning. Young trees making Willow-like growth would be improved by carefully replanting as advised for orchard 4, adding fresh lighter soil, and mulching thickly in early summer, the manure to remain and decay. Let the grass be dug from round other young trees, adding fresh soil, containing lime or basic slag. Leave the surface exposed, for the sun to warm the soil, stirring it occasionally; then, on the approach of dry summer weather, spread on a covering of somewhat lumpy manure—not a close plaster. This is to prevent the soil cracking and drying near the surface, which causes the roots to strike downward for moisture in the cold sour subsoil, the resulting growth being then, however strong it may appear, of an essentially unhealthy and unfruitful character.—ADVISED.

IMPORTANCE OF CHANGE OF GROUND FOR PEAS.—Peas are a crop which do not succeed well year after year on the same soil. This is because nitrogen accumulates in the soil, and though plenty of haulm and leafage may be developed, the production of seed is not large.—S.

CHARACTER UNDER CANVAS.

1.—UNJUDICIAL JUDGES.

If the Prime Minister of Great Britain ever has glimpses of his personal greatness, they must fade when he visits a horticultural exhibition and finds his ineffectual fire paling under the glowing radiance of the unjudicial judge. It is true the statesman has the power of shaping the destinies of the world; he can control the movements of the most powerful fleet that ever sailed the seas; in the hollow of his hand lies the fate of millions of human beings; but—he cannot judge a brace of Cucumbers. Therefore the unjudicial judge looks down on him with delightful contempt, and relegates him to his proper place in the life of the nation.

It is given to most of us to have brief periods of ecstatic happiness. They are rare, they are fleeting, but they exist. Who seizes upon them so eagerly and extracts the last particle out of them so resolutely as the unjudicial judge? His days of pure delight are those on which he finds himself chosen, in preference to his rival over at the Grange, to judge at the summer show. Owing to a disappointment, a certain committee once found itself under the necessity of finding a judge at eighteen hours' notice. The secretary formed himself into a deputation, and visited a neighbouring gardener. The latter did not allow any false pride at being only chosen in an emergency to stand in the way of an eager acceptance. He took the schedule, marked his instructions, and showed the secretary over the flower garden. "Are you showing in the six Asters?" asked the newly appointed judge. "Yes," responded the secretary. Silently, but with a noble determination, the judge snipped off half a dozen of his best blooms. "Take 'em in your 'at," he whispered in tones of devoted friendship.

There are special moments when the unjudicial judge shines at his brightest. Take, for instance, his bearing when, after his duties are done and a substantial lunch has been disposed of, he saunters, much badged, into the show and surveys the scene of his labours with unctuous pride. There swoops down upon him an irritated exhibitor, who demands to know why a certain decision has been made. Is the unjudicial judge taken aback? Perhaps for a short space his confident bearing shows traces of a shock; but with a presence of mind worthy of the highest praise, he recovers himself, eyes the angry critic with calm benignity, and says, "T'was my partners; I didn't want 'em to do it, but they was two to one!" After a fairly lengthy experience of exhibitions, I have come to the conclusion that the greatest monument of incompetence this earth can boast is the mysterious "partner" of the unjudicial judge.

It is with a proper sense of humility that I speak of one particular occasion when I myself had been the erring "partner." The judging was done, the lunch was over, and I, book in pocket, retired to the shady side of a tent to pass the time before the prize-giving. The clatter of glasses, not less than the loquacious run of tongue, betrayed that it was the refreshment tent. While wrestling with a Meredithian epigram there fell upon my ear the voices of the judge with whom I had been associated and a stranger in a duologue that began fiercely and ended like the cooing of a dove.

"You a judge!" (this with ineffable contempt) "reckon you don't know a marra from a squash."

"T'was'n me, you fule, 't'was my partner."

There was a short but eloquent pause, during which a guilty sense of wrong-doing made short work of my mental peace, and then, in reply to another remark which I could not catch, the unjudicial judge said, in soft tones of amity, "Well, I doan't mind if I do; one bit of sugar and no lemon."

The cheerful magnanimity with which the unjudicial judge throws his partner to the wolves is not more impressive than the air of terrific superiority with which some members of the genus listen to the remarks of their fellow judges, and afterwards give the criticisms off as their own. Men of this stamp are known who, when invited to give an opinion as to the merit of an exhibit, wander off into particulars of domestic history, giving details of what they have at home, but "not allowed to show, you know," and other interesting information, all the while evading the point at issue. These gentlemen are invariably to be observed later in the day enlarging on the exhibits in loud and argumentative tones. There are plenty of persons who have never been known to give an opinion, or to make an independent decision, while the judicial work is going on, who are in universal demand as judges, solely from their copious and profound expression of other people's opinions when the duties of the day are done.

Fierce assertions of unswerving rectitude are not uncommon on the part of the unjudicial judge. It is true that there is usually no particular reason why they should be made, inasmuch as no charge of partiality is circulated. But this species is so full of the responsibilities of his position, that he runs over and emphasises every award with assurances that he is not to be got over. "No use a trying that with me," and so on. It was with a judge of this tremendous integrity that I once became involved in a tedious argument about a bunch of white Turnips. Those which he wanted to put first, I wanted to put third. After striving unavailingly to get me to agree with him, the unjudicial judge drew me aside, with an air of touching reproach, and said in my ear, "Look here, now; if you'd got a boy Sammy—"

I stared in amazement. "A wha—at?"

"You haven't, eh! But I have. Do you see?"

Gently, insinuatingly, the righteous judge scribbled "first" on Sammy's card, and led me away.—W. PEA.

PRUNING ROSES.

ALTHOUGH such a very mild season, I do not think our Roses more forward than usual, and certainly would not prune earlier than after winters of ordinary severity. It is not early growth which we want upon Roses, but breaks from healthy eyes, and these made sufficiently late to insure a greater chance of quick growth, unchecked by the late spring frosts which so often ruin early and promising new wood.

With a view to making the present article upon this important part of Rose culture more plain and simple, I have taken a few rough sketches of

FIG. 44. TWO-YEAR-OLD TEA ROSE. FIG. 45.—H.T. CAROLINE TESTOUT

types of plants growing in my garden, and which I shall prune upon the lines indicated in the illustrations. It does not matter whether it be Hybrid Perpetuals, Teas, Hybrid Teas, or any of the other classes, our Roses of similar growth to those described need much the same treatment.

Fig. 44 represents a two-year old plant of a Tea Rose of an erect growing variety, which flowers freely from almost every shoot, and which may be chosen as a type of such as Anna Olivier, Catherine Mermet, Madame Lambard, and others of the similar habit. The shoots from the base, marked *a*, *b*, and *c*, are soft and pithy, although they carried good blooms late in the season. From 6 to 12 inches from the base of these there is a sound eye or bud, and the wood will be cut back to this point. The remainder of the growth will be cut back, as shown by the cross marks. Most of the wood above these marks is inclined to be soft, and will, under any circumstances, be cut back to a sound and well-ripened eye.

Unless we prune this class of Rose rather hard we get a succession of new growths from the top eye, which, on account of the erect habit, soon make a thin and pyramidal plant, instead of the desired bush of more compact form. We have much the same habit in Merveille de Lyon and

FIG. 46.—H.P. DUKE OF EDINBURGH.

Baroness Rothschild from among the Hybrid Perpetuals, although more robust. These varieties very seldom carry soft and unripened wood, but

owing to the same erect habit, I would cut them back almost as hard as shown in the cut.

An old and fairly strong plant of Comtesse de Nadaillac, Sunset, Perle des Jardins, Souvenir d'Elise Vardon, and a few more, will often produce a succession of stout shoots from the base, as marked *a*, *b*, and *c* in fig. 44. Instead of cutting these down so hard I would only prune back to the first sound eye. Nor should any well matured wood of these be cut away except to thin out the growth where rather crowded and dense. Horace Vernet, Duchess of Bedford, Louis Van Houtte, and similarly habited Hybrid Perpetuals, grow in the same erratic fashion in most gardens, and need the same style of pruning. It is a general rule to prune a Rose hard if a weak grower, and very slightly when of extra vigorous habit, but in the few last instances I would leave almost all of the sound eyes.

Fig. 45 is a plant of Hybrid Tea Caroline Testout, also two years old. Here we have a Rose of entirely different habit, one which makes a succession of growths all through the season, and, although not so spreading as some, forms a much wider bush than in fig. 44. My plant is carrying the same shoots as shown. The three portions of dead wood will be cut back to a sound eye, and the remainder shortened and thinned according to the cross marks. This will result in a compact bush, which in all probability will be twice its present size next autumn. Much of the wood cut away in this case will be thoroughly sound and ripe, but by pruning, as illustrated, we get a better bush, flowers of better quality, and quite as many of them.

There are many varieties with a somewhat similar habit to Caroline Testout. Mrs. Bosanquet, Goubault, Madame Falcot, Madame Willermoz, Kaiserin Augusta Victoria, Rosa Mundi, Souvenir de Paul Neyron, Marie Van Houtte, Francisca Kruger, and Alfred Colomb may be cited as examples needing the same pruning. We also have Dupuy Jamain, Général Jacqueminot, Mrs. John Laing, Camille Bernardin, Charles Lefebvre, Fisher Holmes, Maurice Bernardin, Prince Camille de Rohan, and several other varieties which range between figs. 45 and 46 as regards habit and vigour of growth.

Fig. 46 is a two-years-old Duke of Edinburgh. The cross lines show where to prune this if a bush plant is wanted; and the four dotted lines, where it should be pruned if intended for pegging down, as exemplified in fig. 47. For this purpose the long sucker-like rods, *a*, *b*, *c*, and *d*, will only be pruned back a few inches from the point, and then secured in a horizontal position, when they will flower from almost every well-ripened eye. The vigorous Teas, Hybrid Teas, and Hybrid Perpetuals may be treated similarly, following one or other of these systems according to

FIG. 47.—H.P. MADAME GABRIEL LUIZET.

whether a fairly well-shaped bush, or a larger quantity of flowers are needed. Those varieties named as between the types of figs. 45 and 46 should be pruned midway between the two illustrations.

Fig. 47 represents a Madame Gabriel Luizet that was pegged down last year. The side shoots have flowered, and should be cut off at the cross marks. It generally happens that the wood upon these layered shoots is so ripe and sound that many are tempted to prune, such as shown by the dotted lines (figs. 46 and 47), but if we do so we get a less number of flowers, and these of inferior quality to what would be the case if the long shoots *a*, *b*, *c*, and *d* were pegged down, and the older wood cut out entirely. There are many of our very vigorous growing Teas, Noisettes, Hybrid Perpetuals, and others, which give a far better display when pegged down in this way than grown as an ordinary bush.

When these same varieties are upon a wall or fence, it is better to save as much as possible of the longest and most vigorous growths, making room for these by cutting out older wood.

Standards of the same classes or types of Roses need the same style of pruning, the long rods in figs. 46 and 47 being allowed to droop over with the weight of growth and blossom. As a rule the Mosses, Cabbage, and Gallica Roses are best when pruned upon rather harder lines than recommended in fig. 44. The Scotch and Japanese Briars, also the Polyanthas, merely require the points of dead wood removed.

Fig. 48 shows a Rose planted in the autumn, one of many thousands that will soon need pruning. The upper buds are elongating considerably, as is the case also with the older plants above referred to, though the advancing growths are not depicted. As a rule the longer in reason these

basal buds remain dormant the safer the growths which issue from them are against the accident of frost, and the earlier the pruning the sooner those buds are pushed into danger. That is why many cautious persons defer the pruning till March is well advanced, and then the stems of the young Roses are cut down to the marks or lower, even at the risk of some "bleeding," from which plants unchecked by frost soon seem to recover.

So far as the best time for pruning Roses is concerned quite as much depends upon the position as the season. In low and moist situations we suffer from late spring frosts much more than upon a high and fairly dry soil. Nor do the plants in the latter case make such precocious growth as when in a warmer and more sheltered spot.

Make it a point to cut back to a sound eye, have this facing away from the centre of the plant where possible, and cut the wood back close to the terminal eye or bud.

The rambling Roses, such as Ayrshires, Boursaults, Evergreens and Hybrids of similar growth, merely need some of the older wood thinned out and last year's shoots left their entire length.—PRACTICE.

FIG. 48.—PRUNING NEWLY PLANTED ROSE.

ANOTHER MIXTURE.

THE STRAWBERRY AS AN ANNUAL.

WHERE there is no lack of labour in gardens, or where a gardener is fairly well handed, the question of the cultivation of the Strawberry as an annual will gradually resolve itself into a general practice. There was a time when plantations of Strawberries were kept going for years, producing average crops of undersized fruit, admirably suited for preserving, and nothing else; but in the present go-ahead days a gardener is expected to grow them as large as possible. Nothing short of a fruit an ounce weight seems to satisfy some employers. That this can be accomplished is evident by various reports last year of Strawberries scaling 3 ozs. This weight seems incredible even in this age of gigantic productions, and, if correct, the fruit would require more than the proverbial "two bites" to dispose of it. Annual planting has much to recommend it, especially with certain varieties, such as King of the Earlies, Royal Sovereign, President, Scarlet Queen, and La Grosse Snerée, with Vicomtesse Hericart de Thury, Keen's Seedling, Grove End Scarlet, and others, that are suitable for preserving; these would stand two or three years. The secret of good culture rests in layering early, from maiden plants if possible, planting in firm, rich, warm borders or beds in July or August, well mulching with half-decayed manure, watering the plants in dry times, and well bedding down with litter in early winter, having previously kept down all weeds and removed runners.

HATCHING EARWIGS.

Recently I had occasion to have prepared several pits for early Potatoes and Carrots. The material used was ordinary stable manure and leaves, the latter predominating, which, after a few turnings, was put in, made firm, and soiled. Chancing to lift one of the lights during a sunny day, I was astonished to see hundreds of baby earwigs perambulating the surface of the warm soil, evidently stretching their limbs and developing their bodies in order to be in better training for the Peaches and Apricots when ripe, where they will without doubt migrate. Is it correct the female broods her eggs and hatches them, or has the artificial heat acted in the way of an incubator, and brought forth this very undesirable family? They were present in all stages of early life, but I did not see any old ones present. There are still incredulous folk who will not be convinced that earwigs have the power to fly. That they can, and do in numbers, I have testified on various occasions. The best traps I find are hollow tubes of dry Hemlock, or anything of that kind, placed about the trees, blowing the pests out every morning into a wide-mouthed bottle, with a little paraffin or hot water in. I have had the tubes completely blocked at times with a huddling mass of full-blown earwigs after a night's gorging and feasting.

CHIMONANTHUS FRAGRANS.

This is a very sweet-scented desirable shrub, flowering as it does in the early months of the year before the leaves make their appearance. We have it against a west wall. It appears to flower in the axils of the previous year's growth, rendering it most necessary to be pruned after flowering to induce well-grown shoots, which, if ripened, should produce the maximum of flowers. It thrives best in good light soil, and is benefited during the growing season with supplies of liquid manure. If a few of the flowers only are cut they prove sufficient to permeate a room with delicious fragrance. It has a similar scent to Daphne indica, and its time of flowering corresponds. We are not too well off for such shrubs as the Chimonanthus, the flowers of which are so welcome early in the year by their sweet perfume.—GEO. DYKE, *Stubton Gardens*.

NEW FRENCH CHRYSANTHEMUMS.

"OBSERVER" (page 172) is, of course, not aware that my article on this subject was written a long time before its appearance in print, possibly being crowded out by more pressing matter. If Mdlle. Lucie Faure and Madame Ferlat had been authoritatively pronounced as incurved, I should have conformed to that ruling; but when novelties are seen for the first season, individual writers can only form their own impression of them from such examples as come under their notice. "Observer" may, no doubt, consider the task an easy one to decide for himself whether a novelty is incurved or Japanese incurved; but I notice that even my friend Mr Molyneux protests against the free and easy way in which some of the "mongrels" are being included in the true incurved section, so that difference of opinion would perhaps have been a better word to use than misrepresentation. "Observer" carries his criticism a little farther, and objects to some of the descriptive terms I employ. If "Observer" does not know the meaning of "distinct novelty," I can only say that Madame Ed. Roger is a novelty because it is new; that it is distinct because it is green, and unlike any other novelty.—C. H. P.

BELFAST SHOW REFLECTIONS.

AS regards the variety shown by Mr. Mease as Yellow Madame Carnot at Belfast, Mr. Brock refers me to Mr. Molyneux's notes on new varieties in your issue for December 9th. Allow me to inform him that Mr. Molyneux was one of the judges who passed Mr. Mease's fine bloom at the Royal Aquarium labelled as Yellow Madame Carnot, and Mr. Molyneux's remarks on new varieties were not made till after the shows, when he would have had every opportunity of thoroughly examining all the different sports in question. I well remember when Charles Davis was brought before the Floral Committee of the N.C.S. by various exhibitors, the colour variations were far more distinct than any forms of yellow sports of Madame Carnot. Mr. Mease, no doubt, made himself thoroughly acquainted with the Belfast schedule before sending such a distance, and surely such an old hand at exhibiting would not knowingly risk staging a variety that was not in commerce. I always thought it is a mistake to confine exhibitors to varieties in commerce. It is perplexing both to exhibitors and judges, and as far as I can see answers no good purpose. Respecting the cardboard used, I said nothing about its being legitimate. I thought I made it clear that if the cardboard were removed the exhibitor would have been placed in the same position on the merits of his blooms alone. I can assure Mr. Brock he need not apologise, at least to me; my feelings are not wounded in the slightest. I rather delight in fair criticism.—E. BECKETT, *Aldenham House Gardens*.

PERHAPS a little explanation from me may put the matter *re* Primrose Madame Carnot a little more satisfactorily. I was the introducer of G. J. Warren, and Mr. Jones introduced Yellow Madame Carnot, which to all appearances were the same. I had also heard of or seen six other yellow sports from various places, one of which was at Box Hill, and which Mr. Mease was growing. These various sports were all supposed to have been the same in colour, and although Mr. Mease had the champion flower in the November show of the N.C.S., no one would have known whether it was any different from G. J. Warren in the bad light. Indeed, I believe Mr. Mease fully thought then, as I did, that they were the same, and sent his blooms to Belfast honestly thinking he was acting according to the schedule.

Not being an exhibitor I had not noticed the regulation that "All blooms must be already in commerce." As I was assisting Mr. Mease's man in naming his blooms the good light enabled me to see the bloom in question was not so deep in colour as G. J. Warren, but a primrose colour. I, therefore, said that was not G. J. Warren (syn., Yellow Madame Carnot), and I advised that it be simply described "Primrose Carnot," quite ignorant of the conditions. Moreover, had these conditions been in the mind of Mr. Mease's assistant he had plenty of spare blooms, and could easily have rectified the matter, and he would then have held exactly the same position. I can fully sympathise with Mr. Beckett, and do not see how he could have done otherwise than he did under the circumstances.

As I fear that I was the cause of all the trouble which has arisen by the suggestion I innocently made, I think the above explanation is due to all concerned. I am quite sure that Mr. Mease would not attempt to evade any conditions, and I am also sure that Mr. Beckett felt the difficulty of the position in which he was placed and did what he thought was right. I have absolutely no personal feeling in the matter. I think Mr. Brock was justified in bringing the matter forward, and should like to see him defeat all comers next autumn.—W. WELLS.

[We think the explanation of the matter in dispute is as clear as it can be made. The "bad light" in the Aquarium was quite inadequate for detecting different shades of yellow, and we fully believe that all who have been personally interested in this case acted in the best of good faith. Mr. Brock was justified in bringing the matter forward. We think when large sums of money can be provided for sensational prizes, two judges should be engaged as security against accidents, and when this is not

done we are inclined to regard the show authorities largely responsible for what may happen of the nature indicated. After no small experience with a goodly number of highly capable and deservedly trusted judges, we have not discovered the prodigy of infallibility.]

DECLINE OF INCURVED CHRYSANTHEMUMS.

I DO not think there is one person of experience who will attempt to refute the above heading. Visitors to the autumn exhibitions in various parts of the country find a steady decline in this type of the autumn queen. Not only a backward tendency in popularity with visitors, but a gradual falling off in the quality of the blooms. No doubt there are strong reasons for this rapid decline in the true Chinese or incurved Chrysanthemum. Writers, cultivators, and visitors will draw their own conclusions as to the cause. Having perhaps as much opportunity as most persons who are interested in this section, owing to my extensive tours annually to the principal exhibitions, I have decided in my own mind what are some of the causes of decline in this section. Although the exhibition table is a good basis to found a reason upon, it cannot be urged that it is the end of all that appertains to Chrysanthemums. Many persons who object to exhibiting pay annual visits to the autumn meetings to view the productions of others, and may be to pick up an occasional wrinkle or two.

I do not purpose dealing with this subject purely from an exhibitor's point of view, but rather in a general way. No one, however, will doubt that to see the finest specimens of incurved Chrysanthemums we must visit the exhibition table. Although some of the finest blooms as grown are often seen on purely decorative plants, yet the finishing touches are usually seen upon the exhibition table. It cannot be urged that any decline is due to a want of recognition in the various prize schedules. In the palmiest days of incurved Chrysanthemums the prizes offered were decidedly inferior in value to what they are at the present time. It is not an uncommon occurrence now to find a class for twenty-four blooms, these not distinct, for which the handsome sum of £10 and a silver cup are offered as the first prize. Exhibitors of experience know well how much easier it is to fill a class where half a dozen duplicate blooms are allowed as compared to the distinct requirements of classes. The decline then is not due to want of encouragement.

If we desire to seek for reasons, from an exhibition point of view, we must recognise the weakened constitution of certain varieties or families. Whatever may be the cause of this, it cannot be doubted that there is this deterioration in stamina. Take, for instance, that group known as the "Tecks." Can it be argued that a single bloom of any one of the seven varieties comprised in the family is seen nowadays that in any way resembles those grown half a dozen years since? He would indeed be a bold man who says yes. This once valued type has been in existence thirty years, being introduced by Pethers 1868, and four years after saw the first sport in the form of that charming rose pink flower Hero of Stoke Newington. As showing the value of this variety for exhibition, it was almost invariably found in the back row in the strongest competition. I mention this to show the difference existing a few years as compared with the present day. Nowadays it is difficult to find this variety in a stand, which proves conclusively its decadence as an exhibition flower. Even Princess of Wales is now only a shadow of its former self. No variety has taken or assisted to secure so many prizes as this when staged in what is known at an undressed condition. The natural form, beauty of floret and solidity of the whole bloom of a fully-developed "Princess," was indeed something to admire to a lover of incurved Chrysanthemums.

But from an exhibition point of view the greatest declination is in the Queen of England and its light offspring. The original of this group was introduced by Salter as long ago as 1847. Twenty years ago it was no unusual sight to see plants 10 feet high, while now the difficulty appears to be to get them half that height. Some cultivators may urge that this is desirable. I have, however, seen the finest of the blooms that have been produced during the period named, and not infrequently the plants bearing them also, and if it were an easy matter to obtain exhibition blooms from tall plants in days gone by, and it is quite the reverse at the present time from dwarf plants, the conclusions to be drawn are too obvious to need comment. Can cultivators induce their plants to grow as strong or as tall as they would wish? If they can and then do not produce representative blooms, what is the reason? To what source but that of deteriorated constitution can we attribute the decline of varieties that are well known to be of the first-class?

Counteracting influences are advocated, such as planting out and growing the plants for a couple of years in poor soil. The idea is that the constitution of the plants has been weakened by feeding and other unnatural methods. I confess I regard such opinions as those of pure theorists. It is very well for a person to give it as his opinion, based purely upon supposition that the above remedy is the all-saving ground for success; but I for one do not accept it, for the simple reason that I have put such proposals and many others to the test, in the hope of securing creditable examples of the various members of the "Queen" family. Repeated experiments of changing stock, propagating on the coolest of methods that a cold frame will admit, in the hope that the slowest of the initiatory growth would lay a foundation for a more substantial superstructure, have all failed. Twenty years since I saw better blooms of the "Queen" family growing against a south wall in the near neighbourhood of Liverpool than three parts of those seen on the exhibition table last season. How do theorists account for this? Many exhibitors of the present day do not take the same personal interest in the growth of the plants or the preparation of the blooms for showing as was the case a decade or two ago. Too much of the work

is left to the inexperienced hands of the journeyman, whose duty it is to grow the Chrysanthemums from beginning to end. Nowadays there are exhibitors who expect to engage a youth capable of cultivating Chrysanthemums up to the best exhibition form. Need we wonder, then, if there is decline in some of the sections, especially in that which is by all admitted to be the more difficult to produce?

When summing up the causes of the decline of this once popular flower it is well to look all the points sternly in the face with a view to remedy. The introduction of new varieties of doubtful character is all in favour of a decline in interest in the section. At least a dozen leading sorts might be named to which exception can easily be taken. There is too much inconsistency in some varieties ever to make them sufficiently reliable as a means of improving those whose position they now occupy. Many growers rely so much on mere size instead of recognising quality as a first step towards perfection. It does not require a wide stretch of imagination to compare some of the present day blossoms with old Fingal, for instance, which I regarded little better than a hedgehog in appearance.

I now come to the cause of what I term the general decline of the section as exhibition flowers for decorative purposes and as a type of the autumn queen. The many attractions offered by the more recently introduced Japanese section have done much to elbow their more forward rivals out of public favour. I am not surprised at this change. What an immense advantage is found in the use of Japanese Chrysanthemums for purely decorative purposes as compared to other sections generally, but especially to the incurved class. The points so overwhelming in Japanese are so well known that there is little need to rename them. The loose feathery appearance of the blooms, coupled with such infinite variety of colour, at once places them a long way ahead of their opponents. Worthy of emphasis, too, is the strength of the peduncle of nearly all Japanese as compared with many incurved sorts. Never was there a better opportunity of comparing the value of the two sections as decorative objects than that afforded by the competition for the valuable prizes offered at the last autumn exhibition in Edinburgh in the class for a certain number of blooms on long stems staged in vases. One exhibitor staged a mixture of incurved and Japanese. The former looked too "lumpy" to be pleasing, while representative specimens of the latter provided many enviable features.

If we compare a stated number of plants grown on what is known as the decorative system—viz., plants to produce blooms in quantity—then the effect is still worse, as the peduncles are more weakened in some varieties, while the colour diminishes perceptibly in certain sorts. To sum up the whole case in as short a sentence as possible, the incurved Chrysanthemum is irretrievably on the decline.—E. MOLYNEUX.

"THE CHEMISTRY OF THE GARDEN." *

THIS is one of those neat little pocket primers which the publishing firm of Macmillan & Co. have of late given to the world with such good results. Like its red-covered predecessors, its cost is the ordinary shilling, and again like to those it is exceedingly clear, and, as it ought to be, almost elementary in its teachings. The author, Mr. H. H. Cousins, who is one of the professors of the South-Eastern Agricultural College, Wye, Kent, where horticulture is also keenly studied, seems to have been touched by a complaint recently made in the *Journal of Horticulture*, that no such little cheap elementary book as he has now furnished was in publication. Certainly he seems to have filled the void with remarkable success.

Naturally the primary text of the book is manuring, or plant feeding; but the author has wisely, though briefly, opened with a chapter on "Plants: Their Composition, and How They Grow;" because it is indispensable that the student reader, be he professional gardener or amateur, should fully understand a plant's requirements ere he sets about feeding it. This little excursion into plant physiology is accompanied with language of the most easily understood character, being devoid of scientific technicalities. It is a short excursion, which should whet the minds of all readers for a much longer one, into a theme that should be for all gardeners entrancing.

Next we find the air, and the part it plays in plant production, dealt with, and there again valuable information afforded, because many cultivators, ignoring the exceeding importance of ample light and air to plants, neglect the furnishing of these elements, whilst they squander money liberally in purchasing good or bad root foods. Mr. Cousins briefly refers to the recognised capacity of leguminous plants to gather nitrogen from the atmosphere through the agency of root nodules—a matter of exceeding interest to know; but the cultivator also recognises the fact that such faculty is greatly helped when nitrogen, associated with other foods, is applied to the soil, and the plants, not crowded, have ample light and air. Ammonia, so often found floating in the air in association with manure heaps, is so much waste to the owner, because it should be buried in the soil. Not infrequently falling rains wash it into the soils of others. Still olfactory evidence of its presence should warn all concerned that waste is proceeding.

A chapter is well devoted to soils, the diverse characters of which are admirably described. Naturally it is important that the composition of these should be generally understood by the gardener, if only in an elementary way. The author regards the presence of chalk in the soil as a most valuable ingredient, but he goes rather far when he asserts that

it is an absolute essential to fertility, as the alluvial deposits of the Thames valley, for instance, are very innocent of chalk, yet are exceedingly fertile. All the same, an occasional dressing of chalk is good, but in many localities the material has to be furnished by means of occasional lime dressings.

Very important indeed are the remarks as to drainage and its bearing on soil temperature. This is a simple matter, but all the same too little understood or regarded. The presence of water choking air passages signifies cold, because it is so long before the moisture can be evaporated and warm air find access. Gardeners of all classes so fond of dabbling heavy mulchings of manure in the winter over the roots of fruit trees, Roses, or myriads of other things to protect from frost—a problematical benefit if the manure be gross and wet—should always remove these dressings in the spring that the sun may as early as possible warm the soil, and thus give the roots active and healthy stimulus. Summer mulchings applied in May or June after the soil has become well warmed are then most valuable.

In a succeeding chapter the author asks the pertinent question as to soils—"What is fertility?" and proceeds to describe it, and how estimated and created. He is here a little hard upon some of the nostrums put into commerce with such glib recommendations by well paid or interested persons, and to which special reference is not here needed. The value of experimenting with various manures, true and false, is urged; and, indeed, whilst in a sense few may find the product pecuniarily profitable, yet very much valuable experience would result. It is obvious, however, that let these experiments be conducted by the most learned of scientists, or otherwise, they have no value whatever if tainted by self-interest. From that element we are sure the Agricultural College at Wye is entirely free.

Mr. Cousins evidently regards the ash or burnt produce of plants theory, as bearing on their food needs, as fallacious. It is rather hard to have comfortable theories of this nature so roughly knocked on the head, because the student naturally feels that for his belief in these matters it is difficult to find a resting place. All the same, it is the duty, and should be the mission of scientists as they become through experience wiser, to knock down old and firmly cherished beliefs of still older scientists without compunction so soon as found to be fallacious. Eventually the chapter in our little primer on garden chemistry leads up to the heart of the matter—manuring; and here is opened a subject wide enough indeed, and abounding with interest, but yet treated in so simple and practical a way that he who runs almost may read and understand. Animal, green, and artificial manures, their compositions and adaptabilities, are very fully dealt with; and as if not satisfied with conquering that matter, Mr. Cousins adds a few chapters on garden enemies, and the way in which, with the aid of chemical solutions or compounds, these may be kept in check or exterminated.

All these things are, however, for the reader, and that should be every gardener, young or old, professional or amateur, in the kingdom. To young gardeners especially the book will be of exceeding value, because it will furnish them with abundant matter for thought as well as most important information. Candidates for the Royal Horticultural examinations will find it a capital text book, and it is in some respects more clear and up to date than are the rather costly books by assumed superior authorities so often recommended. I notice with special pleasure that the author in relation to spraying fruit trees and Potatoes recommends parish councils to obtain spraying outfits for local use. I have often advised this, and gone farther and urged that local authorities should have compulsory powers to use these in any place so soon as evidence of need for their employment was furnished.

This instructive and essentially useful primer has been edited by Mr. J. Wright, whose aid the author generously acknowledges, and an equal blending of science with practice in gardening is not, so far as I know, elsewhere to be found at the price.—A. D.

KEW BULLETIN.—The November issue of this publication, which has just come to hand, is almost wholly devoted to a report of the proceedings of the West Indian Royal Commission. The inquiry has apparently been an exhaustive one, and has evidently been conducted with care. The Commissioners were Sir H. W. Norman, Sir Edward Grey, Bart., and Sir David Barbour, K.C.S.I., who were accompanied by D. Morris, Esq., D.Sc., C.M.G., Assistant Director of Kew Gardens as botanical adviser. The concluding observations of the Commissioners are:—"We cannot close our report without expressing our strong sympathy with the planters, who have struggled against very adverse circumstances to maintain the sugar industry, and with the very numerous persons who depend directly or indirectly upon that industry, and have severely suffered from its decay. Among the latter we would include not only the labourers, but many of different races and a higher social class, who, as clerks, overseers, artisans, tradesmen, or in professional vocations, have been impoverished by the depression in sugar. Our own task has been of a discouraging nature. Our duty has been to inquire into the condition of a depressed and failing industry, and to consider if any means are possible for restoring and maintaining the prosperity of those colonies that depend upon it, and, in any case, to suggest the establishment of other industries which might supplement the cultivation of sugar cane, and, in case of need, provide means of subsistence for the people. Our conclusions will, no doubt, disappoint many who have looked for some immediate and substantial relief, but, with the most sincere wish to do all in our power to help the West Indian community, we have not felt ourselves able to make other recommendations than those which we now humbly submit for your Majesty's gracious consideration."

* Macmillan & Co., Ltd., St. Martin's Street, London, W.C.

HOLLYHOCKS FROM SEED.

IN years gone by, before these noblest of old English flowers were stricken by the fungus, *Puccinia malvacearum*, they were seen in practically all gardens, and never since then have our gardens and pleasure grounds been furnished in such an imposing manner. Huge clumps of towering spikes, bearing massive flowers in pure, rich, and varied colours, were seen almost everywhere, while long lines, either flanking walks or as a background to borders, resembled floral walls or pillars of beauty.

In the pre-disease days choice varieties were increased by cuttings or grafting, and named collections were grown in gardens in various parts of the kingdom. They were also in strong force at flower shows, the spikes being some 2 feet long, the tops having been removed and the buds thinned for affording space for the development of handsome blooms. These massive spikes were inserted in pots of damp sand, and hundreds of them often placed in competition.

FIG. 49.—DOUBLE HOLLYHOCKS.

Blooms were also in proportionate numbers displayed in stands in the same way as are Chrysanthemums, Dahlias, and Roses. If such Hollyhock displays were seen now they would cause something like a sensation.

Named collections exist still, particularly in the north, where the disease does not appear to have been so virulent as in the southern and midland counties. Whether it might have been subdued if Bordeaux mixture had been discovered and systematically applied in the early days of the fungus visitation can never be known; but what is known is that it swept like a scourge over the country and practically exterminated the grand race of double Hollyhocks. It was noticeable, however, that where clumps of the old rosy single forms were established, as in cottage gardens, that these to a large extent escaped, if not injury, at least destruction. Whether this was the result of innate hardiness, or through being left to "grow themselves" in poor soil, is not known; but what is known is this—gardens have presented a more or less "empty" appearance since the stately and massive double Hollyhocks were driven away.

Plants were also raised from seeds in those days, and the seedlings in turn became infested. In all probability the disease spores were sown with the seed, and it is not easy to imagine "clean" seed being obtainable. Happily the case is different now. Plants may be seen

once more, and in steadily increasing numbers yearly, raised from seed and only allowed to flower once, as biennials, which are free from the destructive parasite, and the seed from such plants is "clean." For decorative purposes, then, Hollyhocks are again possible in our gardens by raising plants yearly from such seed and treating them as annuals or biennials, and this is the cheapest of all methods of providing a display.

It may, perhaps, be a "new notion" to some young men to suggest growing Hollyhocks as annuals, as they may not have seen them raised and flowered the same year; but this has been so with thousands, and they are as worthy of being so treated—i.e., flowered and destroyed—as are the perennial blue Lobelias. In not a few large gardens in the kingdom Hollyhocks or other flowers are even more acceptable in the autumn than in the summer for greeting the home-coming of "the family" after a few months of absence.

By sowing Hollyhock seed in January, or even perhaps at the present time, very thinly in gentle warmth; growing the seedlings in a very light position for keeping them sturdy; transplanting them 3 inches asunder in boxes, still maintaining sturdy growth; then when they touch each other transferring them to 5-inch pots, affording the plants gentle warmth for a time and much light; eventually removing them to frames, they will, under good cultural attention, be stout and strong by the time the weather is mild enough for planting them in the open, without any material risk of checks to growth ensuing. In the absence of such checks, and in good, deep soil, splendid plants and noble spikes of flowers will be enjoyed towards the end of August and throughout September. If the roots are subsequently dug up and reduced to ashes the plants will have begun and ended their career in one season, or in other words treated as annuals.

For flowering much earlier Hollyhocks must be treated as biennials, which is the easier way. In June sow the seeds thinly in drills a foot apart in the open garden as if sowing Parsnip seed in March. Thin out quickly if necessary to prevent the least crowding. When large enough transplant them 18 inches asunder in an open position, as if they were so many Strawberries, and run the hoe between them frequently. These plants will probably stand the winter, and may be carefully lifted and planted in spring where they are desired to flower, but it is advisable to establish a number in pots in October, eventually plunging these over the rims in ashes in a cold frame for passing the winter. By the exercise of sound judgment in watering and ventilating, also removing decaying parts, these plants will be in the best of condition for planting early in April, or whenever the ground and weather may be suitable for the work being done. They will flower grandly in the summer.

Single Hollyhocks are now represented in so many colours that they are really very beautiful and highly worthy of cultivation in positions where tall flowering plants are required; but doubles are still the favourites, and these may be grown from seed, and used to be grown in thousands of gardens, quite equal to those represented in the photographic illustration kindly furnished by request of the writer (who has had many similar displays), by Messrs. Sutton & Sons of Reading. Hollyhocks have been above alluded to as "old English Flowers." *Althæa rosea*, the originator of our varieties, is said to have come from China in 1573. John Parkinson, in 1629, records that many single and double varieties of Hollyhocks were then called "English Flowers," as "having been cultivated in this country for a very long time." Evidently the old florists sought for and obtained improvements soon after the arrival of the original introduction. Let us have more of these stately flowers in our gardens again.—AN OLD GROWER.

THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual general meeting will take place at the Caledonian Hotel, Adelphi Terrace, Strand, W.C., on Monday, March 14th, 1898, at 8 P.M. A special general meeting will follow, to take into consideration the advisability of altering the following rules, viz.:—Rule 8.—Alteration on page 9, line 8 from the top, instead of "£20" read "£30." Rule 14.—Page 11, line 10 from the bottom, after the words "lower scale" add the words, "with the privilege of increasing this to." Rule 14.—Page 12, line 14 from the top, the word "successive," after "twenty-six," be struck out. New rule, *re* Convalescent Fund, to follow rule 18, and to be called rule 18A, being headed—"Voluntary Convalescent Fund.—The object of this fund is to give members a change of air during convalescence. The Committee of Management to have power to relieve members of this Society from this voluntary fund as they may deem advisable. All cases must be recommended by a duly qualified medical practitioner."

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—MARCH 8TH.

THE meeting on Tuesday was one of the best early March meetings that have been held in the Drill Hall. Not only was there an extensive display of general plants and flowers, but the quality was very high, while a choicer collection of Orchids has seldom been seen.

FRUIT COMMITTEE.—Present: T. F. Rivers, Esq. (in the chair); with Rev. W. Wilks, and Messrs. G. Bunyard, A. H. Pearson, J. H. Veitch, G. W. Cummins, A. F. Barron, T. J. Saltmarsh, W. Poupart, J. Willard, G. Reynolds, T. Fife, J. Smith, H. Balderson, G. Wythes, W. Bates, W. J. Empson, C. Herrin, A. Dean, and J. Wright.

As will be seen there was a good attendance of members, but their duties were somewhat light.

Mr. Owen Thomas sent magnificent samples of his *Cucumber Every Day*, fruits uniform in shape, dark green, and attractive. They were cut from plants raised since Christmas. The high honour of a first-class certificate was awarded without a dissentient vote.

Mr. G. Wythes sent tubers of his new Artichoke Syon Long Red, tubers nearly a foot long, and 1½ inch in diameter. To be grown and cooked with other varieties at Chiswick. Mr. Wythes also sent fine bundles of Asparagus from outside beds, advanced and blanched with leaves. A cultural commendation was deservedly awarded.

Mr. W. J. Empson, gardener to Mrs. Wingfield, exhibited twenty dishes of well kept Apples, also very large Uvedale's St. Germain Pears. Prominent in the collection was a new local Apple, apparently intermediate between Beauty of Kent and Catshead—no doubt a very serviceable cooking Apple. A silver medal was awarded.

Mr. R. Bullock, gardener to C. P. Scrold, Esq., Taplow Hill, sent eight very good dishes of dessert Apples, for which a bronze medal was awarded.

Messrs. H. Lane & Son sent a large basket of handsome Lane's Prince Albert Apples; and Messrs. James Veitch & Sons, Limited, exhibited a pile of beautifully variegated Kale (vote of thanks).

Prizes for Flavour.—The first prize for a dish of Apples went to Cox's Orange Pippin as shown by Mr. Bullock, gardener to C. P. Scrold, Esq., Taplow Hill. The fruits were in superb condition. Mr. C. J. Salter came second with an excellent dish of Bess Pool. Mr. Maher, gardener to A. Waterhouse, Esq., Yattendon Court, was the only exhibitor of Pears, and received the second prize. The variety was Bergamotte Espere.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, J. Laing, H. B. May, R. Dean, G. Stevens, W. Howe, J. E. McLeod, T. Peed, J. Jennings, C. J. Salter, H. S. Leonard, W. Bain, J. D. Pawle, J. Fraser (Kew), D. B. Crane, C. Jeffries, T. W. Sanders, C. E. Shea, H. J. Jones, E. Beckett, E. T. Cook, G. Gordon, G. Paul, G. H. Engleheart, H. Turner, C. Blick, J. W. Barr, H. J. Cutbush, and J. Hudson.

The group of Camellias from Messrs. W. Paul & Son, Waltham Cross, which occupied one corner of the hall, was very effective. As is customary with the Waltham Cross plants, they were clean and healthy, and producing shapely flowers of excellent substance. A few of the most effective were Marchioness of Exeter, Madame Cochet, Mathotiana, fimbriata, C. H. Hovey, Double White, conspicua, and Ninfa Egeria. In addition to the plants, there were several boxes of cut blooms. Mr. T. S. Ware, Tottenham, sent a collection of Narcissi in pots, comprising most of the leading earlier flowering varieties. Besides these, there were Chionodoxas, Saxifragas, Primulas, Muscaris, and many others of equal interest. Messrs. Barr & Son, Covent Garden, sent a collection of Hellebores, Chionodoxas, Crocuses, Anemones, and Narcissi, which, if rather small, was very interesting.

Messrs. Peed & Son, Roupell Park Nurseries, sent a group of miscellaneous flowering plants. Clivias in variety were splendidly represented, as were Azaleas, Polyanthus Narcissi, Primulas, Staphylea colchica, and Acacias. All the plants were fresh and well flowered. Mr. C. Turner showed from the Royal Nurseries, Slough, a number of Cyclamen persicum, all the plants being dwarf and profusely flowered. The foliage of some was particularly well marbled. Another group of Cyclamens was contributed by Mr. J. May, Twickenham. Some of the darker varieties were above the average of merit both in size and substance of flower. Messrs. R. Wallace & Co., Colchester, were represented by a number of Irises, including alata, persica, reticulata, orchoides, and others.

Messrs. J. Veitch and Sons, Ltd., Chelsea, staged a small collection of Amaryllis comprising several varieties of merit, such as Miranda, Leonie, Navala, pardinum, and Dryades. The Chelsea firm also sent a number of superbly flowered plants of Cerasus pseudo-Cerasus grown in differing forms, Prunus sinensis, Staphylea colchica, Spiraea confusa, and Corylopsis spicata. A beautiful collection of Ferns came from Messrs. J. Hill & Son, Lower Edmonton. The plants were of all sizes and many kinds. A very bright stand of several varieties of Azalea mollis was arranged by Messrs. R. & G. Cuthbert, Southgate. Two large collections of Cyclamens came respectively from the St. George's Nursery Co., Hanwell, and the Church Road Nursery Co., Hanwell, each being comprised of well-grown plants.

Messrs. W. Balchin & Sons, Hassocks, exhibited several well-grown plants of the fragrant Boronia megastigma and Tetrathecas. Boronias, Oranges, Acacias, Ericas, yellow Callas, Epacris, and Eriostemons came from Messrs. Cutbush & Son, Highgate, and made a diversified and interesting display. Mr. H. B. May, Upper Edmonton, sent a number of plants of Clematis, including many of the popular varieties, and these

attracted a considerable amount of attention. A large group of miscellaneous flowering and foliage plants was exhibited by Messrs. J. Laing and Sons, Forest Hill, and amongst others were noticed Clivias, Orchids in variety, Amaryllis, Crotons, Ferns, Dracenas, Palms, and Caladiums.

Mr. G. Mount, Canterbury, sent three boxes of Roses in superb condition. The blooms were exceptionally rich in colour for the time of the year, while the foliage was remarkable. P. Purnell, Esq., Streatham, sent Narcissi in pots, as well as several little gems that are usually included under the category of Alpines. Mons. L. P. de Langhe-Vervaeke, Brussels, staged a collection of plants of Butterfly Cyclamens; and Mr. A. Chapman, gardener to Captain Holford, Westonbirt, showed fine new Amaryllis. Messrs. Cripps & Son, Tunbridge Wells, sent freely flowered plants of Deutzia Lemoinei, as well as plants of D. parviflora.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); and Messrs. J. O'Brien, de Barri Crawshay, H. M. Pollett, H. Ballantine, N. C. Cookson, H. Little, H. J. Chapman, F. J. Thorne, A. H. Smee, F. Sander, C. Winn, W. H. Young, E. Ashworth, J. Jaques, E. Hill, T. W. Bond, W. H. Prothero, S. Courtauld, T. B. Haywood, and T. Statter.

Messrs. J. Veitch & Sons, Ltd., staged a very beautiful collection of Dendrobiums, including such as crassinode, Euryalis, splendidissimum, Edithiae, Wiganæ, Cybele nobilius, stratus, and others. The same firm also sent Epidendrums, Cymbidiums, Cattleyas, Cypripediums, Trichopilia suavis, and Phalaenopsis John Seden. Messrs. Charlesworth & Co., Heaton, Bradford, staged a bright group of Orchids, comprising Odontoglossums, Phaius, Oncidiums, and Dendrobiums in many forms. Messrs. H. Low & Co., Enfield, sent Cymbidium Devonianum, C. Eburneo-Lowiana, Dendrobium Brymerianum, Odontoglossum crispum, and O. nebulosum pardinum splendens.

Mr. T. W. Bond, gardener to C. L. N. Ingram, Esq., sent some magnificently flowered plants of Dendrobium splendidissimum. Mr. C. J. Salter, gardener to T. B. Haywood, Esq., Reigate, sent Dendrobium Ainsworthi and a Lælio-Cattleya. Mr. J. Lupton, gardener to J. Rutherford, Esq., Blackburn, sent three Odontoglossums, while several other growers sent one or two plants each. A small gold medal was given to Mr. H. Ballantine, gardener to Baron Schröder, Egham, for a plant of Odontoglossum Baroness Schröder, carrying two flowers. It has been twelve years producing these, and attracted an extraordinary amount of attention.

MEDALS.—Floral Committee.—Silver-gilt Flora to Messrs. J. Hill and Son and W. Paul & Son; silver Flora to Messrs. J. May and G. Mount; bronze Flora to the Church Road Nursery Co. and J. Laing & Sons; and silver Banksian to Messrs. P. Purnell, R. & G. Cuthbert, H. B. May, J. Veitch & Sons, and the St. George's Nursery Co. Orchid Committee.—Small gold to Baron Schröder; silver Banksian to Messrs. J. Veitch and Sons, and bronze Banksian to Messrs. H. Low & Co.

CERTIFICATES AND AWARDS OF MERIT.

Amaryllis Princess Ossa (A. Chapman).—A beautiful variety, of which the colour is very bright red with a white central stripe. The flower is shapely, and of good substance (award of merit).

Amaryllis Navala (J. Veitch & Son).—This is a variety of exceptionally good form. The colour is bright orange red (award of merit).

Azalea grandiflora alba (St. George's Nursery Co.).—This is a grand pure white variety. The flowers are of remarkable size and fine form (award of merit).

Cattleya Miranda (J. Veitch & Sons).—A hybrid resulting from a cross between guttata Prinzi and Trianae. The prevailing colour of the sepals and petals is soft rose, but the broad petals are splashed with crimson. The lip is deep velvety crimson (award of merit).

Dendrobium Ainsworthi, Woodhatch variety (C. J. Salter).—This is a decided advance upon the type (award of merit).

Dendrobium Astræa (N. C. Cookson).—On each of the sepals, petals, and lip of this Dendrobe is a large patch of purplish rose, otherwise the colour is creamy white, the throat being yellow with crimson veins (award of merit).

Lælio-Cattleya warnhamensis (G. Duncan).—A lovely bigeneric hybrid. The sepals are bright orange and the petals purplish maroon, the lip being of a similar colour but much richer (award of merit).

Odontoglossum nebulosum pardinum splendens (H. Low & Co.).—This is, in all respects, a glorified form of the well known type (award of merit).

Odontoglossum Wilckeanum Pittæ (H. T. Pitt).—A superb Odontoglossum, and one of the finest varieties of Wilckeanum that has ever been shown (first-class certificate).

Phaius Norman (Charlesworth & Co.).—This is a hybrid from a cross between Sanderianus and tuberculosus. It is a grand flower. The sepals and petals are very delicate rosy buff with deeper rose venations. The fine lip is purplish crimson at the outer portion, the throat being brown with yellow and white markings (first-class certificate).

Phaius Norman rosea (Charlesworth & Co.).—The flowers of this are rather smaller than the preceding, and the colour is brighter throughout (first-class certificate).

Phaius aurea var. (Charlesworth & Co.).—The handsome lip of this is almost identical in colour with P. Norman. The sepals and petals are pale yellowish buff (award of merit).

EARLY BRUSSELS SPROUTS.—A small quantity of seed of a good variety such as Matchless ought now to be sown in a box or on a slight hotbed, and the plants pricked out when forming rough leaves on a bed of soil in a frame where protection can be afforded. If grown as sturdily as possible good plants will be secured for finally planting the end of May.—E.

THE YOUNG GARDENERS' DOMAIN.

TO OUR BOYS.

HAVING obtained permission to address a little homily to my friends, our young gardeners, I am inclined to wonder whether there are not some, or many, of them "who fain would climb but that they fear to fall" into the editorial arms; or, if under the criticism of their compeers, the few who have, by availing themselves of its space, strengthened their wings for higher flights. Perhaps it is so; perhaps not. I read its columns every week, so smart, so concise, so practical; and suppose that in every bothy in the United Kingdom wherever the *Journal of Horticulture* finds its way (and where does it not?) that this part of its pages is never "skipped." How is it then that only some half dozen bright pens are represented in it?

Is the rising generation of gardeners deteriorating? Is it they have nothing to say, or having it they are tongue-tied; or is it that they are ink-bound? Judging from what I see, and hear, and know of matters generally as they exist in bothydom, other deterrents must account for Young Britain's backwardness in coming forward. In comparison with the good (?) old times of, say, thirty years ago young gardeners of to-day in their position, their dress and address, their education, their attainments and privileges generally, especially in this sympathetic desire to give them scope for careful, thoughtful, intelligent practice with the instrument which has often proved an added power to the spade greater than many appreciate.

"Do you read the articles in 'The Young Gardeners' Domain?'" I recently asked a friend. "Yes," he replied; "and what do you think of them?" "Well," the answer was, "if they are really written by lads then I think their young shoulders have very old heads upon them." I do not endorse that verdict, which brings young gardeners down to the level of Doctor Blimber's establishment, "a great hothouse . . . where all the boys blew before their time, whose mental Green Peas, intellectual Asparagus, and mathematical Gooseberries were common at untimely seasons from mere sprouts of bushes;" but to one less keenly interested such an inference was not, perhaps, altogether unwarranted. In many ways boys are what boys were a few decades ago, and probably will remain so for a few decades to come, but as their opportunities are greater, their responsibilities have increased. Do they feel that it is so? Scarcely as much probably as the exigencies of life demand, for they have no past to compare with the present, or only such as history can give them; and the volatile spirit of youth is apt to fly off to the future, losing itself in contemplation of what it would like to be instead of doing what ought to be done now.

Never before has life attained to so high a tension. It is a veritable struggle to get to the front, and the margin for any slack methods woven from loose imagination is daily diminishing. In this sign of the times lays the signal for action. Do young gardeners see it? Are they fully impressed with its significance? It is, at least the desire, it should be our duty to hammer at every bothy door, and stir up the sleepers to vital activity. I have more than one reason for supposing there are such, and that many a lad's notions of how he will become a head gardener are of "such stuff as dreams are made of."

For one instance, if it is not so, why have so few entered this domain? I am asking a question to which I could, myself give a dozen pertinent answers, but not one of which is the shadow of an excuse. One is "afraid." Afraid of what? "Oh, I could never sit long enough to hatch out such practical pieces as appear weekly;" and still another started too strong and finished too weak; another comforts himself another way, so they are on the wrong side of this domain wall, at the wrong time too, and chiefly owing to some bogey of imagination. Let us hope that—

"Some of your griefs you have cured,
And the sharpest you still have survived;
But what torments of pain you endured
From the evils that never arrived."

One could not reasonably expect many to enter by the teacher's door into "The Young Gardeners' Domain," or gain admittance by shouting "words of learned length, and thund'ring sound;" and yet if you will not use the openings which undoubtedly exist then I fear a lock-out and lock-up by the editorial key will deprive bothydom of a privilege undreamt of in my young days. The duties and the circumstances of life, so far as many young gardeners are concerned, are, in a measure, restrictive. They do not allow of much communion with the greater area of the gardening world, hence many a lad leads a somewhat lonely life, shunning, and properly so, a companionship devoid of kindred taste and aims. From this proceeds the danger of a kind of mental cramp, for "Home-keeping youths have ever homely wits."

It was with a knowledge of this, derived from experience, that I welcomed for their sakes this new departure in garden literature, qualified, I admit, by somewhat selfishly envying them, a prerogative denied to my own youth. Denied, I say, for the scribbling itch peculiar to a certain age, and rather common to it too, was pretty effectually scratched out of me by ultra conservatism displayed then. Scratched, or scotched, only, however, not killed, but the scar remains to emphasise the difference 'twixt then and now. The time was not ripe then, presumably, for young men to wield both pen and spade, but it is now, and are they ready?

Taking the proportion of young gardeners to head gardeners as three to one—that is in gardens of sufficient scope for a bothy, and they are numerous—we have, I think, a rather important section of the gardening

fraternity to deal with, and we look upon it not only with expectation as to the future, but reasonably expect its members to feel that they are now a potent power in the vocation, apart from the brute force of numbers and muscular strength. Will those expectations be realised, and do they, I again ask, recognise their responsibility?

It is not a matter of indifference as to the state of gardening and gardeners when we are gone; no liberal-minded man can so regard it. We elders know that they have a hundred advantages that we never had, but we may not ignore or condemn the innumerable snares and delusions which have sprung up since the days when we were boys together, and consequently escaped. I must apologise for bringing the obligations of "heads" and "hands" together, but I cannot disassociate them; indeed, would suggest to all "Old Boys" the desirability of keeping the young fellows in touch with ourselves, and as a means to the end I would ask them to impress upon the plastic mind of youth the advantages of self-education. We are their keepers, and it is our prerogative—I think our duty—to show them the way in which they should go, and bring them in their early days to feel and to know they are important factors in the great gardening fraternity.

A parting word to our boys. You do not yet quite see the opening for you into the "Young Gardeners' Domain." I have left it till the last that you might see it clearer, or them, rather, for there are a hundred openings. Can you not contribute all sorts of notes and gleanings—not exactly mental Green Peas or mathematical Gooseberries—and have you no question to ask, nothing to learn, or something to say about your surroundings? Will you not tell us the girth of "the big Cedar," the weight of "the big bunch of Grapes," what your opinion is of the—whatever you like, what wild flowers you find in your rambles? Young fellows, I am surprised at your diffidence! I had expected better things of you; do expect them, and as I believe in you I doubt not but that any reasons you may have had, or thought you had, will upon a little reflection disappear, to the betterment of yourselves and the gratification of—
AN OLD BOY.

[With about three exceptions, when "old boys" have addressed the young, as in this case, the whole of the communications which have appeared under this heading have been written by young gardeners, and very well written too the majority have been. Some of them, however, do not appear to be largely endowed with the virtue of perseverance; while a few, we are glad to know, are spending most of their spare evening hours in attending educational classes in technical schools. "Shorthand" seems to have a peculiar fascination to young gardeners, but we have no hesitation in saying that a number of them might benefit themselves more by seeking to acquire accuracy in "longhand," or improvement in the essential art of composition.]

HARDY FRUIT GARDEN.

Pruning Filberts and Cob Nuts.—Owing to the necessity of having plenty of catkins or staminate flowers to produce pollen for the fertilisation of pistillate flowers, annual pruning of Filberts and Cob Nuts is deferred until the female buds are fully open. These are known by their tufts of crimson styles protruding from the buds. They are usually situated on the upper parts of young shoots, as well as on spurs, and short twiggy growths. The male flowers hang in long drooping catkins. When fully mature the pollen falls when the catkin is disturbed either by shaking or moved by the slightest wind. After fertilisation has been effected, shoots furnished with catkins may be shortened back. Weakly branches or any that crowd the trees might with advantage be removed before the flowering period, also any superfluous growths tending to crowd and obstruct the necessary light and free circulation of air.

Young Trees.—Suckers or very young trees must be pruned with a view to the production of wood for the formation of the trees. In the case of a sucker with a single shoot shorten it to 18 inches. From the buds which start select six of the strongest, training them at equal distances apart, a hoop secured between them in the centre affording the best means of doing this. The following year prune back each shoot to a length of 4 inches, and allow two growths from each. This will afford a fair number of branches and give a well furnished tree. Pinch the side growths to five leaves. Very strong growths pushing from any part of the trees will have the effect of robbers, and should be closely removed. The free formation of side shoots is best encouraged by shortening the main growths or leaders in winter according to their strength. The weakest may be pruned more closely than those of medium or more strength. Cut the weakest back two-thirds, the strongest one-third.

Removing Suckers.—Young suckers at the base of trees or bushes or at a distance away, if not wanted for planting, should be dug up and destroyed.

Protecting Apricots.—Apricots being the first of stone fruits to open the blossom, means must be taken to duly protect it from inclement weather. Cold dry weather does not materially affect it, but it is liable to receive injury when the weather is wet and boisterous followed by

frost. Even when there is no frost, wet and wind alone are capable of damaging the essential organs of the flowers, hence the necessity of keeping them dry if possible. Blinds of tiffany, frigi domo, and other material drawn down over the trees and supported so as not to touch the flowers will keep the latter dry, but as a mere protective covering to ward off frosts double or treble lengths of fish nets act well. These can be affixed in front of the trees and remain permanently until the need for protective coverings ceases. In the absence of a coping from which the material can be suspended poles may be reared against the walls and the material stretched across them. Although fish netting may be left on permanently other material must be removed or drawn on one side, so that there is no obstruction of light and air on favourable occasions.

Strawberries.—*Planting.*—New beds or quarters of Strawberries may be formed this month, although the plants ought not to be allowed to bear fruit, but instead encouraged to make vigorous growth and plump up bold crowns for the succeeding season. The best plants for present planting are those which were placed in nursery beds in the autumn for the purpose of strengthening. They should lift with good balls of roots and soil. Plant firmly in well dug and manured ground. Young plants having no soil attached to roots, such as those recently procured from the nursery, must be planted with a considerable amount of care. The roots should be kept moist, and when planting spread them out equally on mounds of soil, covering them carefully in the same direction as the roots lie, so as not to turn up the points. This will assist them to more readily take hold of the soil, and become well and quickly established.

Autumn-planted Strawberries.—Should any plants have become loosened it is desirable to make the soil about them firm again, afterwards running the hoe between the plants, cutting down weeds and moving the whole surface to admit air and promote growth. This is best carried out in dry weather.

Established Beds.—The remains of the winter mulching may be raked off, also weeds and withered foliage removed. Dust the soil round the crowns with soot, which will have the effect of destroying slugs lurking there, at the same time benefiting the roots. When the surface has dried and sweetened for a short time, afford another mulching of manure, this time employing rather fresh material. The soluble part of the dressing will gradually be washed into the soil, leaving the strawy portions as a clean rest for the ripening fruit subsequently.

FRUIT FORCING.

Vines.—*Earliest Forced Vines in Pots.*—The canes started last November have the Grapes in the last stages of swelling, and must be adequately supplied with water, liquid manure, and rich surface dressings, while if the roots extend beyond the pots feed them there as well as in the pots. The very early varieties, such as White Frontignan, Foster's Seedling, Black Hamburgh, and Madresfield Court, are well advanced towards ripening, and will only need clean tepid water after the colour is well pronounced. A circulation of warm moderately dry air conduces to the flavour of the fruit, but the Vines must not lack the needful supplies of water to keep the foliage fresh, nor the atmosphere be allowed to become so parched as to invite red spider, and a moderate amount of atmospheric moisture without stagnation is essential to their remaining plump and fresh until cut.

Early House.—Vines started early in December and previously forced will soon have the Grapes stoned, and should have copious supplies of tepid liquid manure. A light mulching of lumpy partially decayed manure may be placed on the border, as the Grapes swell considerably in their later stages, even after colouring commences, and allow a liberal extension of the laterals, as every leaf encourages root action, and that leaf duly exposed to light and air aids the Grapes in swelling and finishing. The Vines started later in the year, and of which the Grapes have been thinned, will need liquid manure applied to inside borders; but surface dressings are more potent in accelerating and keeping surface roots, and a good handful of the advertised fertilisers per square yard makes a wonderful difference in the colour of the foliage, and this means ultimate good colour and finish in the Grapes.

Vines Started at the New Year.—The Vines have made satisfactory progress, starting freely without showing a tendency to twist and twirl in the bunches, which are now in flower. Afford a rather dry atmosphere with a gentle circulation of air, and a temperature of 65° to 70° at night, and 70° to 75° by day artificially, with an advance to 85° from sun heat, maintaining moderate moisture by damping the house two or three times a day in bright weather. Muscats should have a temperature at least 5° higher, and the flowers must be carefully fertilised. Avoid the close stopping system until nearly every part of the trellis is well covered with foliage, then allow no more than there is room for. Do not permit the border to lack moisture, and when the Grapes are set supply liquid manure or top-dressings of fertilisers, washing into the soil moderately.

Succession Houses.—Disbud and secure the growths as they advance, stopping them two joints beyond the bunches where the space is limited; but where there is room allow a greater extension of the shoots before stopping. Remove the laterals from the joints below the fruit except from the two basal leaves, stopping those at the first leaf and to one afterwards as produced. The laterals above the fruit may be allowed to make such growth as can have exposure to light without crowding and then be stopped, keeping them pinched afterwards, as well as those not having room for extension. Remove all superfluous and ill-formed bunches of the free-setting varieties as soon as those that are the most promising for the crop can be selected. Maintain the borders in a proper state of moisture, and secure a genial atmosphere by damping the house well at

closing time, as well as in the morning and evening. A temperature of 60° to 65° at night is suitable after the Vines come into leaf, allowing 65° to 70° on dull days and 75° to 85° with sun and ventilation, taking care to ventilate early, to avoid draughts and to close early.

Vine Eyes.—These having been inserted as advised are now rooted, and should be potted singly, or if placed in small pots they must be shifted into 6-inch as soon as they reach the sides of the smaller, standing them on shelves over the hot-water pipes. Syringe well amongst them, and pinch the laterals at the first leaf, unless the Vines are intended to be planted out this season and not fruited the next, when the laterals may be left entire, but in that case planting must be done before the roots become matted.

Cut-back Vines.—For fruiting in pots next season these Vines will now be fit for shaking out and repotting, or if that has already been done and the roots have reached the sides of the pots, they will need shifting into the fruiting—12-inch pots. If they have been given bottom heat they should be returned to it for a time, 75° to 80° being sufficient, otherwise bottom heat is not necessary, yet the pots are better stood on slates over hot-water pipes than on a cool base. Keep the house close and moderately moist until they become established. Train the canes near the glass, pinching the laterals to one leaf, and thus secure solid growth and plump buds. Use clean pots and efficient drainage. Turfy loam with a fifth of old mortar rubbish answers well for potting, but a pint of bone superphosphate, a quart of soot and two quarts of wood ashes to a barrowload of compost, greatly improves it for the Vines.

THE BEE-KEEPER.

THE WEATHER.

THE exceptionally fine weather experienced during the first two months of the year deserves to be chronicled. In the Midland counties bright sunny days have been the rule, and not, as is often the case, the exception at this season. The rainfall, too, is remarkable, as during January 0.49 inch fell on five days, and February 0.64 inch on eleven days, the total for the two months being 1.13 inch, which amount fell on sixteen days. In the West and South of England, also in Scotland, there were heavy falls of snow in February. This we happily escaped, although the melted snow would add considerably to the moisture in the land, which will eventually be an advantage to bee-keepers in those districts.

But what will be the effect of a mild winter and a light rainfall on bee-keepers? Much will depend on the amount of moisture we have during the early spring months. At the present time the herbage in the fields and by the roadsides is as forward and looks as green as it often does by the first fortnight in May. The two important crops—field Beans and white Clover—are looking well, and, like all other vegetation, are well advanced. If severe frosts come these will certainly suffer, and the flowering season will be retarded. If a heavy downfall of rain come it would do a great amount of good, and then, should the fine weather continue, an early harvest of honey may be expected.

It is often the unforeseen that occurs, and for want of attention at the right time many stocks will doubtless be lost, or so impoverished, owing to a shortness of supplies, that the bees will be unable to take advantage of the early flowers should the favourable weather continue. If the bees are short of stores they will make little headway until the natural supplies are coming in freely, and there is thus a great loss of time, which all bee-keepers should endeavour to guard against.

EXAMINING STOCKS.

The less bees are handled or interfered with at any time the better. During the summer and early autumn it is not necessary to observe the same caution as at this season. All that is required is to find out if sufficient stores remain in the hive. How is this to be done without disturbing the bees? In our apiary we can judge accurately by simply lifting the back of the hive with one hand, and with a little practice anyone may become an adept at judging the weight of the various hives. This is much easier when they are about the same size, and the wood of similar weight and thickness.

There need be no difficulty in this respect, as we have hives constantly in use, which have from ten in the smaller or ordinary hive to upwards of twenty frames in the larger size. If the frames are all of the same size throughout the various colonies it is better, even when one is judging the weight of stores, than when they vary several inches in width or length. Where numerous colonies have to be examined this is a great saving of time. If any doubt exist remove the outside covering from the quilt, and lift the latter from the sides until the frames outside the cluster are bare. By looking down between them the sealed stores (if any) will be visible. If a few square inches are to be seen on a couple of the frames on one side of the cluster all will be well for a few weeks longer. If the stores are

found to be nearly or quite consumed, feeding should not be delayed any longer. The operation must only occupy a few moments.

A mild day for preference should be chosen for this purpose, and it is a good plan to examine all the stocks in the apiary at least once a fortnight from this time onwards until outdoor supplies are coming in freely. We would advise all bee-keepers who have not already tried the plan of lifting the back of the hive to try the weight and prove, if any or what quantity of stores remain in the hive, to do so in the future, and they will doubtless be surprised to see how easily it is done. It has the advantage, too, of being independent of the weather, as well as a great saving of time and labour.

FEEDING BEES.

Although feeding bees is a necessity at this season if their natural stores are consumed, it is not good practice to unduly excite the bees at this early date. The best artificial food for the next few weeks is candy, made as advised in previous notes. This should be placed directly over the brood nest. It may be placed on the top of the frames under the quilt; but as mischief is sometimes done by not placing the quilt and extra covering snugly over the whole, we prefer to cut a hole through the quilt as well as the next cover, turn the flaps back, and place the cake of candy directly over the aperture. The quilt will then remain firmly secured on the frames, and the bees will be warmer in consequence.

The whole should be covered with extra coverings; this will prevent an escape of heat, so important at all seasons, but doubly so during the winter and spring months. The advantage of leaving the flaps on the quilt and covering will be seen on removing the box in which the candy was placed, by the readiness in which they are placed over the aperture, and so confine the bees to their hive.—AN ENGLISH BEE-KEEPER.

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Tulips not Flowering (E. D.).—The bulbs were, in a sense, "blind," the result of imperfect development of flower buds in embryo, generally attributed to some defect in treatment or the intervention of some parasitic organism. The roots and leaves are healthy, and there is no evidence of mismanagement.

Autumn Grapes (Young Head).—Vines intended to afford Grapes for use in August onward must now be started, and Muscats, with other varieties, to produce Grapes for keeping, should be encouraged to move, as the fruit hangs much better when ripened in August, or early in September, than when the season is more advanced at the ripening period. Vines which have only been recently pruned should be given a little rest before starting them, yet all thin-skinned Grapes, and those taking a long time to grow and ripen, should be started not later than early April, for they require all the sun that can be secured to them, and should be assisted with fire heat all along, as upon thorough ripening depends their keeping sound. Inside borders may be brought into a thorough state of moisture by the application of water at a temperature of 80°, or not less than the mean of the house, and if followed by an application of liquid manure, but not too strong, it will make a considerable difference later on, inciting root action and nourishing the Vines.

Manure (C. Lincoln).—Your sample arrived too late for examination for the purpose of a reply such as may be useful to you in our present issue.

Plants for Germany (Commercial).—You have been correctly informed. In shipping plants for Germany the consignor must make an affidavit before a Commissioner deposing as to the country and locality in which the plants are grown, and make affirmation that there is no phylloxera in the district, then send it to the German Consulate at 46, Finsbury Square, for verification before shipping the goods.

Eucharis Bulb (St. J. A.).—Yes, the "Eucharis bulb has mite," for the most part in the egg state, but the bulb was very dry when received, so the mites may have collapsed if any young were on it. They will certainly endanger the healthy plants, hence those affected ought to be isolated and treated with either Clibran's Eucharis mite killer, following the instructions, or Little's soluble phenyle in the proportion of a wineglassful (2 fluid ounces) to 3 gallons of soft water. Treatment with hot water also answers well, the temperature not being less than 130°, or exceeding 135°; but it has not the after beneficial action of the other articles named.

Early Vegetation in Ireland (J. S. C.).—Your letter arrived one post too late for insertion last week, and this week we have exceptional pressure on our space, so much so that several excellent articles cannot be inserted. We observe "that Clematis montana has been flowering splendidly at Balbriggan, co. Dublin, for a month; that Gooseberry bushes are quite green; also, that Peas sown on January 18th are advancing well up the stakes in a strong and healthy condition." We are pleased to publish notes of interest from Ireland from time to time, but they should reach us not later than Monday for insertion in the current issue. We are obliged by your letter.

Salt (Asparagus).—Our practice in applying salt to Asparagus beds has always been to wait for the appearance of small weeds, and then apply sufficient salt to kill them. About 3 ozs. per square yard will do this, and a few saltings during the season keep the beds clean. Salting during the winter is apt to make the soil too wet. We have found the addition of 2 or 3 ozs. of superphosphate of lime a valuable addition, applied early in March. A very small amount of salt mixed in manure would do no harm in your dry soil, but excess must be guarded against. About 7 lbs. blended in a cartload would be safe. Trenching the land and spreading a good layer of decayed manure, from cowsheds, a foot below the surface would be helpful to the Peas, as would a good layer of manure along the sides of the rows on the approach of dry weather.

Situations (G. G.).—We are pleased to hear that the insertion of your advertisement in the *Journal of Horticulture* was the means of obtaining for you a situation. We hope it will prove a good one, and that both your employer and yourself will be satisfied with the connection. This is the second notification we have received this week of gardeners being successful through the same means. Other excellent men are not equally fortunate, and must find it weary waiting for appointment to vacancies that they could fill so well. These are not the days for gardeners to lightly relinquish situations, but of course the retention of them is at times impossible. Three years ago we had the pleasure of assisting a gardener to obtain a very good charge. He acknowledged this for the first time last week by informing us on a postcard that "he had been very comfortable, but had given notice, as he wanted a change, and no doubt we should soon find him what he wanted." That was all, and enough for a card, but we are bound to inform him that his turn does not come next.

Old Apple Trees (O. F.).—We presume your trees are in the open and not growing against walls. By all means remove those branches that appear so enfeebled as to be unable to produce strong blossom buds, also all interior growths, cutting them smoothly away close to the main stems from which they spring. Only the more healthful and promising branches should remain, and these at such a distance that the leaves of one cannot touch the leaves of another in the summer. The removal of many branches now will probably be followed by numbers of young shoots pushing from the main branches in spring. Do not permit these to grow to any length and then cut them back, but when they are an inch long or so have them rubbed out of their sockets. Perhaps the advice given on page 219 on thinning, cleansing, and improving old fruit trees may be of service. We are pleased you find the *Journal of Horticulture* helpful, and shall gladly give such assistance as we can in any difficulties that you can make clear to us. Healthy thinly disposed young growths if not shortened will become studded with blossom buds.

Double Flowers (Journeyman).—We are pleased to hear you have been attending lectures on gardening. That is what all young men should do who have the opportunity and desire to become competent gardeners. It is possible that you may hear something with which you may not agree, and in this case so much the better, if it set you a thinking and lead to research or inquiry. Lecturers differ, of course, and the best of them are the most ready to admit that they have something to learn. In the present case, however, the lecturer was right in stating that a completely double flower could not produce seed. The instances you cite to the contrary are delusive. Neither a so-called double Carnation, Primula, or Wallflower that produces seed is completely double. It may appear so and be far removed from a single by a multiplication of petals, but lurking among them might have been discovered the essential organs—stamens and stigma; it is not till these are changed into petals that the flower is perfectly double, and when this occurs there are no organs for producing seed. A so-called double Chrysanthemum is an aggregation of a great number of single flowers closely packed together on a common head or capitulum.

Blood Manure (F. S.).—It is necessary to have an earthenware vessel, a wooden one absorbing the acid, and otherwise being unsuitable; also to use the saturated solution of the hydrochloric acid gas, which contains about 42·4 per cent. of real hydrochloric acid, the muriatic acid of commerce containing about 32·6 per cent. Above all allow the blood to become rancid or smell strongly before treating with the acid and iron. For some reason the recipe has not always answered its purpose, and chiefly from those points mentioned not being attended to.

Japanese Irises (J. D. Waugh).—You ask "in what way these Irises differ from others?" We might ask, From what others? for the diversity is great indeed in this beautiful genus of flowers. There are the gorgeous Flag or German Irises, bearded and non-bearded, also the hulbous English and Spanish Irises, with smaller and very beautiful flowers, as

FIG. 50.—IRIS LAEVIGATA.

familiar well marked types. Japanese are Flag Irises, like the German section and non-hulbous; but the flowers are quite different in being much flatter, and many of great size and richness in colouration. Their character is represented in the illustration obligingly furnished by Messrs. Barr & Sons, but the blooms are thrice the size of those in the figure. These Irises only thrive satisfactorily in moist soil, and do not object to some peat in it. They seem to be of a semi-aquatic nature, and are grown near a stream at Long Ditton. Mr. Joseph Chamberlain has a bed devoted to them on his lawn at Highbury, with perforated pipes running through it connected with the water main. In the summer the water is turned on, and the bed maintained as a swamp, but kept drier in winter. It is not a sour bog, as provision is made for conducting the water away as and when required. The plants luxuriate and produce their gorgeous flowers abundantly.

Nitrate of Soda Solution (H. T. H.).—Though a valuable product this is by no means a complete manure, and if used alone over any long period would probably do more harm than good. You do not say for what kinds of plants you intend applying the solution. It is likely to promote leaf growth at the expense of stem substance and floriferousness. You had better proceed experimentally with a quarter ounce to a gallon of water, and even this may not be beneficial to all kinds of plants. You may also bear in mind that nitrate of soda lowers the temperature of water, and that in itself might be prejudicial to some of your plants.

Names of Plants.—We only undertake to name *species* of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once,

and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Weekly Subscriber*).—All the Crotons of which you send leaves are "varieties" of evidently well grown plants, and can only be named by actual comparison with others. If you deal with a nurseryman who has a large collection he will name them for you. As you will see by the notification above, we only name "species." If you can send us a flowering spray of the other plant, of which we presume you require the name, we will endeavour to supply it.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state.* (D. G.).—A very fine specimen of Beauty of Hants. (O. F. E.).—1 D'Arcy Spice; 2, Braddick's Nonpareil; 3, Scarlet Nonpareil. The Pear is Josephine de Malines.

A MODEL.

(Continued from page 116.)

WE now come to the consideration of the flock of sheep. How many ewes would the farm of 100 acres carry, and what breed would be most suitable and profitable?

As we have taken for granted that the animals would be required for home consumption, either as fat lambs or as hoggets, one of the Down breeds should certainly be chosen as the best from which to select the breeding ewes. Hampshire Downs are good sheep for the purpose, as they breed early and come early to maturity; but we should not keep a pure flock, because there would not be room for the gimmers during summer without reducing the number of ewes, so it would be found better to buy in ewes after midsummer according to the annual requirements.

We should recommend the use of a Lincoln ram, the cross between Lincoln and Hampshire Down being generally successful in producing lambs which, if they miss going off fat as lamb, will make good, well developed, and heavy sheep for autumn and winter killing, and should always come to profit before they are twelve months old.

The number of ewes to breed from would depend much on the number of fat lambs required. For grazing through the summer the seven acres of Clover would not carry more than twenty ewes and their lambs to do them well; but early fat lambs might be had independently of this Clover by growing an acre of Cabbage instead of an acre of Mangold. If the Cabbage were drilled in April the crop should be ready for consumption in late autumn or early spring. Thirty-five ewes put to the ram in August ought to lamb down in January and February, and if only a dozen of these be fed off with their lambs before May the seven acres of Clover should be enough to see the remainder through the summer. Of course, the Cabbage would be very important in getting the early lambs forward for killing. There would be plenty of well sheltered grass land on which to put the ewes after lambing, and if they had a liberal allowance of cake and Mangold for the first month, then a few Cabbage for a change when the lambs began to eat, there would be little need to stock the seeds until at least the earliest lambs had been sent to the butcher. If the winter were mild, and the earliest Tares very forward—i.e., too forward—the lambs would do well on them for a few days, and whilst the change of food would do them good they would do the Tares no harm.

We should not take the lambs Mangold or Cabbage whilst on the Tares, preferring to put them on the Tares for a day or two at short intervals for a change than to keep them on for any length of time.

The artificial food given to ewes with lambs, and particularly to those with early lambs, should be something suitable for the lambs themselves to eat and digest. To mature rapidly, the animal must eat as well as drink; and, as a rule, what suits the lamb's digestion will also stimulate the milking powers of his dam. Many forms of mixed cake are made suitable for this purpose. Lamb foods, whilst being most valuable in their own sphere, are not the best used for fattening, their greatest use coming in after weaning, when the young animal first really misses its mother's milk, and progress is not so much looked for as the retention of what has hitherto been acquired.

There are several excellent makes of the cake we recommend. They are generally made of a round shape; they should be fairly soft and easily broken, and on analysis should contain as much oil as an average linseed cake. With 24 acres mown every year, there should be no difficulty in keeping the lambs from weaning until they could be got on Turnips; there would not be much more than one lamb for each acre of aftermath, and with a little lamb food and a few Mangolds, if any were left over, they should hold their own at the very least. Cattle would also be run on the fog, and the lambs might either be run along with them over the whole 24 acres, or one field retained on purpose for them; but in the latter case the cattle and lambs would

both benefit from an exchange of pasture at least once during the two months or more during which the lambs would be on the grass.

In this connection lambs are generally best kept without a supply of water, unless the water be a running stream and very pure, but they are safer without any; for at this stage their stomachs are easily upset, and if they are a little feverish and have an unlimited supply of water they are very likely to drink more than their systems can absorb, and bring on pneumonia, followed by rapid decease.

Every effort should be made to get these cross-bred lambs fattened off before February, as we have found them very liable to lameness as the days lengthen and March approaches.

The ewes from October until they lamb down would have plenty of room on the grass land, and with a little hay and malt culm would not require a great many Turnips; if there were very little grass on the meadows of course it would have to be supplemented with Turnips to a moderate extent, but roots should not form more than half the ration of the ewe at any time.

During autumn breeding ewes are no worse for being kept a little low in condition, but during the last eight weeks of pregnancy they must be well fed. We are in the habit, when we notice an ewe looking a little below par about Christmas time, to put her on cut Turnips and cake with the feeding sheep, and it is wonderful to see how good the result invariably is.

WORK ON THE HOME FARM.

Though the frosts have not been severe, they have made the land firmer for carting upon, and we have been glad of the opportunity to get some manure from the yards, also to get sundry heaps of compost placed where they will have the chance to make a grateful return for the care taken of them.

The manure has gone straight on to the land now being prepared for Potatoes; it is practically fresh made, but a portion of the same field will be dressed with a heap of old rotten manure; both portions will have sulphate of ammonia given as a top-dressing, which will give the best result. If all we are now hearing be true with regard to the effect of manure on artificial nitrogen, the old manure should do best, as we are told that fresh manure will send off the nitrogen from nitrate of soda in about fourteen days. It would appear, then, that we had better apply our sulphate elsewhere; but "seeing is believing," and we shall try the experiment and note the result.

We are ridging our land about 26 inches wide; this is quite narrow enough to cart upon without spoiling the ridges. We make our ridges for later varieties 28 or even 30 inches, but this field is to be planted with Elephants, and anywhere between 24 and 26 inches will do for second earlies. The seed is just budding, and we shall get it put in at once, taking care to get it well covered up from frost and birds.

Lambing has hardly commenced here, but we hear of good progress being made here and there. Complaints are made of ewes lambing down slowly; this may be owing to the dry season more than to any large proportion of the animals being barren.

It is very satisfactory to hear that Colonel De-la-Bere's proposed national poultry test has been so well taken up and will be well carried out. We cannot see, however, why there should be any hard and fast rule about feeding; it would have been more instructive to have had a record of the results attained by different systems of feeding as well as a general answer to the question whether egg-production pays.

27th.—Dull, with frequent slight rain in morning; storm rain with hail at 2 P.M., then generally bright, but rain again at 4.30 P.M.

28th.—Sunny morning; fair afternoon and evening.

1st.—Variable, threatening at times, and rain and hail from 1 to 2.30 P.M., but much bright sun.

2nd.—Alternate cloud and sunshine; spots of rain at 2 P.M. and 3 P.M.; bright night.

3rd.—Sunny till 3 P.M.; rain and wet snow at 4.45 P.M., and rain or snow from 7.30 P.M. to midnight; the ground white.

4th.—Overcast till 9.30 A.M., then sunny; conical hail at noon and 1.55 P.M.; sunny again from 2.30 P.M.

5th.—Fine, and frequently sunny.

A week with average temperature and rainfall and much bright sunshine.—G. J. SYMONS.

BARR'S CHOICE FLOWER SEEDS.

A FEW SPECIALITIES.

ANTIRRHINUM, BARR'S QUEEN OF THE NORTH, snowy white, fine habit. Per packet, 6d. and 1/-.
 AQUILEGIA, BARR'S LONG-SPURRED, extra selected. Per packet, 2/6.
 ASTER, "PEONY PERFECTION," carefully selected; a beautiful mixture. Per packet, 1/- and 2/6.
 BALSAM, BARR'S CRITERION MIXED. Per pkt., 1/6 & 2/6.
 CELOSIA PLUMOSA, MIXED, a beautiful strain of this graceful annual. Per packet, 6d. and 1/-.
 CINERARIA, BARR'S PRIZE. Per packet, 2/6 and 3/6.
 COCKSCOMB, BARR'S EXHIBITION. Per pkt., 1/- & 1/6.
 COREOPSIS GRANDIFLORA, BARR'S SELECTED STRAIN. Per packet, 1/-.
 DELPHINIUM, BARR'S MAGNIFICENT "LONG DITTON" STRAIN. Per packet, 1/6 and 2/6.
 TREE LUPINS, BARR'S FINE STRAIN. Per packet, 1/-.
 PETUNIA, BARR'S SUPERB GIANT. Per pkt., 2/6 & 3/6.
 POLYANTHUS, BARR'S HIGHLY COLOURED. Per pkt., 2/6.
 PRIMROSE, BARR'S HIGHLY COLOURED. Per packet, 2/6.
 PRIMULA, BARR'S "COVENT GARDEN" CHOICEST STRAIN. Per packet, 1/6 and 2/6.
 STOCKS, BARR'S TEN-WEEK CHOICE DWARF STRAIN, in mixture. Per packet, 1/- and 2/6.
 SWEET PEAS, BARR'S CHOICE MIXTURE of Newest and Finest Sorts. Per packet, 1/- and 1/6.
 BARR'S SEED GUIDE (free), contains a Descriptive List of the best Vegetables and most beautiful Flowers.

THE COMMON IDEAL IN FRUITS AND VEGETABLES.

ONE of the most striking features in the commercial fruit culture and trade of these times is the extent to which, in certain instances, appearances have relegated quality into a consideration of secondary importance. If the chief end of fruit culture be to produce beauty of form and colour instead of quality, of course no objection can be taken to the ideal aspired after. From an æsthetic point of view it is all right. The question, however, may be asked, Is this the most correct and true ideal? Many will be able to corroborate the fact that quality is the first point to the best trained palates and most refined taste.

It is only necessary to send a basket of fine Black Hamburg Grapes and one of Gros Colman to market to find that the general crowd of consumers is satisfied to give a higher place and price for the "Colman." It may be early in October, when it is barely coloured, green round the foot-stalks, and requiring another month to ripen. The flavour may be bordering on nastiness, have a smack of foxiness and earthiness for want of a longer season and more fire heat. The Black Hamburg may be ripe, vinous, toothsome, and jet black; but because it lacks the mere bulk of its rival it is slighted. Is not this something approaching to a vulgar taste?

The public demand in this respect rules the lines on which the market grower works if he is to make his industry pay. Hence the really fine relishable article is elbowed from the market as soon as its larger, unripe, and altogether coarser competitor can be brought into it. Some say of this state of matters, "Where ignorance is bliss, 'tis folly to be wise." This preference is not altogether kept outside the gardens of those who know better, and prefer the less showy to the merely larger and coarser Grapes.

Perhaps the preponderating encouragement offered by horticultural exhibition schedules to mere bulk may be credited with a considerable share in these results, not only in reference to Grapes but to vegetables as well, but specially to

No. 2581.—VOL. XCVIII., OLD SERIES.

Grapes. The easily grown, showy, and scarcely second-rate Grapes have met with an extent of encouragement which they do not deserve, as compared with the more difficult but most worthy of culture for the greater part of the year. For the sake of gaining the admiration of—in this matter—the uneducated crowd that attend such exhibitions, but do not appreciate the products by any other standard than mere size and appearance, this may be so far right.

Judges are often sorely puzzled in coming to a conclusion, and in making awards to satisfy themselves when dealing with collections of mixed and unspecified Grapes; and very often when they think they have done right in giving most points to quality instead of size or appearance, they cause dissatisfaction to the exhibitor.

It would do more justice to the respective varieties if the larger collections of six and eight Grapes could each be pitted against the same varieties. Instead of this, one mixed lot is pitted against another mixed lot of diverse kinds, and the correct decision becomes more difficult. Surely such large classes could be arranged the same as for one, two, and three bunches which in the same schedule are confined to one variety. I am quite certain fine Grapes as regards quality suffer injustice from being thus mixed with others. No lover of really fine Grapes would choose size and appearance as against quality and the best finish of the high-class Grapes. Surely more of fine and beautifully finished Black Hamburgs, if treated on their merits, should find their way to our September shows. You, Mr. Editor, must have had an example of large houses full of Black as Sloes Hamburgs in the autumn of the year, and there is no reason why plenty of good ones should not be in evidence till December at any rate.

Take the case of Tomatoes as an illustration of how, in some instances, quality has to take a back seat in order to suit the public taste. Here the case is somewhat reversed. Small ones are preferred up to a certain size, and they must be round and not a wrinkle in their skin. No matter if they have a thick rind instead of a thin skin, and be next to a bagful of seeds and green core, provided they be the orthodox size. The larger ones may be almost seedless and entirely coreless, the flesh mellow and of the finest flavour, yet the market will have none of them. I bought Tomatoes last season for the first time, but did not continue the experiment.

When Excelsior came out many years since I thought more of it than any of the many I had previously tested, having the quality I have indicated in a fine Tomato. For a number of years I selected from it, choosing the fruits with fewest seeds and no cores or open lobes. The result was a selection I have never seen equalled by any of the numberless market sorts I annually tested against it; but the market would not patronise it simply because it was too large, and yet not very large, and some of the fruits came not quite round and smooth. Here appearances carried the day, and I think you in this instance can endorse what I have said of its qualities. I like to see, and have produced, size in many things; but I think quality should be the predominating feature.

I will give one more illustration from Celery. Large, tall, coarse growing Celeries are much run after in preference to dwarfier sorts that are white, firmer in their growth, nutty in flavour, and because of their stature much less laborious to grow. No matter how tall and bulky a Celery may be, its useful part is never in proportion. When sent for use the salad mixer and the cook strip them of their coarse outsides till they are of comparatively small dimensions. If sent up as a cooked dish they have to be stripped to obtain what is white, solid, and useable, till they are little if any larger than the dwarf, compact, and more solid and better flavoured sorts. I remember a sample of large heads being sent to a ducal kitchen, but they were condemned by the *chef* as coarse and soft. More subjects could easily be named to illustrate how in relation to them a false ideal is aspired after, but I will refer to only one more instance.

Strawberries for preserving give an excellent illustration of the sacrifice of quality for size. It is not at all an uncommon practice to grow some large variety for the purpose, and one that produces a preserve that cannot be admired, either from an æsthetic or flavour point

of view. It cannot possibly in these respects be first-rate. Looking at the preserve it might be called almost any name, for no signs of a berry can be recognised in it. They all boil to a pulp. All first-class housekeepers and confectioners with whom I have had to do condemned that state of matters. The Strawberry I have found them to like best, and I quite approve of their decision, is the old Grove End Scarlet. It has almost every good point for this purpose. It is below medium size, of a brilliant red colour, and when picked at the proper stage of ripeness is of good flavour, and when boiled the berries remain whole, and the colour is a bright red. It should be gathered immediately it is fully coloured, and before it gets in any way soft. It has still more good points—it bears abundantly, and the same plants will do so four or five years; and as it gives many pickings in succession it is bad to beat, even for bulk of produce.—D. THOMSON.

[We are in general agreement with our correspondent. It is true we have seen magnificent Black Hamburgs from the end of April till the end of October and later, but the finest late house we can call to mind was at Drumlanrig in 1896. We also know our friend's Tomato very well—its substance, colour, and quality. We know of no Strawberry for preserving equal in all points to the Grove End Scarlet, but we have to be content with small fruits of Vicomtesse Héricart de Thury now. These, preserved with $\frac{1}{2}$ lb. of sugar to 1 lb. of fruit, have retained their shape and lost little of their flavour when gathered but lack the clear brightness of the Grove End Scarlet. We are disposed to think that the cult of size worship, especially in vegetables, is on the decline; but this remark does not apply to Onions. We wonder what our esteemed correspondent thinks of those which approach the size of footballs. He does not object to large Tomatoes, when they are also good.]

NOTES ON INDIAN AZALEAS.

INDIAN Azaleas are among the freest and showiest of our spring-blooming plants. They merit a place in every collection. They do not require a higher temperature at any period of their growth beyond what can be given them in an ordinary greenhouse or vinery. The range of white and beautifully coloured flowers which a large collection of these plants is capable of supplying entitles them, however, to put forth a powerful claim for a separate and exclusive house, seeing that the flowering period may be extended all through the spring months, and as far as June.

Azaleas are raised by grafting on free-growing stocks, such as *Azalea alba*, and by cuttings. The latter method requires that a certain state of the cutting should be secured when inserting, and skilful attention in carrying out the details necessary to obtain success in rooting them. I am acquainted with a good cultivator of Azaleas, who propagates many plants by the cutting system, and thus constantly renews his stock. The average grower, however, wants plants to begin with that are already prepared to flower when a decision is made to grow them. Fortunately he can be supplied quickly and cheaply, good plants, with splendid symmetrical heads full of bloom buds, being obtainable at 2s. 6d. each. Many can be had at less rates, though necessarily smaller plants, while larger may be had at proportionate prices.

Although the material Belgian plants have been grown in is quite different from that we employ for Azaleas, they nevertheless usually do well under our treatment. On the Continent they are grown entirely in leaf soil, and according to their appearance when they arrive here it appears to suit them admirably, but the leaf soil is natural, or unfermented, being quite suitable for the growth and perfection of the Azalea. As we mostly understand leaf soil in this country the leaves are decomposed quickly by fermentation in large heaps. This would not prove good for Azalea cultivation in a general way, but on the Continent it is prepared in a more natural manner.

In this country, however, leaf soil cultivation is out of the question, peat of a turfy fibrous character taking its place. In the North the best peat is considered to be Kent peat, but from what part of Kent it is obtained I cannot say, but wherever it comes from it should be full of vegetable fibres, which hold it compactly together, but can be pulled to pieces by the hand. That which falls into dust, and contains a large proportion of the rhizomes of Ferns, especially the common Bracken (*Pteris aquilina*) is unsuitable for hardwooded plants in pots; it is usually spongy, and soon becomes sour.

Plants obtained direct from nurserymen are ready potted, and need not be disturbed until they have flowered once or twice. Most growers desire to increase the size of their plants. A shift into good soil will encourage free growth, but it must not be overdone, a pot two sizes larger being ample. In potting Azaleas it is important that the pots be clean and firm. Those that are cracked, even slightly, ought not to be used, for this particular reason, that a stronger pot is necessary when potting the Azalea than for most other plants, because the compost must be pressed down hard, and it is only good pots that can withstand the strain put upon them. It is very annoying to reach half-way through the process of potting a particular plant, then the pot snaps in two, and the work has to be repeated. When this has happened a few times to the operator the importance of using sound pots is forced upon him.

A plant intended to be transferred to a larger pot should be in a medium state of moisture, neither too wet nor too dry. If the plant to be potted is small the crocks at the base can be easily removed by picking them out from among the roots. Large plants, when turned out of their pots, are usually very much pot-bound, with the roots entirely enclosing the drainage. The best plan with these, therefore, is to obtain a strong carving knife, cutting through the ball just above the line of drainage, thus detaching the crocks and reducing the height of the ball of roots, making it easier to place in the new pot. The compost specially enjoyed by the Azalea in its younger stages is two-thirds sweet turfy peat pulled to pieces (not chopped) and one-third loam of the same character. Add a fair proportion of white sand and broken charcoal, well incorporating the whole. For large plants peat and loam in equal quantities form the best staple materials, adding also sand and charcoal. The latter acts as a sweetener, and helps to retain porosity with the sand. When mixing it is desirable to have the compost in a healthfully moist condition when used, though care must be taken not to have it too moist on account of the compression required.

Arrange the crocks in the pots very carefully, first placing over the hole or holes large pieces with a slightly concave face, which is placed downwards; over these a layer of equal sized pieces, then one of fine crocks. Perfect drainage is very essential, and it is not the amount used, but the carefulness in arranging that which is employed, which admits of water escaping freely, yet preventing the crocks being choked with soil. Finish the whole by placing a layer of turfy peat free from dust or small particles over the top layer of crocks.

The plant may then be introduced. If it prove to be too low in the pot, introduce some compost, making it firm; if too high, reduce the size of the ball by slicing off the bottom to the desired extent. I would not even hesitate to take off a few slices from the sides if necessary. Use judgment in this, however, as it is inadvisable to destroy a mass of healthy roots if it can be avoided. Sufficient room must be left above the surface of the ball and below the rim of the pot to admit some fresh compost and leave room for watering. Having adjusted the ball of roots properly, proceed to introduce the compost equally all round, ramming each layer down firmly with the blunt end of a potting stick. Fill in more, and treat in the same way until finished. The new compost must be made as firm as the old ball. This is important, because if left looser the water will pass through the new soil without penetrating the old. It is absolutely necessary that the soil is made firm, fine hair-like roots, such as Azaleas have, always needing a firm medium.

After potting stand the plants in a moist, shady temperature, syringing them frequently, but not giving any water for some days. A supply may then be given of the same temperature as the structure in which the plants are growing, giving enough to moisten the whole. No more ought to be required then for some time. The daily syringings will keep the plants moist and encourage the production of new roots. As the growth proceeds and approaches completion more air must be given, and when the foliage is sufficiently hardened and the buds begin to set, the plants should have the coolest and airiest position possible under glass, finally moving to a sheltered place outdoors to fully perfect and ripen the growth. See that newly potted plants do not become saturated with moisture when outdoors. If there is any risk likely in this respect it would be best to keep them in a cool house or frame, or where protection can be afforded during more than usually wet periods. Finally house the plants in September, placing them in a cold house where abundance of air is admitted, so that they are kept completely at rest.

I will next refer to the treatment of established plants in pots, such as have not been repotted for some years. After the flowering period is over in the spring or early summer clip away all the flower stalks without damaging the young growth. Unless it is desired to have the plants in flower earlier another year, no special treatment is necessary to forward the growth which may be made in an ordinary greenhouse, occasionally syringing the plants to aid growth, and to refresh and cleanse them from dust, as well as avoiding attacks of red spider and thrips. When the growth becomes mature, which will be

in July, take the plants outdoors, standing them in a favourable position on a bed of ashes, protecting also from cold rough winds. Watering must be strictly attended to, examining the plants frequently to ascertain their condition, affording an adequate supply when the necessity arises, which sometimes will be every day, at other times several days may elapse without watering.

Before the plants are housed it is desirable that they be examined for thrips, this pest attacking the foliage, chiefly on the under sides, and doing much damage if not checked. This insect abstracts the juices from the leaves, discolouring them, and causing their fall, thus leaving the plants bare and unsightly. Thrips may be destroyed by dipping the plants in a solution of softsoap, 2 or 3 ozs. to the gallon of water. If dipping is not possible owing to the size of the plants, lay them on their side and syringe every part thoroughly.

The best time to commence forcing the Azalea is about the middle of January, choosing the white varieties for the purpose. The semi-doubles are best for cutting. *A. amœna* is one of the best for the earliest forcing, and may be started in December. *Deutsche Perle* is a double early, and blooms with scarcely any forcing if the growth has been made early. *Narcissiflora* is almost a constant bloomer. *Alba sinensis* is also a good forcing variety and one of the oldest. Other good varieties are *A. Borsig*, *Stella*, *Pauline Jardine*, *Beauty of Surrey*, *Admiration*, white, with crimson flakes; *Baco de Rose*, a double flower, and *Flower of the Day*, beautiful clear white, striped with rose. There are numerous other varieties, indeed it is scarcely possible to grow a bad variety of Azalea.—E. D. S.

NAMES AND KINDS OF CARNATIONS.

(Continued from page 162).

THE earliest literature of the Carnation introduces us to a flower already divided into sections. Dodoeus provides engravings of a large single flower, and of a small and a larger double bloom. The flowers were white, light purple, deep red, shades between white and purple, and versicolor varieties. In Steven's and Liabaud's (1586 ed.) "*La Maison Rustique*," the colours are not given; but the no less interesting information is accorded that varieties were numerous, of which the best were broad, tufted, and full, also cultivated with much care. These were called Provence Carnations. A section composed of varieties with smaller flowers, which were less sweet, received less generous treatment, and were called Rosette Carnations. The forerunner of yellow varieties appeared in England shortly previous to the close of the sixteenth century, and a few years later the now all but unknown "*Painted Lady*" made its appearance.

The earliest notice of the Picotee that I have seen is in 1650, when it is described by J. Bauhine as a white flower thickly and evenly spotted with blood red. In 1792, as described by Maddocks; it is still spotted. "The colours," he remarks, "are principally yellow and white spotted; their properties are the same as the other kinds (Carnations), except that the edges of the petals are serrated or jagged, and the colour is dispersed in spots where the others are striped." Phillip Miller states that "Picquettes are spotted (or pounced as they call it)." Though Picquettes were very popular, no change appears to have taken place in the form and quality of the flowers till about the end of last century. However, during the first thirty or forty years of the present century the transformation of the flower was rapid and complete.

We find the evolution illustrated in coloured drawings of the period. Thus in "*The Temple of Flora*" (1803-12) two Picquettes are shown, one with petals roughly marked on the edges, the other much like a fancy Picotee of the present day. A pretty, but rough, edged Picotee appears in the second edition (1810) of "*Maddocks' Florists' Directory*," and in "*The Floricultural Cabinet*" for 1835 a heavy scarlet-edged variety, with deep yellow ground, as well as a light-edged white flower, is printed. Both blooms are in ground colour quite pure, and the marking of the edges clearly defined.

In 1839 a large purple-edged flower named *Dr. Horner* appears, and the various distinctions by which the edged Picotee is known at the present day had then already been made. The second edition of Hogg "*On the Carnation*" (1822) contains a coloured plate of a yellow Picotee with petals full of deep serratures, twisted and splashed on the yellow with many colours. Hogg's plants at this time were imported from the Continent, and this plate is extremely interesting as showing the kind of flower cultivated at this period in Germany, France, and other Continental countries. It is noteworthy that the Picotee has reached us in an unbroken line of descent from its beginnings in the seventeenth century. Yellow grounds appear to have been popular only by fits and starts, and the finest forms of these as well as self-coloured yellows existed from about 1830 to 1840. In Glenny's list for 1844 they are not mentioned at all.

"Painted Ladies," like Picotees, continued for nearly two centuries

without much if any change, when they suddenly disappeared from cultivation. I first saw one about twenty years ago, when a plant named "Parkinson's Painted Lady" came into my hands. It did not live long. Later I had three varieties from the North of Ireland, none of which, however, were worth growing; but from among a number imported from Germany a kind named "Meta" has proved one of the sweetest and best of border Carnations. The "paint" in this variety is red.

The classes in which the greatest interest centres are, however, the flakes and bizarres. It is by no means improbable that the "streaked Gillyvors," which Perdita refused to plant in her garden were the earliest forms of these and possibly Belgian "versicolors." On the Continent their cultivation must have been pursued with great zest, for towards the end of the seventeenth century Gilbert notes that "the nobler sorts which are called Dutch Julyflowers were raised from seeds in the Netherlands, and thence conveyed to us." These on account of the size and conformation of the flowers obtained the names of "Magnum Bonums," of "Monsters," and of "Bursters," the last being the usually applied designation. On the Continent single blooms were grown up to 7 inches across, but in England a bloom measuring 5 inches in diameter was considered worthy alike of commendation and of emulation.

These were classed respectively as Beazards, with white ground, spotted and barred; Flakes, of two colours, regularly striped; and Flames, with a red ground, ribboned with black or purple. In Bursters the blooms were peculiar in being composed of two flowers, the one closely superimposed on the other. In Souvenir de la Malmaison we have a variety that sometimes approaches very closely to these old forms, when strongly grown flowers are occasionally produced provided with a double calyx, and with two distinct blooms in one, and these abnormal types always expand into flowers of an exceptional size.

"Bursters" were allowed to carry only one bloom to each plant, for, as an old writer remarks, "It is not how good, but how big is your Flower;" and "Reason teaches that one Flower will be better fed from the Root than many." Much care was expended on slitting "pods," and strengthening those with vellum or oilcloth which in places had burst beyond bounds. The petals were carefully drawn forward, and the inner calyx manipulated, so that a bloom of "noble proportions" should be the result.—R. P. BROTHERSTON.

(To be continued.)

HARMFUL AND HARMLESS GARDEN MOTHS—17.

SOME of the good old entomologists gave to one group of English moths the funny title of the "rustics." In their habits they are not particularly rural. Several frequent fields, but other species occur about gardens, and may even turn up in the immediate neighbourhood of a town or city. One of the commonest, and also a particularly injurious species of *Noctua*, is a rustic moth, which possesses the name of the rustic shoulderknot, *Apamea basilinea*. The former name seems to have arisen from a fancied resemblance between a mark upon the fore wings and the porter's knot, which was commonly to be seen about London streets in the time of George III., when burdens were usually carried on the shoulders, barrows and trucks being less frequent than they are now. A black elbowed line upon the ochreous ground suggested the Latin name.

Both sexes occur about garden flowers at midsummer and after; the female moths then resort to the corn fields, depositing eggs on the half-ripe ears. The young caterpillars secrete themselves in the lower part of the stalk and feed upon the grains till they harden. Of course they are carried to barns and granaries with the corn, and are sometimes found in such places by thousands. Wandering off, each little caterpillar makes a cocoon somewhere, within which it sleeps till spring arrives. Then they change their habits, and feed on various low plants about fields, gardens or hedgerows, resting on the soil by day. About the end of March or in April we may find them full-fed caterpillars with pale shining heads and stout bodies, which are darkish brown, having some black spots, and a yellow line down the back. Afterwards they enter the earth to assume the chrysalis state.

Several species in the genus *Apamea* live as caterpillars upon grasses or their roots, preferring fields to garden lawns, though the moths visit gardens for sweets if obtainable. One of these is the moth called the common rustic, *A. oclea*, a very variable insect, difficult to make out even to an entomologist. It is some shade of brown, with indications of a darker band; the white spot, which the Latin name indicates, is often wanting on the fore wings. Its caterpillar is putty coloured, and feeds during the spring on grasses, being fond of the species of *Poa*. The larger and handsomer dusky brocade moth (*A. gemina*) has two varieties; one has a couple of conspicuous spots of grey on the dark brown wings, the other has the wings lighter, and the spots are wanting. It occurs throughout our islands in July. The

caterpillar feeds first in autumn, then again from March to May, upon grasses, specially the canary kinds, *Phalaris*, sp., if accessible. Also handsome and singularly marked is *A. ophiogramma*, or the double-lobed; the grey wings are festooned with brown, in which colour is enclosed a double spot. This moth is captured frequently about London suburbs; and, though the caterpillar can live on grasses, it sometimes burrows into the pith of the common garden Flag, and very probably causes the decay of other species of *Iris*. We look for it during spring, and the moth emerges in summer.

A rather abundant June moth is the pale mottled willow, or *Caradrina cubicularis*, a dull coloured insect, which has nothing to do with the Willow that I am aware of, and its scientific name seems to have caused a curious blunder, for the author of a list of moths remarks it was apparently so called because it is found in bedrooms or out-houses. Like some other moths, it may sometimes hide in a room when it wishes to rest, but the name, most likely, arose from the caterpillar's habit of making itself a little apartment in which the winter is passed. The eggs are laid upon cereals and leguminous plants, Wheat, and Peas in fields, being chiefly selected by the females. When the crops are harvested the young caterpillars go with them, and where they are laid up, form these abodes, out of which they emerge in early spring to feed again upon the grain or pulse, if stored. Therefore the species is one that, owing to its destructive habits, we are justified in killing should we have the opportunity.

Of moderate size is the moth called the brown rustic, or *Rusina tenebrosa*, certainly a shady species as the name implies, though the dark wings are of a rather lustrous brown, crossed by two zigzag black lines, and having a few pale spots we do not see unless we examine closely. It is a June moth, not rare in most English counties, and its appearance about gardens is explained by the occasional food of the caterpillar, which lives from August to April, feeding at intervals through the winter. Along fields and waysides we may detect it upon chickweed and knotgrass, but some seasons it is found in gardens upon species of *Viola*. This insect keeps well below its food plants during the day, hiding amid particles of earth and stones, but at night it devours the leaves or gnaws the stalks. In shape it is peculiar, narrowing towards the head and tail, being, therefore, somewhat like a shuttle; it has a velvety skin, puckered along the sides, the body is brown, marked with grey.

We pass on to an important group of moths known in their early stage to all gardeners; but the species generally are puzzling to make out, the colour and markings of many of the moths being much alike; nor, even if reared, do the caterpillars help us to identify, as they often are very similar. Several of them take a place on the black list as insects which damage our crops. The moth, inappropriately called the dark sword grass, or *Agrotis suffusa*, may be seen among flowers in September, then hibernates, flies again, and deposits eggs in April, after refreshing itself with spring sweets. It is some tint of brown, varied with grey spots and lines, the under wings pearly and pinkish. Hatched in May, the caterpillar lives upon a variety of garden plants; it has been taken feeding on the roots or leaves of Lettuce, Spinach, Seakale, Radish, and other vegetables. By day it is unseen, feeding then under the earth; after dusk it emerges to attack the plants above ground. It is a slate coloured caterpillar, rather shining, dotted over with small warts; from each of these rises a hair. The cell in which it becomes a chrysalis is compact, and the interior carefully lined.

The Turnip moth (*A. segetum*) is a dull looking insect; its sober tints and moderate size are not suggestive of mischief, but the caterpillar is a persistent and artful foe, not much behind that of the Cabbage moth in destructiveness. Their season of emergence is June and July, and in going out with a lantern amongst vegetables at night we may detect the females busily engaged in depositing eggs. They are usually placed close to the ground, upon some seedling by preference, which the young caterpillar nibbles persistently and frequently kills.

Turnips may be a favourite article of food with the species, but anything succulent is acceptable. Carrots, Cabbages, and other vegetables are victims to its jaws, nor does it spare some ornamental plants. Newman refers to its visits to the China Aster; he says, "The leaves of a plant will be found to be withering and curling up, examine the stem where it enters the ground, and you see it is nearly decorticated, the circulation of the sap is prevented, and growth stopped. You pull up the plant to find the enemy, but fail; he has wandered many inches away, burrowing in the earth like a mole." This entomologist also remarks upon the utility of certain birds, such as the rook, starling, possibly even the much-abused sparrow, which devour the caterpillar, or take it to their young. After feeding through the summer, it changes the mode of life, and keeps almost entirely under ground, subsisting upon the roots or tubers of plants, and continuing to eat, unless very cold weather sets in, when it remains torpid. About May we find it adult, a stout caterpillar then, small-headed, a horny plate on the second segment, and dotted over with shining spots, in colour grey.—ENTOMOLOGIST.

ODONTOGLOSSUM WILCKEANUM PITTE.

IN our brief report of the meeting of the Royal Horticultural Society, on the 8th inst., we referred to the general excellence of the Orchids shown. Amongst the most conspicuous was *Odontoglossum Wilckeanum Pittæ*, which received a first-class certificate from the Committee. It is one of the handsomest varieties that has ever been seen, and the plant is of peculiarly robust habit. The large flowers, of which there were seventeen on the spike, were of great substance, and the well known colour markings are all much improved upon. It was shown by H. T. Pitt, Esq., Rosslyn, Stamford Hill, and is depicted in the woodcut (fig. 51).

ORCHIDS AT CLEVELEY, ALLERTON, LIVERPOOL.

I HAVE on several occasions mentioned various Orchids seen in flower at Cleveley, but *Lælias* and *Cœlogynes* make the handsomest display, the former being in full beauty in November, and from that time until the wane of the *Odontoglossums*, there will, for more than six months, have been a veritable wealth of beauty. But it is of the present time that I want more especially to speak, as *Cœlogyne cristata* and its varieties have been delighting many visitors.

Nothing surpasses them for beauty in the earlier spring months, and I have seen them on previous occasions, as I thought, almost perfect, but the crowning success in flowering seems to have been reached this year. Mr. Cromwell, Mr. Timmis' esteemed gardener, attributes this chiefly to the thorough ripening of the pseudo-bulbs in the autumn of 1897, the prolonged sunshine having had a marked effect. Every bulb of last year is producing its spray of flowers. A space 20 feet by 9 is taken up with the plants, a background of Palms and Ferns completing a picture of a beauty not easily forgotten. There are in all eleven plants, averaging 3 feet in diameter, each pan having an average number of 100 spikes, the highest number of flowers on a spike being eight, and it is interesting to note that these are found on the *Trentham* and *Chatsworth* varieties. *Maxima* and *Lemoineana* follow with seven, the ordinary varieties having from three to four. This clearly shows that the first two varieties should be sought after by cultivators.

Arranged in the same house are other good and useful Orchids, such as basket of *Dendrobium Ainsworthi* carrying 300 flowers, *D. Leechianum*, *D. albiflorum*, *D. crassinode Barberianum*, the lovely *D. Cassiope*, *D. nobile cœrulescens*, *Cypripediums* in variety, and *Cattleya Trianae*, which all go to swell the list of beauty, form, and colour so noticeable amongst Orchids. *Dendrobium nobile*, *Cymbidium Lowianum* and *C. eburneum*, the latter, often found so difficult to grow, are promising a rich harvest of bloom, and are to follow the *Cœlogynes*. I may, perhaps, be pardoned for mentioning in this column the beautiful corridor. It is just now brilliant with Azaleas, spring bulbs and Roses, whilst handsome bushes of that capital forcing *Rhododendron*, *Madame Wagner*, are especially striking.—R. P. R.

TEN MINUTES' NOTES.

HITHERTO my pen has been prone to touch on wide and various items at random as entering my mind first. I now send a few notes appertaining to fruit and fruit trees as a more united contribution.

BLENDED FRUITS.

Not regarding myself an old fashioned, or, on the other hand, one of your "new fangled" gardeners, I can safely ask, what on earth do we want with such anomalies and mixtures as the following? A "white" (?) Black Currant, a Raspberry-Strawberry combination, a Gooseberry with a smack of Black Currant thrown in as a flavouring, and so on. I see no useful purpose to be served in these eccentric fancies of a few novelty specialists. They are not "made in Germany," for a wonder, but emanate principally from over the "herring pond." If we are to have a "blend" by all means consult a cookery book, and render the cook a service by raising some such fruits as a mixture of Raspberry and Red Currant, Blackberry and Apple, or Rhubarb and Orange, which, by the careful incorporation of their substances in due proportion, would result in universal praise in the kitchen, and, perhaps, save us from unknown jam mixtures now so prevalent.

TRAINING PEAR TREES.

By this I am referring to what should be the mean space between the branches, taking an horizontally trained specimen first. With most varieties every third joint—i.e., from 14 to 15 inches, would seem a fair distance, so as to allow free circulation of light and air amongst the foliage, and the fruit to hang clear of obstruction; but this space would

hardly suffice for some others that assume a more straggling habit of growth, such as, say, *Marie Louise*, or *Beurré Rance*, or with large foliage as *Beurré Diel*; then four bricks space is necessary to insure good results. With fan-trained trees this regularity or uniform space is of course impossible, as at the base an inch or so apart develops into a foot or more at the extreme end of the branches; it is better to err on the side of wider spaces than attempt to crowd the branches in any sense. When training maidens select those side shoots which point straight to the space desired, those on both sides to be evenly balanced and level. The tree looks unsightly with one bough bowed down and the other bent upwards to get them into anything like good shape. It will be almost a necessity to head back the leader every year, selecting as near as possible two side buds to form branches, and one at the apex for a leader. In all probability the side shoots will not be of equal strength; in that case the stronger one will need pinching to induce the weaker one to make headway with the increased supply of sap resulting from that operation.

BRAMLEY'S SEEDLING APPLE.

Without doubt this Apple is one of the best kitchen kinds in cultivation, and I do not know if I should be committing an act of piracy in using its raiser's eulogy on its merits as "the finest Apple on earth." Mr. Merryweather has more than once told me of the yearly increasing sale until the demand for "Bramley's" is enormous. I have frequently

FIG. 51.—ODONTOGLOSSUM WILCKEANUM PITTE.

seen specimens grown by cottagers or small holders weighing 25 and 26 ozs. I know a man of the latter class who generally manages to pay his rent with the sale of his "Bramley's." Some years he has several hundred pecks, which he holds in reserve until the glut of Apples is over, when the lowest price asked is 2s. 6d. per peck. This is cheerfully paid at Christmas time on account of the firmness and quality of the fruit when used in mince meat. A garden without its Bramley's Seedling in Notts would be hard to find, and other counties are fast following suit. One of its characteristics is its late flowering habit, which usually tides it over the May frosts. Sturdy growth enables it to be self-supporting. It is, perhaps, not quite so quick as some varieties in reaching its bearing period; but when once established it recoups all this, and outclasses most of the older kitchen varieties. Beyond procuring young trees it is economy to cut down and graft worthless varieties with this very hardy and serviceable Southwell Apple.

Re FORMER NOTES.

I beg to thank Mr. Geo. Abbey for replying to my queries so fully I find I am in error as regards the *Cineraria* grub, and the larvæ of the Celery fly, which latter I have found dislikes sprinklings of soot on the leaves on dewy mornings. I hope to make a closer observation in due course as regards these pests, and if possible adopt a preventive. With flned garden walls, the last paragraph hits the right nail on the head (page 148) as presenting the only sound principle of "utility with economy." No doubt Apricots were mostly benefited by the old system, on account of the protection necessary by their early flowering. I, however, feel gratified to have the personal experience of Mr. Abbey. It enhances the interest of these old-time appliances from a practical point of view, and not mere conjecture. Only this morning I came across some old volumes of the *Journal*, dating back, in the case of the one I opened casually, to 1868, or thirty years ago. I was pleased to note two names as contributors then that are still to the front—viz., "D., Deal," and Mr. Geo. Abbey. Long may they continue to record their valued experiences for the benefit of many readers of the popular *Journal* of the present day.—GEO. DYKE, *Stubton Gardens, Newark*.

ROSE SHOW FIXTURES IN 1898.

- June 15th (Wednesday).—York.*
 „ 16th (Thursday).—Colchester.
 „ 23rd (Thursday).—Bath (N.R.S.).
 „ 25th (Saturday).—Windsor.
 „ 28th (Tuesday).—Southampton† and Sutton, Westminster (R.H.S.).
 „ 29th (Wednesday).—Canterbury, Croydon, and Richmond (Surrey).
 „ 30th (Thursday).—Eltham, Gloucester, and Norwich.
 July 2nd (Saturday).—Crystal Palace (N.R.S.).
 „ 5th (Tuesday).—Harrow.
 „ 6th (Wednesday).—Farnham, Hanley† and Redhill (Reigate).
 „ 8th (Friday).—Ulverston.
 „ 12th (Tuesday).—Wolverhampton.*
 „ 13th (Wednesday).—Newcastle-on-Tyne.*
 „ 14th (Thursday).—Halifax (N.R.S.), Canterbury (Hospital Fund), and Helensburgh.
 „ 26th (Tuesday).—Tibshelf.

* Shows lasting three days. † Shows lasting two days.

The next list of fixtures will appear early in April. In the meantime I shall be glad to receive the dates of any Rose shows, or other horticultural exhibitions where Roses form a leading feature, for insertion in that list.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

ROSES AT FRANKFORT.

WE are informed that a great exhibition of Roses is to be held at Frankfort during the ensuing season—the largest, its promoters hope, that has ever been held on the Continent. The exhibition is to be opened early in June, and to be continued throughout the season.

SUNRISE.

THIS is the expressive name of a very beautiful new Tea Rose, raised by Mr. A. Piper. Its colour is highly attractive—a combination of bright apricot yellow and metallic red. It is even lovelier in the bud than *Beauté Inconstante*, and opens with much greater facility. The raiser tells me that it is his earliest-flowering Rose; that it is a vigorous and abundant bloomer. It is a splendid companion for *Enchantress* and *Empress Alexandra of Russia*.—DAVID R. WILLIAMSON.

STANDARD ROSES.

ALTHOUGH not nearly so much grown as was the case a couple of decades ago, there are still many persons who prefer their Roses in standard form. Certainly a well grown standard has a better effect upon the lawn than the ordinary dwarf; but how often we see merely a stick with a top like a worn-out broom. Such a plant, I venture to say, is far from an ornament.

If we are to have standard Roses with any show of beauty, or prospect of more than a couple of years' life, it is absolutely necessary to select varieties of very free or of vigorous growth. One cannot reasonably expect a dwarf or indifferent grower to make a good head on a bare stem 3 feet or more from the ground. Even as dwarfs they do not make much headway. How, then, can they derive sufficient sap when it has to be drawn from so comparatively great a distance? Nor is this all. We are constantly cutting off the suckers of the Briar stock, and the weakly growing Rose at the top is not sufficiently active to keep the Briar healthily alive, and hence both rapidly fail.

But when we grow such as *Duke of Edinburgh*, *Madame Gabriel Luizet*, *Gloire de Dijon*, *Rêve d'Or*, and *Crimson Rambler* in this form, it is seldom we fail, simply because such varieties are strong and vigorous enough to command and make use of the sap the Briar would naturally supply. Our free growers are also able to thrive on tall stems, as they are constantly pushing out a succession of new growths, and will not be denied. *La France*, *Viscountess Folkestone*, *Augustine Guinoisseau*, *G. Nabonnand*, *Marie Van Houtte*, *Boule de Neige*, and *Françoise Kruger* may be given as examples.

Do not attempt the weaker growing Roses, such as *Horace Vernet*, *Louis Van Houtte*, *Cleopatra*, *Comtesse de Nadaillac*, and others as standards. I am aware that many do so, in the hope of keeping such grand and heavy blossoms from being soiled through summer showers. If grown on the hedge Briar stems at all, let them be from 12 to 18 inches long.

There are few if any prettier ways of growing *Rêve d'Or*, *Blairi No. 2*, *Madame Bérard*, *Reine Marie Henriette*, *Crimson Rambler*, and others of extra vigour, than as tall standards from 5 to 6 feet. The long rods of the previous summer are arched over, and flower through their entire length, forming a perfect half globe of great beauty. These varieties bloom very freely, and at one time, so that the effect is grand. Our Persian and Austrian Briars are best upon short standards of 2½ to 3 feet, when their slight wooded growths arch over very naturally with the weight of blossom and foliage.—P. S.

VIOLETS IN COLD FRAMES.

IN the Violet we have a flower that is always in great demand, and if the grower has a few cold frames he can readily have flowers from his plants throughout the winter and spring months. As it is a plant that is not difficult to grow, it behoves every gardener to do his best to insure an almost unlimited supply. One often sees frames filled with miserable plants with scarcely a leaf or flower bud on them, a state of things far from satisfactory when we consider how easy it is to have them growing and flowering freely. When the plants are in this condition it is a sure sign that they have been coddled, or were allowed to get dry at the roots during the previous summer and have been eaten up with red spider, causing a wholesale damping of the leaves when the plants were put in the frames.

The Violet being hardy requires no heat to grow it. Where, however, the convenience exists to maintain a temperature of 45° with air on at all times, it greatly assists the flowers to open during severe weather. The winter that is just past has been an exceptional one for the Violets growing in cold frames, as it has scarcely been necessary to cover the frames with mats, and the plants have flowered abundantly.

Now is the time to think about the plants for another season, and I will endeavour, in as clear a way as possible, to give the cultural details as carried out by myself, in the hope that it will benefit others. Where a stock of plants already exists, the beginning or middle of March is a good time to give them a top-dressing of loam and leaf mould, working it well in between the plants. This having been done, give a watering through a coarse rose, as it will settle the mould amongst the crowns, besides washing the leaves and flower buds, and by the middle of April they will have made splendid rooted runners, which, in my opinion, are far better than taking cuttings. The old plants are then lifted, the rooted runners removed with a sharp knife, and planted out on a north or east border which had been previously prepared by having a dressing of leaf mould and road grit dug into it. I plant 9 inches apart in rows a foot asunder, as this allows room to keep the soil stirred between them during the summer. The plants must never be allowed to get dry at the roots, or red spider will very soon make its appearance on the leaves, and once it gets a hold, it is very difficult to eradicate, and besides giving the plants a serious check, it causes the leaves to damp badly when the plants are placed in the frames in the autumn.

At the beginning of September the plants are carefully lifted and placed in frames that have been partly filled with all kinds of garden sweepings, on which about 9 inches of equal parts loam and leaf mould is spread, so as to bring the plants to within about 6 inches of the glass. A thorough watering is then given, the plants are syringed for a week or two, by which time they will be growing freely again. It is the practice of many growers to keep the frames close for a few days after planting; but I prefer a slight syringing to encourage fresh growth, and never put the lights on the frames until severe weather makes it a necessity. The plants should occasionally be carefully looked over, and any leaves showing signs of decay immediately removed, or much harm will be done, especially during bad weather, when the lights have to be kept on. *Marie Louise* I consider far the best Violet for growing in frames. Never allow plants to become dry at the roots, syringe frequently during hot weather, and afford plenty of air.—G. HART.

HEATING WATER IN TANKS.

IN the correspondence columns of the issue for March 3rd I notice that information is given on the above subject. It is one of some importance, as the advisability of watering plants with water of the same temperature as the house is patent, particularly during the winter months.

The greatest difficulty, however, is that of taking the chill off a body of water, and this can be obviated at the time of laying hot-water pipes and making tanks by arranging in such a manner that a pipe flows through or round the inside of the water receptacle. The constant presence of the heated pipe takes the chill off the water, and renders it suitable for applying to plants. The amount of piping in the tank must be governed by its size, for if there is not enough the warming influence will not be sufficient for a large body of water; and if, on the other hand, there is too much heating power, the water will form vapour, and this of course would be detrimental to the plants. This method of warming water is excellent in early vineries and Peach Houses, where a quantity is required for the borders during the opening months of the year; and when the pipes are run through the tank in the first place much trouble is afterwards saved.

There are several drawbacks in the way of heating water in tanks from the pipes. In the first place, if the tank is large it would take a large body of hot water to effect the purpose, and it is obvious that drawing the greater part of the hot water from the pipes means a lowering of the temperature, and this in cold weather is a consideration. Secondly, if the pipes and boiler are not kept constantly flushed rust accumulates rapidly, and discolours the water drawn therefrom. Where such is the case to an advanced degree it would not be to the welfare of tender plants to water with liquid contaminated in such a way. In these and other respects the advantage of heating water in tanks by running pipes through them is seen.—G.

[The reply alluded to was given to a correspondent who desired to have slightly warmed water in the absence of pipes in the tank.]

WEATHER IN LONDON.—The latter half of last week was characterised by the dry, bitterly cold winds that prevailed the whole of the time until Saturday evening, when it was slightly foggy. On Sunday morning the fog remained, and was accompanied by a moderately sharp white frost. The later hours of the day were clear and cold, but with very little wind. Monday was wet until late in the afternoon, when the sun shone brightly for a short time. It was warm throughout the day, and the change from easterly wind continuing. Tuesday was warm and dry until the evening, when rain fell. Wednesday was dull, but warm.

WEATHER IN THE NORTH.—The past week has generally been fine, and there has been no frost except a slight touch on the mornings of the 9th and the 13th. A spring-like feeling has frequently pervaded the air. The afternoon of Sunday was cold, and the evening and night were very wet, but Monday was throughout dry and pleasant, with a rather high S.W. wind. Tuesday morning was very showery, with the thermometer at 43°.—B. D., *S. Perthshire*.

NATIONAL FLORAL SOCIETIES.—We are glad to see from the twenty-first annual report of the "National Auricula and Primula Society" that there was a large accession of new members last year, and that the financial position of the Society, which was sound before, has been consequently strengthened. This year's show is to be held in the Westminster Drill Hall on April 26th. The "National Carnation and Picotee Society" (southern section) has also attained its majority, and is in a highly prosperous condition. The members number 350, including an addition of seventy-eight during the past year, and there is a financial balance in favour of the Society of upwards of £208. The exhibition is to be held at the Crystal Palace on July 20th.

WIMBLEDON HORTICULTURAL SOCIETY — PRESENTATION TO MR. H. THOMSON.—At the twenty-fifth annual meeting of the above Society, held on the 9th inst., a well-deserved mark of esteem was presented to the diligent Secretary, Mr. H. Thomson. The presentation consisted of a nearly life-size portrait of himself, prepared by Messrs. Russell & Son, and was quite life-like in character. It bore the following inscription:—"Presented by the Officers and Committee of the Wimbledon and District Royal Horticultural and Cottage Garden Society, as a mark of esteem and respect and in recognition of twenty-five years' valuable service. March, 1898.—Thomas E. Crocker, President." Mr. Crocker, who is a strong supporter of the Society, the shows of which have of late years been held in his grounds, tendered the gift in felicitous terms, and the recipient's acceptance of it was not less appropriate. Mr. Thomson is a local nurseryman, and his excellently kept grounds must have been admired by many travellers on the London and South-Western Railway between Wimbledon and Surbiton. The next show of the Society is to be held, by kind permission of Col. Mitchell, who was present at the meeting, in the grounds of Cannizaro House, on the confines of Wimbledon Common.

THE CLEAR WAY.—It is not often that gardeners' powers of explanation are brought into question, though "An Old Reader," on page 192, seems to think there is room for improvement in this respect. He is gratified to note that owners of small gardens are becoming enlightened on the difficulties with which gardeners have to contend. It would perhaps be well for gardeners in many cases if owners of large establishments would also acquire that knowledge, as it would tend to alleviate the worries experienced in the endeavours to make all ends meet. I gather that "An Old Reader" wishes to see gardeners masters of language, and would have them endowed with powers of conversation by which they can prove to complaining masters and mistresses why this plant is "leggy," and that one refuses to flower. The logic is doubtless good where ready listeners are to be found to such explanations, but there is a danger of it being extended until the acquirements which your correspondent would encourage are used for the framing of excuses. Genuine explanations on the part of gardeners are often misconstrued, and are accepted only as agitations for additional outlay, and this is unfortunate. On the other hand, the incapable gardener is often a profuse explainer, or rather let us say excuse maker, and in this respect your correspondent touched on a question that has two distinct sides.—H.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, March 22nd, in the Drill Hall, James Street, Victoria Street, Westminster, 1 to 5 P.M. A lecture on "Soils" will be given by Mr. J. J. Willis, at 3 o'clock.

HORTICULTURAL CLUB.—The usual monthly dinner and conversation was held on Tuesday, the 8th instant, when the chair was occupied by Mr. Harry J. Veitch. A valuable paper was read by Mr. J. A. Gammie on the Cinchona in India, in the culture of which he had been engaged for many years in the Bengal Presidency. An interesting discussion followed.

NARCISSUS MINOR.—This charming little Daffodil, which is among the earliest of the genus in average years, is at present in full bloom. For the front of the border or rockwork it will be found one of the best, and good clumps please all with their bright yellow trumpets and perianths. It thrives exceedingly well in this district, and nowhere seems happier than in light soil. There is a white variety, but it is rare, and seldom offered in catalogues, and appears to be somewhat tender. Although *N. minor* is scarcer and higher in price than *N. nanus*, it is a better doer in my garden, although this is not usually the case.—S. ARNOTT.

MIDLAND CARNATION AND PICOTEE SOCIETY.—The seventh annual report and balance-sheet of this Society have just reached us, and a perusal of them proves that the condition of affairs is extremely satisfactory in all respects. The 1897 Show, held at Edgbaston, was greatly superior to any of its predecessors, the number of exhibitors having materially increased, while the quality of the blooms was remarkable. We observe that the schedule for the present year's Show comprises rather over fifty classes, amongst which a sum of £185 is distributed. In several of the classes as many as seven prizes are offered, and in these there will not in all probability be many disappointed exhibitors. The Hon. Secretary of this admirably managed Society is Mr. H. Smith, Tenby Street, Birmingham, to whom communications ought to be addressed.

BIRMINGHAM GARDENERS' ASSOCIATION.—"A Chat About Orchids" was the interesting subject so graphically discoursed by Mr. H. A. Burberry at the usually fortnightly meeting on the 7th inst. Mr. W. B. Latham, Botanical Gardens, Edgbaston, was in the chair. The lecturer's remarks were principally confined to the cultivation of those species and varieties adapted for general purposes as will flourish amongst ordinary greenhouse plants. Special reference was made to the feeding of Orchids, the essayist entertaining considerable doubt as to the necessity of applying manure in any form. He was not an advocate for heavy applications of the syringe, but more for "dewings." For the perfect maturation of the pseudo-bulbs of some species a free circulation of air was advised. The much-controverted practice of pruning away the old pseudo-bulbs, especially of *Dendrobium nobile* and its allies, was also an item which he was not antagonistic to, though he would not advise the system, unless in the hands of an expert. An interesting discussion ensued, and a hearty vote of thanks was accorded to Mr. Burberry.

CHESTER PAXTON SOCIETY.—At the usual fortnightly meeting of this Society Mr. G. P. Miln, Hon. Sec., delivered a lecture on "Sir Joseph Paxton." By way of introduction Mr. Miln mentioned that there had never been any complete biography published of Sir Joseph, and it was not without some difficulty that a life history of him had been obtained. This prince of gardeners was described by the lecturer as one of the great men of the century; and his career was minutely traced from the time he became an apprentice-gardener to the period when he was returned member of Parliament for Coventry. His great work at Chatsworth, his valuable contributions to botanical and horticultural literature are well known to gardeners generally. But the crowning effort of his life was undoubtedly the designing of the building in Hyde Park, in which was held the great Industrial Exhibition of 1851, and which was afterwards reconstructed at Sydenham. For this he received the honour of knighthood, a well-earned distinction. The later years of his life were devoted to commercial enterprises of various kinds, and the development of railways, but he never lost that love of gardening which he had so studiously cultivated in early life. In proposing a vote of thanks to the lecturer the President of the Society (Mr. N. F. Barnes) said the members were deeply indebted to Mr. Miln for having got together such an amount of valuable information, which previously was practically unknown to them; and a request was made that the lecture should be published in pamphlet form.

— **HARDY FERNS.**—Moist and shady borders, where flowering plants do not succeed satisfactorily, may be attractively furnished with a few vigorous hardy British Ferns. Tall Ferns suitable are *Lastrea Filix-mas* (Male Fern), *L. dilatata* (Broad Buckler Fern), *L. montana* (Mountain Buckler Fern), *Athyrium Filix-fœmina* (Lady Fern), *Scolopendrium vulgare* (Hart's-tongue), and *Polystichum aculeatum*; while towards the front the dwarfer growers, including *Polypodium phegopteris* (Beech Fern), *P. dryopteris* (Oak Fern), and *Blechnum spicant* (Hard Fern) can be planted.—S.

— **BECKENHAM HORTICULTURAL SOCIETY.**—At the last meeting of this Society a very interesting lecture on "Orchids" was delivered in the Public Hall by Mr. H. Burberry, whose paper treated chiefly the method of cultivation. Afterwards an interesting discussion took place, and the questions put were all readily answered by the essayist. There were some fine specimens of Orchids shown by Mr. Potter's gardener and Mr. H. O. Crowther's gardener, which were greatly admired. At the close a vote of thanks accorded to the lecturer was carried unanimously, and on the proposition of Mr. Murrells thanks were passed to those members who so kindly brought plants.

— **THE HESSLE GARDENERS' SOCIETY.**—A meeting of the members of the above Society was held on Tuesday, March 8th, when Mr. J. T. Barker, Orchid-grower to W. P. Birkenshaw, Esq., West Hill, Hessle, gave a very interesting essay on "Cypripediums and their Culture." He described the first variety introduced into this country and the time of its introduction, also the habitats of the various species which soon followed. He gave the most suitable temperatures for the different varieties, also the composts, and mentioned one or two varieties which required special treatment. Mr. J. P. Leadbetter, when proposing a vote of thanks to the essayist, spoke of the admirable manner in which Mr. Barker had worked for the Society, and it was undoubtedly owing to his diligence and perseverance that it stood in so firm a position. Mr. Blakey showed plants in flower of *Cattleya Trianae*, *C. delicata*, and *C. Mossiae umbrosa*. Mr. J. P. Leadbetter, Tranby Croft Gardens, had some well-flowered plants of *Laehenalia Nelsoni*, *Dendrobium Wardianum*, *Cinerarias*, and *Hippeastrums*. The essayist showed some splendidly flowered plants of *Dendrobium nobile nobilius*, and Mr. Riley some very good *Cinerarias*.—G. W. G.

— **DEVON AND EXETER GARDENERS' ASSOCIATION.**—At the last meeting of this Society a paper on "Variety in the Flower Garden," by Mr. J. W. Moorman, Superintendent of Victoria Park, was read. The essayist, who is a Devonshire man, and was at one time in the gardens at Poltimore Park, expressed the opinion that the main charm in successful flower gardening was to secure as great a variety and succession of plants as was practicable. It should not be, as was too often the case, a mere flash of summer beauty, but a succession of beauties extending, as far as possible, the season of bloom over the greater part of the year, as far as our fickle and changeable climate would permit. It had been a too frequent custom to dig over roughly the flower beds after the summer occupants had become disfigured by frost. A remedy for this could only be accomplished by the introduction of plants of a hardier nature, and whose natural propensities for blooming coincided with the ranges of the different seasons. Thus, at least, two distinct and opposite styles of flowering and foliage were necessary—one embraced a large variety of hardy but charmingly effective early blooming plants, generally known as spring bedding, the other as summer bedding. Fashion governed in the flower garden nearly as much as in dress, and during the years from about 1870 to 1885 carpet bedding was in the zenith of its glory, and though it did not suit all tastes, it found many admirers. He therefore held to the opinion that a few beds might be planted in any garden without incurring much adverse criticism if the work was done neatly and the plants chosen for their decided colouring and lasting propensities. More pot plants were now used than formerly, and where such could be judiciously blended it made a wonderful relief, as well as added to the variety of the whole. After detailing many flowers giving pleasing effects, which were at the command of the gardener at the various seasons of the year, and to the manner in which they should be arranged, Mr. Moorman pointed out that moderation and simplicity were the essential principles that should be applied to the arrangement. Overcrowding must be avoided, and so must the opposite extreme. The main aim and object in variety was to connect seasons, so that while some flowers had done their duty and passed their best, others were only in the zenith of their beauty, and were affording warmth, light, and brightness, while the more precocious kinds were removed from the beds in order that they could be refilled for summer. A vote of thanks was accorded to the writer of the paper, and to Mr. W. Andrews for reading it.

— **PRUNUS CERASIFERA.**—In several places about the gardens at Kew large trees of this are making a fine show, every twig being wreathed with pure white blossoms. In one particular it appears to have an advantage over many other early flowering trees, as frosty nights affect it but slightly, if at all. For grouping in parks or planting at the back of a shrubbery as a protection for choicer plants it is very useful, while for an isolated specimen in a prominent position on the lawn or elsewhere its free-flowering qualities make it welcome. In some seasons good crops of fruit are produced, the fruit when ripe being about 1 inch in diameter, bright red, and sweet. The variety "atro-purpurea," better known as *P. Pissardi*, is a highly valued plant, its worth lying in the combination of its free flowering and ornamental foliage qualities.—W. D.

— **THE BUSY BOTANIST.**—The receipt of a copious work on the "Flora of Berkshire," from the Clarendon Press of Oxford, sets in motion a current of reflections, prominent upon which are some flotsam-and-jetsam-like particles of abashed self-respect in presence of the tremendous application represented by nearly 800 closely printed pages of botanical details, every quire of which might easily represent a month's wanderings, another month's verifying, and a third month's preparation for press. Busy men of the world lose themselves in an awed admiration for the monuments of solitary industry which books like this represent, and will place it on their shelves with a double object—to dip into it in the moments of leisure which every such harassed being hopes for when wealth has lost its charm and politics have worn themselves to shreds, and to find in the sight of it a bracing tonic for work when the demon of idleness asserts itself. The chances of success for the work are not lessened by the fact that it has missed the Jubilee year, and are sensibly increased by the good fortune of a permit for a dedication to her Majesty the Queen. The price is 16s. net, and the diligent author is Mr. G. C. Druce, M.A.

— **WONDERINGS.**—A Northern gardener sends a note for the W.P.B., but as the writer seems rather a "pawky chiel" his little effusion was first handed to the printers. The result is as follows:—"We are wondering where the 'Missus' is. We like her very much, and think about her 'crowning mercies' every time it rains after a spell of dry weather. We always thought the estimable lady hailed from the South, but think it was in her last article she let on that she is in the North. We wonder how far north?—not so far as M. Andrée, we hope! We were glad to see from 'Traveller's' last article that he is now clothed and in his right mind. We fancied he was clean gone. We would like another 'Resting Tour.' When in Edinburgh for a few days last October, in passing the North British Hotel one drizzly morning, we 'couldna' help speerin' to see if Mrs. Scribe was flattening her nose against the window in a brave attempt to see Auld Reekie." [Our imaginative correspondent was doomed to "speer" in vain. He will be glad to hear that the "Missus" is well, and not so very far from his north, but if she should call to see the gardens she might perhaps not "let on" again. A "Traveller," too, would almost feel constrained to make a quiet call if he knew the address, but he knows now, if he did not before, that editors are selfish mortals over addresses. They get all they can, but part with none in response to applications. The "touring" season is not yet, and "pawky chiel" must wait.]

— **THE BEGINNINGS OF PLANTS.**—In one of his recent lectures, Professor Ray Lankester showed that the primal difference between plants and animals was based upon what each was able to eat. The organisms which can only eat substances of no lower chemical elaborateness than starches, sugars, and albumens are said to be holozoic; and all animals belong to this class. Those which can eat oxygen and carbon and nitrogen, and have the power (with the help of chlorophyll and sunlight) of separating oxygen, are called holophytic. But between these two comes the anomalous class—the organisms which have a mouth and eat animal's food, and yet have chlorophyll corpuscles to enable them to get sustenance as the plants get it. These, we say, are saprophytic, and it is among such organisms that we have to search for the point where the animal world and the vegetable kingdom start. There is green plant called the *Englena* which has a mouth, and yet has the chlorophyll corpuscles which would class it as a plant; and there are among the tiny organisms of the "flagellata," or whip swimmers, several we should class as animals, and yet which have the green corpuscles in their minute structures. This is, therefore, one reason for believing that it was among the "flagellata" that the vegetable kingdom first found its origin. Broadly speaking, said the professor, one might say that if in the beginning a group of "flagellata" joined themselves end to end so as to form a thread, they turned into a plant; whereas if they followed more complex courses and joined together in more elaborate structures and households, they became animals.

— **HARDINESS OF CLEMATIS INDIVISA AND SWAINSONIA GALEGIFOLIA.**—Touching the Editor's footnote on page 178 of this Journal, I desire to say it was my intention to write "*Clematis montana*," and not *C. indivisa lobata*, which is a recognised greenhouse climber. A plant under the name of "*Swainsonia galegifolia*," is, however, growing and thriving at the foot of a west wall in Bedfordshire, and receives no protection whatever.—T. P.

— **CLIANTHUS PUNICEUS IN THE ISLE OF WIGHT.**—Mr. Charles Leslie Melville sends us flowering sprays of the New Zealand Glory Pea, gathered from a plant growing in the open air on the verandah of the cottage of Miss Hue, at St. Lawrence, about two miles from Ventnor. Accompanying them was a branch of *Ribes sanguineum*, laden with fully expanded flowers—the first we have seen during the present spring which have developed in the open air.

— **DAFFODIL PRIZES FOR SPRING, 1898.**—Since issuing the schedule of arrangements for 1898 the Royal Horticultural Society has received from Messrs. Barr & Sons of King Street, Covent Garden, the offer of a silver cup for Daffodils, to be competed for at the Society's meeting at the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, April 12th, open to all amateurs. Notice of entry should be addressed to the Secretary, R.H.S. Office, 117, Victoria Street, S.W., and must be posted on or before Thursday, April 7th. The particulars are:—Collection of cut Daffodils (*Polyanthus* section excluded), each of the three groups—*Magni-coronati*, *Medio-coronati*, and *Parvi-coronati*—being represented, the flowers to be arranged in bottles which will be provided by the R.H. Society. Not less than forty different varieties, and not more than three bottles of any one sort to be staged. Correct naming and elegance of arrangement will be taken into account.

— **STOCKS FOR APPLES.**—I note the remarks on page 205 on this subject, and gather from them that the general practice is to employ only the two quoted—the Paradise and the Crab. As I understand the matter there is a third—namely, the "free" stock, that is largely employed. This is obtained from the pips coming from the cider mills. It is distinct from, and is much more extensively used than the Crab stock. For general culture, especially where the soil is inclined to be heavy, and the trees have ample space in which to grow, my experience is that the free stock is far superior to the Paradise, as better growth is secured, and this means eventually a fuller crop of fruit. If the trees are correctly treated they will bear freely and early on the seedling Apple stock. Whether the trees will make fibrous roots instead of the reverse depends very much on cultural methods. If no encouragement is offered to keep the roots near to the surface it is not to be expected that fibrous roots will be found in quantity, and without these successful crops of fruit cannot be secured.—E. M.

— **EPHING FOREST.**—The Epping Forest Committee of the Corporation have just issued their report upon the work carried out in the forest during the past year. It is stated that a large area of the forest has been judiciously thinned in order to encourage the growth of young and promising trees—namely, Oaks, Beeches, and Hollies—and with a view also to making the beauties of the domain more accessible. The portions thus dealt with include Theydon Coppice, St. Thomas's Quarters, Honey Lane Quarters, Loughton Forest, Whitehouse Plain, Lord's Bushes, and Walthamstow Forest. The Committee also report that they have made an inspection of other portions of the forest where thinning is required, and instructions have been issued for the carrying out of the work. In order to hide from view brick walls and other enclosures, which do not improve the appearance of the forest in places, the planting of small clumps of trees has, says a contemporary, been carried on. Planting of a similar nature has been done on a portion of Wanstead Flats. At the desire of the inhabitants of the locality a portion of Bell Common has been planted with an avenue of trees in commemoration of her Majesty's Jubilee. The digging out of a large piece of swampy land, known as Holloer Pond, has been accomplished at a cost of £1228, to which the Leyton District Council contributed £300 and the Corporation £650. The result is a fine piece of water some 8 acres in extent. A suggestion by the Essex Field Club that the local museum in the forest should be enlarged has received due consideration from the Committee, who report that the cost of the work is estimated at £250. The proposal will be further considered. The sale of thinnings during the year amounted to £643 13s. 9d. The keepers' wages were £1150, and labourers' wages £1085. The Committee recommend that £4000 should be placed to the credit of the Committee to meet the expenses of the coming year.

— **TEA ROSE MADAME LAMBARDE.**—On the 12th inst. I gathered two beautiful flowers of this Rose, one of which I send to you. The plants are growing on the terrace walls near the Castle, and flowers are the result of buds formed late last autumn. The same plant made young shoots 6 inches long with flower buds also in January, but these are not yet expanded.—W. H. DIVERS. [The flower was a richly coloured one, but unfortunately dropped to pieces when taken from the box.]

— **MINT.**—I see on page 196 "*E. D. S.*" speaks of manuring Mint as being beneficial. This is contrary to my experience, and also that of several gardening friends. I find that manuring it causes a kind of fungus, which destroys the whole of the stock. My method of dealing with Mint beds is to top-dress with about 2 inches of good soil, and this has invariably proved successful. I should like to know if any readers have had a similar experience to mine.—H. S.

ROYAL HORTICULTURAL SOCIETY.

MARCH 8TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair); Rev. W. Wilks, Mr. A. Sutton, and Rev. Prof. Henslow, Hon. Sec.

Phytoptus ribis.—An interesting letter was received from Miss Ormerod giving an account of what is being done experimentally at the Duke of Bedford's fruit farm at Woburn, under the direction of Mr. Spencer Pickering, F.R.S. As to the possibility of obtaining "mite-proof" Black Currants, the only result has been some plants received from Budapest, which she has distributed to the Toddington fruit grounds, to Mr. Speir Newton's farm, Glasgow, and to Woburn. Miss Ormerod has given as exhaustive an account as she could form of the disease in a special appendix to her twenty-first annual report, from the period of its first appearance until the present time. A series of experiments are now being set on foot at Woburn directed to every point which is open for serviceable action, including chemical applications. These will be followed by expert examinations of the contents of the galled buds treated; and with coincident examination of galled buds under precisely similar circumstances, but not treated chemically. These experiments will be found detailed in the appendix, pp. 141-158. A conclusion anticipated is that there should be "a difference in broadscale method of growing."

Scotch Fir, Malformation.—Mr. Veitch sent a curious mass of stunted boughs, the whole resembling a hedgehog, and probably caused originally by a phytoptus or fungus. Dr. Masters observed that short boughs struck from such specimens were used as miniature trees, for rockwork, &c.

Sprouting Broccoli.—A remarkable specimen was received from Mr. W. P. Wright, Willesborough, Ashford, Kent, from the central and much enlarged stem of which a large number of good sized lateral shoots had appeared. It was suggested that if it be capable of being "fixed" it would probably prove a valuable acquisition.

Phytoptus on Hazel.—Mr. G. Gordon sent specimens of this well-known complaint, allied to the Currant mite. The samples were received from Kent, where the Black Currant is badly infested. It was first observed at the locality on the Hazel last year.

Orchid Roots with Fungus.—With reference to the specimen brought to the last meeting, Mr. Murray of The Gardens, Oakwood, Wylam-on-Tyne, writes to say that he is "convinced that it is from no other cause than from the want of air, or, rather, circulation of air, among the plants." In a previous communication to Mr. Douglas he expressed agreement with Mr. Veitch's interpretation, but not quite in the manner he explained, for he observes, "I ventilate the houses day and night with the ventilators, . . . but the air upon the stages, or, rather, above the stages, when the plants are standing close together, travels very slowly, even with ventilators open, in comparison with that around the centre staging, as plants thereon seldom show signs of fungus."

Two and Three-Spathed Arums.—Mrs. Richards of Westridge, near Ryde, forwarded two flowers, one with two spathes, the other with three, both from the same plant. They were very fine instances, and it was reasonable to expect such might prove constant. If so, a permanent form with two or more spathes would be very desirable.

Azaleo-dendron.—A hybrid between an *Azalea mollis* or *sinensis* and a *Rhododendron*, received from Sir Trevor Lawrence, was unanimously awarded a botanical certificate. It was raised by M. Le Prof. Pynaert of Ghent.

Large Ivy Stem.—Prof. Henslow exhibited a section of Ivy, some 10 by 8 inches across. It grew round a tall Holly, about 50 feet in height, at Zeals Rectory, Wilts.

Twin Apple.—A remarkable monstrosity was sent from Mr. Bar-at-Gin, 3, Praed Street. Instead of being the result of the fusion of two flowers, as occurs in Tomatoes, &c.—i.e., a "synanthic" condition, a vertical section revealed the fact that they were the result of a bifurcation of the axis below, the under side of the Apple giving no signs of its being a twin.

Cypress Diseased.—A specimen received from Dr. Church, having the bark split and detached and infested with fungi, was forwarded to Kew for further examination. The following report was received:—"Cupressus dolabrata.—This is a typical example of bark-scorching, the cortex being first killed by exposure to the sun's rays, afterwards splits and forms sun cracks, and finally separates from the wood. The fungus present—*Corticium lacteum*, *Fries*—is simply saprophytic on the dead parts."

FUCHSIAS AS ROOF PLANTS.

MANY years ago, when visiting the famous Chatsworth gardens, I was delighted with the appearance of some large Fuchsias trained to the rafters of one of the plant houses. The numerous shoots which were sent out in all directions were borne down by the weight of the flowers, which hung in charming undulations, regulated by the length of the various shoots. A pretty picture indeed it was, upon which the eyes of the many visitors present lingered with unfeigned pleasure. Since that time I have had many opportunities of growing Fuchsias in similar positions, and have invariably noted the admiration they commanded. The roof of a conservatory, greenhouse, or other cool structures afford ideal elevations upon which to train these popular plants, for in no other positions do their elegant flowers display so fully their graceful beauty.

Admitting, as I believe most readers will, the correctness of the above remarks, it is a trifle strange that, when considering what plants we shall employ for roof ornamentation, the good qualities of the pendulous Fuchsia should often be overlooked. Still it is "never too late to mend," and I trust this note will serve to remind many that they may, with advantage, begin to atone for their past neglect of an old favourite. Those who do so will doubtless have plenty of material at hand with which to make a good start, for Fuchsias, as pot plants, are abundant enough in the majority of gardens. A good vigorous example, in an 8-inch pot, is a capital type of plant to commence operations with, though, of course, failing such, younger ones can quickly be grown on for the purpose. I prefer to plant in borders where such are at disposal, or can be formed, but have often grown them in large pots or tubs for draping roofs or walls.

In many greenhouses borders from 18 inches to 2 feet in width, with a depth of about 18 inches, are already in existence, and such dimensions answer very well, though when they are either a little more or less they serve the purpose equally well, for in some instances I have grown very large plants in borders only a foot in width; it is then simply a matter of feeding highly and paying close attention to details. A few inches of drainage formed of clinkers, broken bricks, or potsherds, to be covered with rough turf, leaves or straw, should be placed in the bottom before the border is filled with soil.

A suitable compost is formed of the following ingredients—good turfy loam three parts, partially decayed manure one part, with a little charcoal, and a 7-inch potful of half-inch bones given to a barrowload of the other ingredients. If the loam is inclined to be heavy some sharp sand should also be added, and if the plants are to be set in pots or tubs, as much leaf soil as decayed manure may with advantage be also incorporated. The reason for making this little distinction is that in the case of a pot plant the leaf soil promotes rapid root action, but is exhausted by the end of the season, then repotting puts matters right again; but when growing in a border we want a given quantity of soil to give up food more slowly, and to remain sweet and fertile for a number of years.

March is a capital month during which to plant. Old plants which have broken freely should be selected, the soil shaken away from the roots, so that they may be spread out evenly in all directions, after dead and damaged points have been cut away. This spreading out of every rootlet, so that its whole surface comes in contact with the soil, has a wonderful effect in securing quick and strong growth. Too deep planting should of course be avoided, the safe rule being to cover the surface roots with about an inch of soil. If a compost similar to that described is used, it may be pressed moderately firm, but does not need a great amount of hard ramming; we then get strong shoots to start with, such as will quickly go to the top of a rafter, and when the allotted space has been covered it is quite easy to suppress undue vigour.

If pots or tubs are to be employed for growing the plants in I like to have them well established in fairly large pots before placing them in their final position. Those that were shaken out and potted in February, will in a few weeks be ready for another shift; then, when they have rooted freely into the new soil, they are ready for the final potting or tubbing. To induce the leaders to grow to the top of the house quickly I usually stop the side when they have made two or three joints, but when once the allotted space is covered no stopping is practised; the plants are simply allowed to grow away at will, but whenever the shoots become crowded some of the weaker ones are removed, and a gap is filled by tying a shoot across it.

A rafter densely clothed from base to summit with Fuchsia shoots, from which depend myriads of drooping flowers of various shades of colour, is a sight not soon forgotten. The growth, however, need not be confined to the rafters alone, for although it is often undesirable to densely shade the whole roof of a conservatory, a light shade is an advantage. If, then, wires are stretched between the rafters from 3 to 4 feet apart, and a shoot taken along each wire, we can manage to drape the roof in a beautiful garb without unduly shading the plants beneath. The pillars which support the roof may also be used to train Fuchsias upon, and indeed there is no reason

why we should not have a Fuchsia house, one in which both walls, roofs, and pillars are entirely draped with these popular flowers.

Anyone who is bold enough to carry out the idea will, I think, be rewarded by a feast of beauty, which will totally eclipse the display obtained in any house where a mixture of creepers have been planted. When autumn comes round, the plants should be kept dry at the roots, just as they are usually treated when grown for ordinary purposes, and at pruning time all side growths ought to be cut in to within one or two eyes of their base; in fact, they may be pruned upon exactly the same system as Vines. When the plants have covered their allotted space, the borders will be packed with roots, and during the growing season liberal treatment must be given in the shape of liquid manure or artificial fertilisers, watered in with abundance of clear water. If this practice is well followed up, and a top-dressing of fresh soil and manure given annually, the plants will give satisfactory results for a quarter of a century.

Strong young varieties should, of course, be selected for the purpose, and the following selection will be found to include many of the best:—

Doubles.—A. D. Neuville; Ballet Girl, white corolla (grand); Burzeward; Champion of the World, sepals coral red, corolla dark purple; Madame Jules Chrétien, and Phenomenal.

Singles.—Aurora Superba; Blushing Bride, white tube and sepals, scarlet-lake corolla; Charming; Dominiana; Madame Thibaut, tube and sepals bright rose, corolla rose margined with white; Olympia, Emperor, Rose of Castile, Lustre, Lord Beaconsfield, and Mrs. Marshall.—H. D.

For some years now one of the most charming summer features of the Chelsea nursery of Messrs. J. Veitch & Sons, Ltd., has been the long span-roofed house with its overhanging Fuchsias. Here, any season, may be seen an example of the system so ably advocated by our correspondent, and all who have noticed it are unanimous in praising its merits. The plants used at Chelsea are usually two years old, and needless to say, only the strong growing varieties are chosen. By the courtesy of Messrs. Veitch & Sons we are enabled to reproduce a photo which was taken when the Fuchsias were at their best, and it will be agreed that the picture is an effective. The varieties represented as in flower are Olympia, The Shah, General Grenfell, Miss Berrage, Mrs. Rundle, Mrs. Todman, and Phenomenal, the latter being the weakest grower, and only suitable for using in conjunction with one of the others. Visitors to Chelsea this summer should make a point of seeing this house, which is situated on the left-hand side of the central walk opposite the large Palm house.

FAIR DEVON.

(Continued from page 141.)

THE region of the "Tors" is one of the most interesting districts of inland Devon, for there we find striking contrasts between charming scenery and the sternly sublime or weird aspects of Nature. There is a peculiar fascination for the observant traveller in all the granitic outcrops of Great Britain, for it seems as we go back in geological time we enter upon a totally different world from that we are familiar with in the less rugged contours of more recent formation. The contemplation of the scenery characteristic of such regions has an invigorating effect upon a healthy mind, just as cold water braces the muscles of the body, while warm water relaxes them. A change of scene is beneficial to all, and gardeners, like others, may so assiduously devote themselves to their duties that their minds become too cramped or narrowed in their range of ideas. When business can be combined with the mental relief sought it is an advantage frequently from a pecuniary point of view, but there are times when such considerations must be placed upon one side and health becomes of the first importance.

Holidays pure and simple must be indulged in at times, though I confess to a natural disinclination for the merely idle rest, needful as it may be, and I have for many years been fortunately able to combine some work with the recreative and instructive change afforded by journeys throughout our islands. If, however, I had to choose a locality for a holiday apart from business, one that would certainly have prominent claims upon me is the region of the Tors, the vast expanse of Dartmoor Forest, which occupies so large an area of central Devonshire. There the pedestrian has ample space for his wanderings, and if he be a naturalist he can find abundance to engage his attention in the 200 square miles of wild moorland, over the greater part of which he is free to roam unchecked. This extraordinary expanse, which extends nearly north and south for about twenty-five miles, varying in breadth from ten to twelve miles or more at some points, is a vast outcrop of granite barely covered at the more exposed places with sufficient soil for grass, in others forming a peaty mass of a boggy nature. But wherever the rock has been sufficiently worn down a

moderate turf is found that provides excellent fodder for numbers of sheep that are annually turned out there, as well as for the sturdy Dartmoor ponies which may be seen scampering about in many parts.

The "forest" will be sought in vain unless the traveller journeys to Wistman's Wood in the neighbourhood of Two Bridges, where a few peculiar stunted Oaks appear to be the only vestige of the ancient forest that at one time covered a great portion of the "moor." Now it is singularly bare of any vegetation approaching the size of a tree, though the botanist who is interested in Ferns, Mosses, and other minute forms can find plenty to study. In all directions the most

fine day is chosen for the journey, and the traveller is favoured with fair weather until he reach his destination, the experience will be a most enjoyable one, for when the warm, moist valleys are left behind, and an elevation of 1000 feet or so is reached, the air becomes most invigorating, notwithstanding the frequent rains. Extensive and delightfully varied prospects are obtained on the way: the huge, frowning tors only serve as a foil to the brightness of the landscape, and the wildness of the moor is pleasingly picturesque. But such is not often the fortune of the visitor, especially in late autumn; and there is another side to the picture. In one of my journeys it was brilliantly sunny in Tavistock at starting, and this continued far up into Tor-land, when suddenly a strong cold wind brought up a dense mist,

Photo by

FIG. 52.—FUCHSIAS AT CHELSEA.

E. Braun, 435, Fulham Rd.

prominent objects are the towering bare peaks that assume grotesque or forbidding forms, and which are designated "tors," variously translated as meaning a "heap of stones" or a "tower." Rising high above the level of the moor they have a most weird effect when the observer is near them, and they are visible at great distances in the surrounding country when the atmosphere is clear. Some of the most notable peaks are Crockern Tor, Feather Tor, Cock's Tor, Sheep's Tor, Great Mis Tor, Vixen Tor, and Brentor, culminating in Yes Tor, which reaches an elevation of 2050 feet; but the list might be extended to far greater length, including dozens of other tors of varied proportion and heights.

If the visitor is approaching Dartmoor by road Tavistock is a good point to start from, as the ascent is comparatively easy, and the distance only about eight miles to Princetown, or, as the local residents tell one, it is "eight miles there and four miles back." If a

and the whole aspect was altered. We were literally amongst the clouds, and to see the masses of mist drifting across the moor, sometimes partly and at others wholly shrouding the tors, imparted a wildness and a dreariness that was most impressive; it only wanted a driving snowstorm to complete the picture. The wanderer on foot who has departed from the roads or known tracks has a sorry prospect if he be caught in such a fog alone and far from a resting place, for he may spend many a weary hour in seeking a refuge.

There is another means of reaching Princetown, and that is by train from Yelverton, a junction on the Great Western line from Tavistock to Plymouth. The Dartmoor railway is a remarkable and interesting piece of engineering, the line rising at a very steep gradient, something like one in sixty-five; and as the passenger commands some most extensive and beautiful views on the way, it is

a favourite route with numbers of visitors who do not care to face the journey by road.

Princetown is small, but it occupies a remarkable situation nearly in the centre of Dartmoor, and its elevation above sea level being something like 1400 feet, it enjoys the distinction of being one of the highest towns in Great Britain. Except for its convenience as a centre for visitors to Dartmoor, it is not a very enticing place, for it is inseparable from the great prison for convicts, which darkens the town with some of the worst shadows of human life. But there is a bright side even to this, for it is astonishing to see the piles of substantial and even stately structures which have been erected by convict labour. With all the cold rigid sternness characterising such a place, there is still the evidence that the men are being taught to do useful work, which may in some cases possibly enable them to become of service in the land when they are released from the hand of the law. In one department particularly, which was the special object of my visit—the farm—land cultivation is carried out on a scale that could be attempted in few places where labour is scarce and expensive. Something like 2000 acres have been reclaimed from the wild district round the prison, and a large part of this has been brought under spade cultivation, with astonishing results in crops and returns. It is an uncommon sight to witness 200 men digging with spades on one piece of ground, yet this is what I saw; and the thought arose in my mind what a wage's bill I should have to meet at the end of a week if I had such an army to pay at the current local rates of 1s. 6d. per square pole. Still it is a great object lesson, for certainly few soils could be so unpromising as that on Dartmoor, yet with abundant labour and the free use of all the refuse from the prison a marvellous transformation has been effected; certainly the desert has been made to smile. No more healthful occupation could be found for the men, and the whole farm, including the dairy and stock departments, are highly creditable to the officials.

Readers may observe there is not much "gardening" in these notes, but the Editor says that a change is good occasionally even in the contents of our much valued Journal; but to compensate for the horticultural shortcomings of this letter the next shall be all gardening to conclude.—VIATOR.

(To be concluded.)

ARTIFICIAL AND FARMYARD MANURES.

THE concurrence of opinion resulting from experience concerning manures is too well established to be set aside by the assumption that their action is empirical, and that it can in any way be simply a matter of faith, or that they have no useful place in the economics of the cultivation of the soil. Such simple faith would apply, as a matter of fact, quite as much to farmyard manure as to artificials, in so far as actual plant food is provided, which even stable manure does not give unaided, as we are again reminded on page 193, in the following words, by Mr. W. Dyke:—"The organic nitrogen in farmyard manure is during decay converted into ammonia. The ammonia is then changed by certain nitrifying organisms into nitric acid. The acid when formed in the soil unites with lime and forms nitrate of lime, and it is from this source that plants obtain their chief supply of nitrogen." The very pertinent question arises, "Is lime present to effect the valuable conversion, without which even stable dung would be mainly only a mechanical agent instead of a plant food?"

Referring now to experiences (such as on page 186), they do not appear to be founded on a complete set of scientific experiments, but rather on a series of rule-of-thumb methods. The presence of a dark horse is also apparent on page 200 in a few lines on "Artificial Manures," where it is stated, "The same kinds of artificial manures do not produce the same effects in differing soils. Those who use them can only relate their experience." Exactly so! The article proceeds, "If one person find them of service he has good reason to speak in their favour; if another use them carefully with no practical results, he can only say what is true. His land and crops did not need them." Precisely so! The labour and expense were wasted. The dark horse ever returns.

The simultaneous appearance of the articles referred to in your Journal furnishes the opportunity for drawing attention to the omission of an important factor, so far as any positive references are concerned. There is substantial merit in the articles cited and referred to by me, and the subject deserves all the solicitude it can engross at the hands of the writers, but only so far as they go. The dark horse is unheeded; an important link is missing in the operations alluded to. As a step in the right direction I find much written about the importance justifiably attached to guarantees of the strength of fertilisers: but it is a strangely incomplete proceeding when exact science is aimed at, that the predominant partner in the whole affair, the chemical constituents of the soil, seem to remain unobserved, or, to be more exact, unmentioned. Are they treated as a negligible quantity all round? and is the result of elaborate mixtures on chemical lines thus usually a matter of chance as to outcome in part, if not an entire loss occasionally, except always where lengthy direct experiments have taught the lesson to a man growing old over its accomplishment?

The reduced charges for analysis of the soil render the expense in proportion a trivial one. It may be useful to direct attention, as stated on page 20 and page 26 of the R.H.S. Journal (Arrangements for 1898), that at the reduced charge of 10s. a partial analysis of the soil will be made by Dr. Voelcker for Fellows of the R.H.S., including determination of clay, sand, organic matter, and carbonate of lime. The charge for a complete analysis, including plant foods, is £3.

It is the proportion of lime to be ascertained so cheaply to which I wish to direct attention, as this useful material is lost sight of in the absence of an analysis of the soil. Yet science tells us that lime turns dormant plant foods into available ones, and destroys the bad qualities of substances that prejudice growth, and acts as an antidote to sour soil. It also decomposes organic matter into plant food, and has a physical influence besides. It even improves light soils by rendering them less porous. Its application thus becomes a general corrective, where proved deficient by analysis of the soil, naturally or through absorption by crops; and I feel convinced that in many cases of the use of sundry manures lime would accomplish the main part necessary much more cheaply, and would save heavy amounts of indiscriminate outlay on manures. The simple analysis of every variety of soil on any estate would save absolutely from groping in the dark, a condition of things that appears common.

It is interesting to read in this connection also the following, from a report in the "Standard" of Professor Warington's lecture before the Newcastle Farmers' Club, on the subject of compensation for the use of foods and manures:—"Mr. Warington shows that operations which constitute improvements on some soils are really deteriorating on others, and that the residue of fertility left by manures varies greatly with the character of the soil."

This statement leaves also the gist of what I have at heart, that the soil should be analysed before manuring. Owners should be guided in the selection of manures by the result of analysis of the soil.

When all is known that can be by systematic analysis of the soil, and the manures are determined in accordance therewith for the respective crops, direct experiments should be made to complete the evidence by proof supplied by various crops as would be propitiated in accordance with knowledge that science supplies so abundantly. It would seem a small matter for large cultivators of leading crops to dedicate every year some corner of any fields of sufficient extent, and of homogeneous soil, to experiment on one or more different crops, technically known as deriving assistance from existing conditions, and thus have proof supplied as to which crops, in regular rotation or otherwise, would deserve preferential treatment on any particular plot of land.

Nor are far reaching effects of a correct interpretation of all the phenomena alluded to absent, for a crop growing with fair vigour, from attention generally bestowed, will possibly escape insects, pests, and other drawbacks from which a weakly crop would certainly suffer soonest, such crops which would, for instance, grow on land that has deteriorated on Professor Warington's principles.

Although the subject of this article is suggested by correspondence in a horticultural journal, the wider range of its application to the cultivation of the soil on large agricultural estates is equally manifest, and is alluded to in various ways. It is only in reference to the actual analysis of the soil that I wish to suggest possible opportunities nearer home in the various centres of education created under the management of County Councils or agricultural and horticultural societies, which might be preferred for convenience to the address given by me.

I should not wonder if in gradually increasing attention to the niceties of these problems may be discovered an unsuspected source for improvement, unsuspected by the many, for the cultivation of the soil and its results, with a gradual suppression of importations.—H. H. R., *Forest Hill*.

[This article was one of others in type for our last issue, but unavoidably crowded out.]

TRITOMA SAUNDERSI.

I AM fully persuaded Tritomas are not nearly so much grown as their merits deserve. When seen in groups or large masses they make a wonderful and effective display, and coming into flower at a time when most other things are on the wane, makes them doubly welcome.

Last autumn, on the 9th of October, I saw a plant of *T. Saundersi* in the garden of W. T. Hindmarsh, Esq., Alnbank, near Alnwick, which I am not likely soon to forget. Mr. Hindmarsh is an excellent gardener, and, from the position this plant occupied, evidently understands the requirements of Tritomas. It was growing in the middle of a large and beautiful bed of tuberous-rooted Begonias. The centre of the bed is considerably elevated above the ground level, which not only gives a greater amount of heat in the growing season, but keeps the plant drier at the roots during winter. The plant was 4½ feet high, and nearly 3 feet in diameter, and carried thirty-four splendid spikes, a few of which were at their best, and measured 1 foot in length, of a uniform shape, and of a bright and cheerful colour.

No Tritoma I have seen produces such a charming appearance, and all who do not possess this variety should make a note of it. There is an idea that Tritomas are rather tender. Mr. Hindmarsh thinks that, like some other plants, they suffer more from damp during winter than from frost, and I believe this is quite true, hence the necessity of planting them in a rather elevated position. We have lifted all our Tritomas, and replanted them on a higher level.—N. N.

NATIONAL CHRYSANTHEMUM SOCIETY—IMPORTANT NOTICE.

THE adjourned annual general meeting of members will take place at Anderton's Hotel, Fleet Street, E.C., on Monday, March 21st next, at six o'clock in the evening, to receive the Committee's revised statement of accounts, together with an estimate of receipts and expenses for the current year; to elect a President, Vice-Presidents, officers, and Committee for the year ensuing; to consider certain amendments to the rules, and to transact such business as pertains to the annual general meeting. The attendance of members is particularly requested.—RICHARD DEAN, *General Secretary*.

THE KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY.

WE are officially informed that a meeting of the Committee was held on Monday evening, and the position of the Society was gone into thoroughly. The whole of the liabilities have been discharged, with the exception of what is due to the collector and Assistant Secretary (Mr. W. D. Elsam), who voluntarily offered to let that stand over. It was satisfactory to find that last year's subscriptions exceeded in amount the sum received in 1896, and had the takings at the door come up to the average, with a small reduction *pro rata* from the prize money (which is provided for in the rules and is often done at other shows), the accounts would have stood differently. As it is, the Committee is determined to make an effort to wipe off the debt due to the collector, and is encouraged therein by the knowledge that the Society has passed through critical periods more than once in its existence of twenty-one years. It has now been definitely fixed to hold the Show on November 1st and 2nd, and Major Ficklin has again kindly allowed the use of the Drill Hall for the purpose.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE usual monthly meeting was held on Wednesday, the 9th inst., when there was a good attendance of members present. Dr. Banham was elected Chairman. The routine business being completed, a discussion on Chrysanthemums was opened by Mr. W. Willgoose, a successful amateur grower, who strongly advocated the late rooting of cuttings in order to get the plants dwarf, and instanced cases when by adopting this system he had produced as good blooms as he had formerly grown by a longer period of cultivation. April and May he considered suitable months in which to start with cuttings for this district. A number of both professional and amateur members entered warmly into the discussion, but the result of the remarks showed that the opinion of the speakers varied considerably on the subject. The varieties grown, the time in which the plants were wanted, the quality and quantity of the blooms required, being all important factors that required taking into consideration before deciding upon which system should be adopted, were prominently brought out in the course of the remarks, which, however, proved to be one of the best and most popular discussions held at any of the Society's meetings. The exhibits for professional members were pot plants, when Mr. C. Scott obtained first prize for an excellent *Dendrobium nobile*, and Mr. W. Topham the second prize for a very fine *Azalea indica*. The amateur members competed with cut blooms, when some good varieties of Orchids, Azaleas, Callas, and Rhododendrons were staged. Mr. M. H. Willford secured first honours, Mr. P. Cox second prize, and Dr. Banham the third prize. After the admission of new members a hearty vote of thanks to the Chairman, Dr. Banham, and to Mr. Willgoose for opening the discussion was passed.

EARLY FLOWERING CHRYSANTHEMUMS.

THESE charming and useful plants are now obtaining a greater share of public attention than they did ten years ago. At one time I had my doubts if they would ever get their heads above water, their big brothers securing all the attention. Now, however, even those growers who go in for the large blooms give considerable attention to these more modest, but often more useful flowers. For single-handed gardeners, lady gardeners, and amateurs, especially those who dwell in town suburbs, the early flowering Chrysanthemum is a most useful and economical plant. The blooms are beautiful when cut for use in the house, lasting such a long time, while if the varieties are well chosen they make a splendid display in the garden, and that without any great skill or trouble.

I have in my charge one of the largest and most complete collections in the country, and last season was cutting flowers of many varieties in July, and, owing to the very mild season, right into November. Of course, many people may say that Chrysanthemums are not wanted in July or August, when there are plenty of Dahlias and other flowers to be had; but the enormous quantity of border Chrysanthemums now grown proves that many people are not particular what flower they have, provided it is good to look at and not difficult to produce.

The culture is very simple, while, like everything else, they pay for good attention. My system with young plants is to root the cuttings in February, and then either put them into 2½-inch pots or run them out with a spade into a cold frame until the end of April, when they are planted out 2 feet apart on a border of good rich soil. I do not stop the plants, but let them break naturally. They can be pinched, and thus

make bushy plants, but they are a little later in flowering. When high enough we stake with bamboos or other stakes, and tie securely, paying attention to this during the season, especially with the taller varieties. It is best to let them flower without disbudding, when they will produce delightful sprays for cutting, the blooms being just the right size for table and house decoration.

Where it is possible to obtain the space, a reserve bed should be planted (the bed to be about 4 or 5 feet wide) with the most suitable varieties for cut flowers. Up each side of these beds stout stakes can be driven in, and spare lights laid across in the autumn, thus protecting the flowers from excessive wet and early frosts. Plants can also be readily lifted and placed on a bed in a cold house, or potted in 8 or 9-inch pots. This is a good way with the later flowering sorts, such as Ryecroft Glory, Souvenir de M. Menier, Mons. G. Menier, Roi des Precoces, Mons. A. Dufour, and Jeanne Vuillermet.

The following are the best of their class so far as I have yet proved them. I give twenty-four Japanese and twenty-four Pompon varieties, but those who have not room for all can take the first twelve of each, and they will have a splendid collection.

JAPANESE.—Lady Fitzwygram, white, 2 feet, September; Mytchet, white, August, 2 feet (this is the best introduction since Mons. G. Grunerwald); Mrs. J. R. Pitcher, August, 4 feet, a lovely pale pink; Madame Carmeaux, 1½ foot, August, soft pink, changing to white, a splendid variety, and will be universally grown in a short time; Mons. G. Grunerwald, 1½ foot, August, pink; Madame Marie Masse, 2 feet, August onwards, reddish pink, most persistent bloomer; Edith Syrratt, 2 feet, August, light pink; Orange Child, September, 2½ feet, large yellow flowers; De La Guille, September, 3 feet, deep orange, passing to yellow; Baronne C. de Brailles, 2½ feet, August, white flushed with pink; Crimson Queen, September, 2 feet; Mrs. Burrell, August, 3 feet, primrose; Mrs. Hawkins, August, 3 feet, yellow; Mons. Dupuis, August, 2 feet, orange yellow; Madame Eulalie Morel, 2½ feet, September, cerise, with gold centre; Vicomtesse d'Avene, 2 feet, August, deep rose; Mdle. Guindudeau, 2 feet, September, deep pink; Madame Armand Groz, September, 2½ feet, primrose yellow, salmon centre; General Hawkes, 4 feet, September, crimson amaranth, a very striking variety; The Don, lilac, 2 feet, July, very profuse; Madame Foucher de Cariel, 2 feet, September, bright orange; Coral Queen, 3 feet, September, a distinct variety of amber colour; Harvest Home, 2 feet, September, red with gold tips; and Albert Chausson, 2½ feet, September, orange red, tipped yellow, a fine variety, and most profuse flowering.

POMPONS.—Although these are not quite so graceful when cut as the Japanese, they are very satisfactory in the garden, being persistent in flowering, resembling huge bouquets of colour, and flower very early. Piercy's Seedling, 1½ foot, August, orange yellow; Strathmeath, 1½ foot, August, rosy pink; Toreador, 2 feet, July, crimson, golden reverse; Longfellow, 2 feet, July, ivory white; J. B. Duvoir, August, 2 feet, pale pink; L'Ami Conderchet, 1½ foot, July, primrose; Madame Jolivat, 2 feet, August, blush white; Nanum, 1½ foot, August, white; Flora, 2 feet, July, the best yellow; Blushing Bride, 2½ feet, August, rosy lilac; Bronze Bride, 2½ feet, August, a splendid sport from the above; Mrs. Cullingford, 3 feet, August, the best white; Golden Fleece, 2 feet, August, a lovely yellow; Canari, July, 2 feet, a fine yellow; Alice Butcher, 2½ feet, August, red, shaded orange; Mr. Selby, 1½ foot, August, a lovely pale pink; Martinmas, 3 feet, August, light pink; Early Blush, 2 feet, August; Fred Pele, 2 feet, July, crimson, tipped gold; White St. Crouts, 2 feet, August, very hardy and free; Silversmith, 2 feet, August, lovely white; St. Mary, 2½ feet, August, white; Precocite, 3 feet, August, yellow; and La Vierge, 1½ foot, August, pure white.

The time of flowering and heights given are average, they of course vary a little according to the situation, whether grown in the north or south of the country.—S. J.

EXHIBITING HARDY HERBACEOUS FLOWERS.

I VENTURE to make a few remarks, and hope they will be the means of bringing out the opinions of other growers on the above subject. From what I have seen and heard at exhibitions, it seems to me the majority of exhibitors are of opinion that some sort of restriction with regard to the size of the bunches ought to be adopted.

During the last few years the size of bunches has increased correspondingly to the larger quantities of herbaceous plants now grown. Generally the prizes go to the "big battalions," although many of the stands contain much of what may be termed inferior quality. Were the bunches limited to a certain size, I feel sure that the quality would be improved, as scarce and newer varieties would be oftener exhibited. It would also increase competition, as many smaller growers would then be able to compete. Most ladies and gentlemen are pleased for their gardeners to exhibit and win prizes, but one can easily understand how they would object to such large quantities of flowers being cut for such a purpose.

Where classes are provided for nurserymen by themselves it is not so material about the size of the bunches, as many of them grow hardy herbaceous plants to a large extent, and can cut almost any amount; besides, there can be no better advertisement than making a great display. I would recommend that where spikes are exhibited no more than eight or nine should be allowed in one tube, and in the case of single flowers on one stem not more than twelve or fifteen.—N. N.

[In the R.H.S. Judging Code the maximum size of tube is indicated for holding the flowers, with the proviso that all the stems must reach the water.]

AS OF A DREAM.

(Continued from page 99.)

I FEAR, for 999 persons out of 1000, it would be uninteresting and difficult to conceive of were I to unfold the anxiety hinging upon the mind of the owner of two small Potatoes planted in a Seakale pot, the which by work and watchings for initiative development had cost so much time: therefore, I will leap over the minutiae and intervening cultural details to land myself in Westminster, in November, 1895, with the produce of one tuber of them only that had been induced to fulfil its destiny, and to gain the approval and a "united vote of thanks" from the R.H.S. Fruit Committee. Soon after the above event I received letters from Mr. J. Horsford and Mr. C. G. Pringle, Charlotteville, Vermont, U.S.A., from which short extracts may not be without interest.

Mr. Horsford wrote:—"I was interested to learn of your perseverance in crossing the *Solanum Fendleri* on the common Potato, or with it, and I trust you may live to see good results from this work. Potatoes have not had as much interest for me because there were so many new varieties on the market that the chances for profitable work in that line seemed much smaller than in some other lines. But with different species, who can tell what time may do? Mr. Burbank's success with fruits has given some very remarkable new things. If we may believe half what the catalogues say, he has done a service to the world. Mr. Pringle is not dead, but one of the liveliest men in America."

Mr. Pringle soon afterwards wrote:—"Twenty years have brought many changes, but I am still alive, and you can see that I have been active, when I tell you that I have been a botanical traveller since 1881, and have crossed the Continent every year to make journeys of many months' duration on our Pacific coast and in Old Mexico. I have worked eleven years in Mexico, till I have collected probably one-half its plants. Kew, the British Museum, and other institutions in various lands, possess thousands of my specimens. You may infer, and truly, that I have almost forgotten horticulture—but not old friends. Your mention of *Solanum Fendleri* reminded me that I have for your trial seeds of a rare tuberous species, and I enclose them herewith. The leaf is like a Pear leaf (it exactly represents a Sage leaf) not divided. There is rare pleasure for me in living under the bright skies of the Mexican table-lands, and working amidst the rich flora there."

I have copied the above extracts for your acceptance. Not only do I wish to have the origin of the hybrids placed beyond question, but very much more, to show the good feeling of my correspondents, which I hope may continue to predominate with America for all the English speaking Race—with a capital, Mr. Editor?

I will now return to my exhibits at the Drill Hall, in November, 1895. I planted the 100, the result of the second cross, in the spring following. They threw a strong, upright haulm, unique in blossom, leaves, and florets intermixed, upon long stalks. I tried to impregnate innumerable pistils with pollen from my early and late varieties, but with no results. In themselves they are sterile. One of the stools threw a late coronal of flowers, and I had proved in cases like this it might be my chance to find some lagging behind blossom to give me pollen.

I generally plant some of my International Kidney about midsummer, to produce us young Potatoes late in the autumn. They throw late blossoms in abundance, hence my opportunity, though I had to wait some days for farina, but the moment the pollen was ripe I applied it to the pistils of the hybrids' flowers, and to my infinite satisfaction it caused berries to swell and ripen, and produce me seed. The hybrid's crop turned out to be a late variety, and the tubers resulting took a grand leap, much resembling the Rector of Woodstock, though not sufficient in crop or flavour for commerce; but they were and are much appreciated by the missus for Irish stews on account of the manipulated sections holding to their entirety—viz., "not boiling to squash." Buchanan's antiblight powder kept the haulms intact, as in fact it did, and has done for the last five years all my Potatoes, and Tomatoes included, to the end of their chapter.

Now for the year of grace 1897. I sowed the precious seed in the tray in the glass house, and looked sharp after the woodlice depredators this time you may feel sure. Thirty seeds germinated, and became in their due time planted singly in flower pots. They were kept growing there purposely till "Jubilee Day." I mentioned it in a paper you printed concerning a hall for horticulture, how I, as a churchwarden, was calculating upon reseating our St. Michael's Church, in commemoration. It was done. I placed a last wedge under a seat, to make it level, on the eventful morning, and then "home," as old Pepys would say, to plant out the young hybrid Potatoes. We completed this operation just about the time that her Majesty was returning her thanks at the foot of the steps of St. Paul's; and the missus, Alice, myself, and David (my man) were making the welkin resound to the words of our anthem—God Save the Queen! Well, you have heard of it before that we are loyal people at Cottage Farm, so we will let that pass.

We were left severely alone all the season; no one but Mr. Arthur Sutton, his nephew (the youngest member, just admitted into the firm), and Mr. Lasham (head of the Potato department) favoured me with a visit—in fact, "sent to Coventry" may be the term for me and my experimental work last year. I must let you know about some of them in a future paper, as this is running to an unconscionable length, but I want to have it out with you about the hybrids, as far as they will carry me, as I seem to fear I may not have another year's cultural opportunity with them.

I narrowly watched the features of each plant through its growth; about a dozen showed precociousness and promise of tuber; others must

be crossed again to correct a wild tendency and induce the plants to bear their tubers "nearer home," and again in the after years probably more crossings, and certainly many more trials for growth and crop, and then the crucial finales for cookings and quality. All may possibly be achieved say by A.D. 1910. But it could be done, I give you word for it. How it will fare with the last comer from Mr. Pringle I cannot as yet guarantee. I have tried to cross it with my true English breed for two years, but it refuses. I pin my faith, however, to the mystic number three.—ROBERT FENN, *Sulhamstead*.

SOME FLORISTS I HAVE KNOWN.

ON the 12th inst. the Rev. F. D. Horner was the lecturer to a large gathering of members of the Bradford Paxton Society. The lecturer stated that, like crystals round a piece of string, his reminiscences of his many dear old friends were crystallised round him in happy memories, which necessitated the treatment of his subject, "Reminiscences of Some Florists I Have Known" from an autobiographical standpoint. He had no wish to push his own personality into prominence more than was necessary; but as his dear father, who was a physician in Hull, was the first florist he knew, his memories were carried back to his earliest days, and he had no conception of any time when his own love for flowers was dormant.

His earliest attempts at floriculture were made in his nursery windows during a protracted illness, when he utilised his empty medicine bottles as receptacles for the growth of the common field Bean and Pea, and for the propagation by cuttings of *Nasturtiums* and similar old-fashioned garden plants. These experiments in gardening, and the lessons they taught him, left a deep and abiding influence on his character. In those days the sectional florists' shows followed each other in regular succession. The Polyanthus, Auricula, Tulip, Ranunculus, Pink, Carnation, and Picotee each in its turn gave interest and pleasure to cultivators, and before he was high enough in stature to look down on the stages his father used to take him by the hand and initiate him into the standard properties of the blooms. Then came his college days, and after that his probation curacy in a slum district of Liverpool. Of course, this meant well-nigh impossibilities to gratify his passion for flowers; but on his appointment to the curacy of Normanton, then a country village, he then began to form his collection of Tulips.

During the early seventies he was appointed to Kirkby Malzeard, near Ripon, and at that period began his more general acquaintance with his contemporary florists. Strange to say at Normanton, so near Wakefield, he was so engrossed with his duties, and his spare time being devoted to the cultivation of his then favourite flower, that no opportunities had presented themselves to form an acquaintance with the Wakefield florists. He was glad, however, to state that this was remedied afterwards, but it left many regrets for the congenial fellowship which he had then missed. The lecturer then stated that his acquaintance with the late Mr. Barlow of Stake Hill, Manchester, originated in a remarkable incident. At the time Mr. Barlow was thinking of leaving England, and offered his valuable collection of Tulips for sale, and amongst them was a bulb of Annie McGregor, so perfect and constant in its feathering that Mr. Horner never remembered one to equal it, and his father purchased it at the price of 20 guineas, at which price Mr. Barlow would only part with it on conditions that he had the option of reclaiming it at any time at the price given. The reasons for Mr. Barlow's expatriation were removed, and for a time he forebore to press his claim to repurchase, and in the meantime the bulb was destroyed by an unfortunate accident, leaving Mr. Horner in the unfortunate position of being unable to fulfil his part of the bargain. Although they both highly valued this extraordinary bulb, Mr. Horner with much feeling said that as the loss of it was the cementing of a life-long friendship between them, he had often blessed the accident. Anecdotes in connection with the names of Messrs. Barlow, J. Bentley, sen., J. Bentley, jun., Ald. Wooler, Sockport, Slater, Cheetam, Mills, W. Whitaker, J. Jackson, Woodhead, J. Simonite and Ben Simonite, and others were given.

Although he had confined his reminiscences to florists north of the Trent, he could not let the opportunity pass without expressing the obligation due from all florists to the late Dr. Hogg, who, in addition to his genial personality and claims of being an ardent florist, was at all times ready to place space for reports of shows and other matters at their disposal in the columns of the *Journal of Horticulture*. The lecturer concluded his interesting remarks with an eloquent and generous tribute of esteem to his florist contemporaries, whose sense of fair play in competition was only equalled by their steadfastness to the florists' "ideal," and their perseverance to attain it.

After a cordial vote of thanks had been passed to Mr. Horner, the Chairman, Mr. Scott, drew attention to a superb specimen of *Dendrobium nobile* exhibited by Mr. Moreby, gardener to Mrs. Knowles, Moorhead, Shipley, and he proposed that the Society's certificate of merit be awarded to Mr. Moreby in recognition of his success with that grand old Orchid. That plant with twenty flowering bulbs carrying twenty flowers each was but the fifth in size in the Moorhead collection, the largest plant in it had seventy-five breaks, carrying considerably over 1000 flowers.—T. G. W.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE annual general meeting of this Society took place, as announced, at the Caledonian Hotel, Adelphi, Strand, at 8 P.M., on Monday, the 14th inst., Mr. George Wythes of Syon House Gardens, Brentford, in the chair. After the minutes of the last annual general meeting were read and passed, the Chairman called upon Mr. Collins to read the report and balance-sheet for the year 1897. The statement of assets and liabilities was read by Mr. J. Hudson, who said that the balance to the credit of each member was duly invested. He also stated that in the assets the £13,100 represented a present value of no less than £14,742 10s.

Mr. Wythes, in moving the adoption of the report and balance-sheet, said that it had given him great pleasure to listen to the most satisfactory accounts of the working, financial and otherwise, of the Society for the year ending January 10th last. From inquiries he had made previous to the meeting he was enabled to glean something of the progress of this excellent Society, not only during the past year, but for some years prior of that. Compared with the earlier years of the Society, the progress made was astonishing. The Society had at the present time an invested capital of £13,000, which was really worth £14,742 10s. As there were 720 paying benefit members, this would work out at nearly £20 10s. per member. He paid a compliment to the admirable manner in which the affairs of the Society were managed, for the entire working expenses during the past year were only 6 per cent. of the income. Mr. Wythes thought, however, the reason why such a Society did not increase in membership strength more rapidly was because there was too much negligence and apathy on the part of intending subscribers. Proceeding to give other figures, he said that the annual investments for the last two years were £1200, and that £10,000 in all had been invested during the last thirteen years. The members should not lose sight of the fact that the executive Committee is still enabled to allow each one respectively 3 per cent. per annum on the balances standing to their account in the ledger. This allowance of 3 per cent. cannot go on many more years at the present price of sound trustees' stocks, which realise now only between $2\frac{1}{2}$ and $2\frac{3}{4}$ per cent. At one time these stocks could be purchased below par, and this no doubt was the reason why 3 per cent. has been continued so long. The more carefully he read over the rules and regulations of the Society the more he felt disposed to give credit to the originators of "The United." Every member should do his best to obtain fresh members, never missing a chance to press home the essential features of the rules, to bear in mind the motto of the Society—"Union is Strength." The speaker had not the slightest doubt that there are many candidates for the pension of the Gardeners' Royal Benevolent Institution who would be only too glad if they were members of the United, many of whom do not appear to have belonged to any society at all. He advised all young gardeners especially to join without delay.

W. Marshall, Esq., seconded. He said that as one of the originators he was glad to congratulate the Society on its success. It was started with eight or ten members, and now they had 720. He had always found gardeners to be civil, obliging, and deserving men, and was glad to do what he could for their benefit. On being put to the meeting, the report and balance-sheet were unanimously adopted. On a motion by Mr. Cole, it was decided to print and circulate 2500 copies of the report and balance-sheet.

At the election of officers which followed Messrs. W. P. Thompson, E. T. Cook, Wheeler, and Wood were unanimously re-elected as members of Committee. Mr. Cole proposed a hearty vote of thanks to the Treasurer (Mr. J. Hudson) for his excellent services, which was received with acclamation. Mr. Hudson suitably responded, assuring them that he was glad to do all he could. When he first took the post of Treasurer he invested £200 the first year; last year he invested £1200. On the proposition of the Chairman, seconded by Mr. J. Hudson, Mr. W. Collins was unanimously asked to continue the office of Secretary. Both proposer and seconder spoke very highly of Mr. Collins' services. That gentleman briefly replied, and acknowledged the pleasure he felt in performing the secretarial duties, aided as he was by such a capital Committee.

On the motion of Mr. J. Hudson, Mr. Collins received for 1897 a salary of £20 according to rules, a bonus of £5, and 6d. from each member over the number of 300.

Votes of thanks to the Committee, the Trustees, to the Press, and the Chairman were passed.

THE SPECIAL GENERAL MEETING.

A special general meeting followed upon the conclusion of the "annual," for the purpose of considering the advisability of altering certain rules.

Mr. Hudson proposed that Rule VIII., referring to the Secretary's salary, read "£30" instead of £20.

Mr. Burge moved, and Mr. Cole seconded, that in Rule XIV., after the words "lower scale," the words "with the privilege of increasing this to," should be added.

Mr. Thompson proposed, and Mr. Winter seconded, that the word "successive" be struck out of Rule XIV. Mr. Thompson showed conclusively how important this was in the case of a member going on the funds after having been on a few weeks previously, say for twenty-four weeks, when by declaring off for a week or two he would again be eligible for the full series of twenty-six weeks at full pay.

All these alterations were carried, the last-named after some discussion.

On the motion of Mr. Cole, a new rule relating to the Voluntary Convalescent Fund, was added, to be called Rule XVIII. It read as follows:—"The object of the Fund is to give members a change of air during convalescence. The Committee of Management to have power to relieve members of this Society from the Voluntary Fund as they may deem advisable. All cases must be recommended by a duly qualified medical practitioner."

RED SPIDER IN VINERIES.

I HAVE been reading Mr. Thomson's articles on the above subject with much interest, for whoever propounds a safe and certain remedy for the destruction of red spider on Vines will be one of the greatest benefactors gardeners ever had. I have usually resorted to sponging Vine leaves with an insecticide for routing their enemy, as I dislike the parching atmosphere created by painting the pipes with sulphur, the results as to the "spider" being with us of a very fleeting character. It may have been the fault of the sulphur, but it was what is generally known as flowers of sulphur. However, I desire to be on the right track, but am somewhat confused as to the exact product Mr. Thomson advocates.

By reference to the "National Encyclopædia," I find that although sulphur exists in Iceland, Teneriffe, St. Vincent, and some other places, the expense of obtaining it is so great, that Sicily is almost the only source of supply. Anyhow, that upwards of nine-tenths of the whole quantity imported into this country is received from Sicily, where the native sulphur is roughly purified. The sulphur thus obtained is imported into this country and again refined by distilling in a large iron pot; the vapour is condensed in a spacious brick chamber in a fine pulverulent form, known as flowers of sulphur.

Further, the article states that sublimed sulphur or flowers of sulphur is a slightly gritty powder, without taste, and without odour till heated. Precipitated sulphur or milk of sulphur resembles sublimed sulphur in its general properties, but is much paler in colour, and is in a finer state of division. Also that sulphur is obtained on a large scale by decomposing with an acid the crude calcium sulphide obtained from the vat waste from the alkali manufacture, but only part of the sulphur can be thus extracted. Is this where the difference occurs, or is it in the different method from that usually practised that proves its efficacy?

I should esteem it a favour if Mr. Thomson would put me right in the matter. I stand indebted to him for much that I have learnt through the teaching of his various works and writings, probably to me of double interest, knowing, as I do, the spot of his earliest achievements, of which in past days I heard much; also those of his old friend, the late Mr. Thrower, of High Canons, to whom he refers in the last issue of the Journal, which gardens I have visited in the long ago, and seen the good man and his work. I trust your able correspondent may long enjoy his well-earned rest, and still assist us with teachings from his long and successful experience. — J. J. CRAVEN, *Allerton Priory Gardens, near Liverpool.*

CENTAUREA CANDIDISSIMA.

I HAVE had at various times large quantities of this plant to propagate, and my favourite method of proceeding is similar to that of your correspondent on page 176. I used to slip off one or two side shoots from each plant about the first week in August, and without much trimming place one in each pot of sandy loam. Water was then given to settle the soil firmly around the cutting, and the pots were then plunged in leaf mould in a cold frame behind a north wall. About 90 per cent. or rather more would form roots, and if the frame were on a dry bottom, and the lights in good order, they were wintered in that position. I invariably found damp to be more injurious than a few degrees of frost.

Anyone wanting large numbers of this handsome foliage plant will do well to adopt the plan suggested. The advantage of taking the cuttings so early is that they have time to root, and become well established before the winter. One or two pieces from each of the old plants are not missed, and will not interfere in the least with the decorative effect of the flower garden or bed. Although these plants are easily raised from seeds, I prefer autumn-rooted stock, and besides, I find indoor space early in the year is too valuable for such plants as can be successfully wintered in cold frames.

I can fully endorse all your correspondent says of the combination of this plant with *Coleus Verschaffelti*. I once saw a magnificent bed not more than six miles from Deal, and within sight of the Downs, which has left a lasting impression on my mind; and whenever speaking of *C. Verschaffelti* this particular bed flashes before me. I very much regret the latter will not succeed outdoors here. — J. EASTER, *Nostell Priory Gardens.*

I HAVE read with interest the remarks which have appeared in recent issues of the *Journal of Horticulture* as to the best methods of propagating this handsome plant. We grow it largely, and find no difficulty in keeping up the number required for bedding purposes, for which it is admirably adapted, and is one of the most effective plants we have.

Cuttings may be had in abundance by placing the old plants either in the reserve garden or the herbaceous border, and by twisting out the crown as soon as it commences growth the small shoots at the side will in a very short time grow apace and be fit for insertion in pots (well drained) of sandy soil. I prefer pulling the cuttings downwards from the parent

plant and inserting with a heel; in fact, similarly to propagating Carnations. The cuttings should be covered with a bell-glass, which must have the moisture wiped from it twice daily. A half-spent hotbed is found to answer the best for rooting the cuttings.

Seedlings are easily raised, and we find them come true to character. A few old plants were selected last year and planted in an open and sunny position, where they flowered and seeded freely. The seed was gathered as soon as ripe and sown at once, and we now have a number of healthy plants. Although they have not grown very large, we shall find them invaluable for edgings to smaller beds for the summer months. Then by the autumn at lifting time they will make excellent plants.

We raise a number of seedlings annually for potting. The plants may be utilised in the greenhouse or conservatory with excellent effect during the dull winter months. This *Centaurea* is very impatient of excessive watering, therefore we allow the plants to become almost dust dry before applying water in the winter season.—H. T. M., *Stoneleigh*.

CHOICE ANNUALS FOR CUTTING.

NEVER, perhaps, in the history of the floral world has there been such an increasing and popular demand for cut flowers as at the present day, for there is no function however small in which floral decorations do not form an important part. It is essential, therefore, in making our selection for the ensuing season to choose annuals not only for their bedding qualities, but for their peculiar gracefulness and beauty and their enduring properties as cut flowers.

There are undoubtedly frequent failures through hurrying seeds into cold soils before the season is advanced enough for them to germinate and grow freely; it is therefore necessary, in order to get plants as far advanced as possible, to sow under glass in a moderate heat. Shallow, well drained boxes filled with light, rich sifted soil are suitable for this purpose, the compost consisting of equal parts of loam, leaf mould, peat, and sand. Sow thinly, cover the seeds but slightly, and place in a temperature of about 55°. Should the soil be in a proper condition for the reception of the seed very little watering will be required till the seedlings appear, when shading from the midday sun and a slight watering occasionally will be all that is necessary. As the seedlings progress give more light and air, and when large enough prick them out in light, rich soil in cold frames, giving air during the day and slight protection at night. By this means strong plants may be expected for transplanting into their flowering quarters in May.

Of course, in all lists of any pretensions, Asters and Stocks hold a foremost place, but those who have not yet tried the beautiful single Aster *Callistephus sinensis*, would do well to include it in their lists this year. It is a beautiful Marguerite-like flower, having a most charming effect in loosely-bound bouquets and other cut flower work, while its varied colours, its lightness and gracefulness, make it exceptionally valuable. Stocks are splendid bedders, and a good strain of Ten-week yields every shade of colour with a good percentage of double flowers; but among these the pure white variety, "Princess Alice," should hold a prominent place. This is a large and bold sweetly scented variety, and most useful for cutting. *Cosmos hybridus* is not so generally grown as its merits deserve, as it is a most charming annual of very easy culture. The flower very much resembles the single Dahlia, being, however, smaller and more graceful, while its elegant *Nigella*-like foliage greatly enhances its value and beauty. The seeds, which are rather large, germinate quickly, and as the plant grows to about 3 feet in height, it forms a valuable addition to the flower border, blooming continuously until cut down by the autumn frosts.

Sweet Sultan, or *Centaurea suaveolens*, should become more extensively grown. It is delicately scented, and for cut flowers is becoming a great favourite in the market. White, yellow, and purple are the colours usually grown. The *Salpiglossis* is among the most beautiful of all annuals, its varied and brilliant colours, so delicately veined, making it exceedingly attractive. A group of this superb annual is a sight to be remembered. *Phlox Drummondii grandiflora* has been wonderfully improved during the last few years. It is a most profuse bloomer, and if the seedlings are pinched back they make well branched plants by bedding out time, and flower continuously until the autumn. Verbenas are easily grown as annuals, and the many new hybrids added recently have greatly increased their value. By growing yearly from seed, the mildew which frequently attacks old plants when grown through the winter for cuttings is avoided. The Marguerite Carnation, if sown early, will bloom profusely in the autumn, either in pots or in the open ground. *Calliopsis grandiflora* is a brilliant golden flower which will soon become popular. Sow the seeds in spring and prick out as soon as the seedlings are strong enough. This is a continuous bloomer, and a gem for cutting.

The New Star and Little Gem *Antirrhinums* with their fine blooms are admirably adapted either for pots or bedding purposes if sown in spring on gentle heat and planted out in June.

Many other annuals might be enumerated as worthy of culture for the purpose of supplying cut blooms, among them being Chrysanthemums, Scabious, Sweet Peas (Eckford's new varieties being worthy of a place in any garden), and Mignonette; but it is unnecessary to refer to them in this paper, as I have endeavoured to bring to the notice of your readers only those which seem to me not so generally known as their peculiar merits deserve; and all gardeners, where cut flowers for decorative work form an important feature, would do well to add those enumerated, and in doing so I can assure them, as one in practice, they will not regret their endeavours.—W. R. GOTT.

THE SCIENCE AND PRACTICE OF FORMING FRUIT TREES.

(Continued from page 207.)

LAST week reference was made to different methods and times of shortening the branches of young bush or standard trees, planted either during the last autumn or the present spring. The illustration on page 207 represents the practice of not cutting back all the branches at the time of planting, or when the buds are dormant, but waiting till the buds towards the extremities of the branches are bursting into growth, then shortening the long and strong branches, leaving for a time the short and weak shoots to develop early leafage for the purpose of influencing root formation. The practice is also shown in the present illustration (fig. 53, E), while another, and more commonly adopted method, of shortening the whole of the branches when dormant, is represented in F. A few remarks pertaining to both may be elucidatory.

PYRAMIDS.—All trees may be suitable for bushes, but not all for pyramids, some naturally forming these with little trouble, and the pruner, who acts in accordance with natural principles, effects the greatest good at the least expense. The tree (E) shows this character, having a central shoot or leader (o), and four lateral growths or side

FIG. 53.—PRUNING RECENTLY PLANTED FRUIT TREES.

References.—E, shortening the strong, and leaving the weak shoots intact; o, leader; p, strong side shoots; q, short and weak shoots. F, shortening all the shoots, r, to the cross marks; s, to basal buds. G, uncallused root for fibre production; H, jagged and dying back root.

shoots (p) little less vigorous, with some shorter and weaker (q). Pruned, as indicated by the lines across the shoots, strong growths will issue and the pyramidal habit be retained without much need of manipulation; the tree becomes well established on leaving the weaker parts intact till the new growths above q are extending freely.

2, THE CUT-ALL-SHOOTS-BACK SYSTEM.—F represents the principle. This course certainly results in plenty of growths when the root system is good, the tree having been transplanted in the autumn, but when the roots are meagre little can result but weakly growths both above ground and within it. The late planted tree will neither have callused at the roots nor have the buds nearly so forward as the early planted, especially if lifted whilst dormant and moved from market to market. This is an exceptional case, and I am not disposed to question the close pruning system in such case. The root (G) shows fairly what has to be done for the production of fibres as shown in D (page 207), before there can be free growth, which cannot be expected from an injured root (H), as it will die back more or less through decay at the point of damage.

Quite apart from these considerations, and the tree being a fac-simile of the one figured last week, and planted at the same time, the question is whether we get as good growth by pruning it at the time of planting or before the growths have started, as in the early spring. That the pruning would be best deferred until the terminal buds had commenced to grow accords with the safety from frost principle, and in effect favours the view that the roots will be in advance of the top when the pruning is done to practically dormant buds. On the other hand, when the law of reciprocity comes into force, as it does undeviatingly, top and root

growth are alike influenced by stored matter, and the activity of this is promoted by warmth and moisture.

The tree (r) shown in fig. 53 is intended to indicate what is meant by hard pruning, and leaving nothing but essential parts. The shoots (r) are cut back a few buds nearer the base than in the other tree, and all the weak growths (s) shortened to a bud at their base, even the spur (t) is cut back. It is the pruning for shape system, and I am not by any means certain as to whether it is not the best for trees that have not been recently moved, and must suffer a large reduction of roots in transplantation, especially when on free stocks. That is another phase of the subject, for the stronger the tree the more roots it loses, and the greater need for the curtailment of the branches. In order, therefore, to arrive at any clear deduction the systems must be carried out on similar trees under an identity of conditions, so that the results cannot possibly be questioned. For those reasons three trees have been selected as near as may be alike for illustrating the points in respect of pruning before mentioned, and there remains but one more, namely—

3, NOT SHORTENING THE SHOOTS IN THE SEASON OF PLANTING.—In this case, leaving A (page 207) and F in the present sketch, just as they are at root and top, there are a few considerations that must have attention. If the tree has a large top and few and short roots, it will probably swell the buds and even produce a little growth; yet there it ends, and the probability is that it will die or linger on, not making any top growth of consequence until headed hard back another season, or, under the most favouring circumstances, take two years to recover. On the other hand, a young tree with shorter growths and a good system of roots, as often seen on dwarfing stocks, the balance is not so greatly disturbed, and there is the less necessity for close shortening. For the purpose of illustration, neither strong nor weak examples are chosen, but good average typical trees, such as are raised by experienced nurserymen for supplying to their customers. We, therefore, start fair with all the trees, and thence proceed to results, which will be shown in future issues.—G. ABBEY.

(To be continued.)

LONDON'S OPEN SPACES.

IV.—BATTERSEA PARK AND KENNINGTON PARK.

ONE important metropolitan improvement always to be remembered to the credit of the poor Metropolitan Board of Works was the conversion of the dreary wilderness of Battersea Fields into a lovely park. Formerly the resort of the riff-raff of the town, it is now quite a fashionable centre, while its once aristocratic neighbour, Ranelagh Gardens, has faded into bricks and mortar. The picture of Battersea Fields forty years ago is anything but inviting. A flat and unbroken waste of some 300 acres, 'it was a sort of 'no man's land,' on which ruffianism claimed to riot uncontrolled by any other authority than its own will.' The Sunday scenes were a scandal even in none too fastidious times, and the pugilistic encounters, dog fights, and other barbarous exhibitions were abolished by magisterial order in 1852.

Many duels were fought in the fields, the most famous of these being the encounter between the Duke of Wellington and the young Earl of Winchelsea only eight years before the Queen came to the throne. The Duke was Premier at the time, and with his characteristic impetuosity thus chose to resent an attack on him for his support of the Roman Catholic emancipation schemes. A letter in the "Standard" newspaper (then but two years old) spoke of Wellington's "invidious designs for the infringement of our liberties and the introduction of popery into every department of the State." The laboured phrases of the youthful Earl's letter seem to sober-minded people of to-day small provocation for an "affair of honour." The ducal Hotspur, however, insisted on the encounter, and on March 21st, 1829, the two noblemen faced each other on Battersea Fields. The Duke won the toss, giving him the right of firing first, and, fortunately, missed his man. Then the Earl discharged his pistol in the air, and offered a tardy retraction and apology. On the edge of Battersea Fields stood the Red House Tavern, familiar to every reader of "Sketches by Boz." It was equally famous for its pigeon shooting and for acting as the winning-post of many a lusty boat race. Tradition has it that Cæsar crossed the Thames 50 yards west of this spot in pursuit of the flying Britons, the reason being that there existed here till very recently a natural ford in a shoal of gravel not 3 feet deep, and broad enough for ten men to walk abreast.

Happily, at the time the great outcry was raised against Battersea Fields the demand for lungs for the swiftly growing metropolis was arousing public interest. The Red House, with its shooting grounds, was purchased in addition, making a total acreage of 185. The Metropolitan Board of Works in a few years converted the wilderness into gardens of surpassing beauty. For the land a sum of £246,500 was paid, and altogether £65,500 was spent on the laying out and improvements. Now it is so rich in trees, shrubs, and flowers that many claim Battersea Park to be no insignificant rival to Kew Gardens. Its Palm trees alone would make it famous. In the acclimatisation garden are wondrous Aloes, giant Cacti, and gorgeous growths of the tropics in strange neighbourliness to flora of the Alps. The lake of Battersea, too, is a vastly popular pilgrimage. It winds round beautifully wooded islets and under rustic bridges, its waters bearing many rare and curious species of water fowl. The great avenue of the park is the modern rival to Rotten Row, but beauty no longer mounts her horse but rides in bloomers on a bicycle. On some days the votaries of the wheel may be counted in hundreds, and all

lady riders have made their earlier runs on its smooth roadway. Battersea also has cricketer records, one of the most enthusiastic wielders of the willow here being John Burns. The local member is, it will not surprise many people to learn, a "desperate slogger."

Kennington Park, which stretches for some distance along the old Roman road, near the Oval, was known as Kennington Common until a comparatively few years ago. It was then an unlovely waste, practically grassless, and decorated with nothing better than broken kettles, dead cats, and other domestic flotsam. Round it ran some tumble-down wooden rails, which were not sufficient to keep donkeys from straying there. Field preachers and political orators also made it one of the chief scenes of their performances. It consisted of about 20 acres. Suddenly it was seized with a fit of respectability, and, thanks to an annual vote of £1800 by the Government, clothed itself around with elegant iron railings, its area being at the same time cut up by gravel walks and flower beds and shrubberies. It also engaged a beadle to look after it. And so it became a park, and a considerable ornament to the neighbourhood.

In "A Tour Round London" in 1774, the author describes it as "a small spot of ground on the road to Camberwell, and about a mile and a half from London. Upon this spot is erected the gallows for the county of Surrey, but few have suffered here of late years. Such of the Scotch rebels as were tried by the Special Commission in 1746 and ordered for execution suffered at this place, amongst whom were those who commanded the regiment raised at Manchester for the service of the 'Pretender.'" Among those here executed were Sir John Wedderburn, John Hamilton, Andrew Wood, Alex. Leith, Towneley, and Fletcher, and Captain James ("Jemmy") Dawson, over whose body, as soon as the headsman's axe had done its terrible work, a young lady, who was attached to him tenderly, threw herself in a swoon and died literally of a broken heart. The event forms the subject of one of Shenstone's ballads. "Jerry" Abershaw, the notorious highwayman, was hanged here, his body being afterwards hung in chains on Wimbledon Common. St. Mark's Church now stands on the place of execution. On April 10th, 1848, the great Chartist demonstration took place on Kennington Common. About 50,000 assembled, under the leadership of Feargus O'Connor and Ernest Jones. Timid people hid their spoons in waterbutts, and talked of the Kennington revolution; but the fizzle of the movement is matter of history.

During the last century Kennington Common was, at holiday times, an epitome of "Bartlemy Fair," with booths, tents, caravans, and scaffolds, surmounted by flags. It had also one peculiarity, for, as we learn from "Merrie England in the Olden Time," it was a favourite place for merry andrews and other buffooneries in open rivalry and competition with field preachers and ranters. It was here that Mr. Mawworm encountered the brickbats of his congregation, and had his "pious tail" illuminated with the squibs and crackers of the unregenerate. George Whitefield preached there frequently in 1739, often to 50,000 people at one time, while audiences of 30,000 were quite common. On June 24th, the same year, Chas Wesley preached there, in spite of the fact that he was under a prohibition not to preach anywhere until he had been before the Archbishop of Canterbury and accounted for his "irregularities."—"Lloyd's News)."

THE YOUNG GARDENERS' DOMAIN.

AN "OLD BOY'S" RECRUIT.

I HAVE read with great interest the contribution by "An Old Boy" on page 226, and trust his remarks will be the means of waking up young men who are able and desirous of making use of the "Domain" columns in the *Journal of Horticulture*. An opportunity like this has not been previously afforded, and we ought to make the page the success it ought to be as the work of young gardeners.

I have not hitherto contributed to the "Domain," having left the space to be filled by others, but lately there has been a marked falling off, and I hope that the article contributed by "An Old Boy" will be the means of stirring us up to fill its column to overflowing. Probably some young men have, like myself, sought fresh fields and pastures new in their upward flight in gardening. In such case I wish for them every success in their new surroundings.

Changing situations is essential to all probationers. Some of us look forward to a departure, not unmixed with regret, at leaving scenes and faces which have become familiar. Our chiefs often look upon a change as a necessary evil to be borne periodically, and very raw recruits sometimes have to be initiated into the mysteries of their respective positions. This I know to be one of the troubles common to head gardeners, and yet they would not seek to deter any of their staff from making a beneficial change.

I trust we shall again hear from "An Old Boy" in the near future; his contributions are always interesting and acceptable; his advice is such as might safely be followed by all bothyites, myself amongst the number, and I tender my thanks for the kindly interest he has shown towards us.—F. L. T., *Burwood*.

SEQUEL TO "AN OLD BOY'S" HOMILY.

SURELY everyone loves pleasant pictures—for their beauty, for their story, for both. Some picture scenes seem like finger posts guiding us to ideal lives, as our models. Here before me is portrayed in group—a patriarchal sage instilling wisdom to a cluster of eager young folk who nestle around him. In his right hand he holds an hour glass, his knees support an open book, and one almost sees the long grey locks quivering, and the shaky upraised left hand clinch for emphasis to his expositions.

There it hangs, a lasting reproof to indolence, having a latent power which never fails to inspire one with renewed resolves. Only last week we had a practical representation of a similar scene, when a good old man sought to encourage his young friends by a gentle homily. Shall we accept and act on such sound advice, and thus save ourselves from further reproof? Can we explain why "only half a dozen bright pens sustain the 'Young Gardeners' Domain?'"

Many seem to cling to the advice which Burns gave to a young friend:—

"Conceal yersel' as weel's ye can
Frae critical dissection."

Which advice they seem to have appropriated and acted well up to. Others forget that "youth comes but once in a lifetime," or that "a bad ending follows a bad beginning." We have another more gratifying response, though, to the question, in the fact that "a few (do) spend their evening hours"—aye, right up to and past midnight—"in studies and educational work." It is well when youths put a value on time, and prepare for a definite future, for worthy positions, and a glorious independence. "He is a wise man who, like the millwright, makes use of every gust." The "golden moment set with its sixty diamond seconds" is too much for poor folk to lose.

To write articles during the winter season is, happily or unhappily, more than some of us have time to allow for. Our aim then should be to obtain a sound foundation on which to build. This is only attained by prolonged studious application, necessitating the subversion of many things—writing among them. Industry is sweet. But why, when we do write, does the "Old Boy" expect only a few to enter by the teacher's door to this "Domain?" This seems unseemly. The whole of our literature is surely educational. However, everyone has not equal opportunities for gaining instruction in the sciences underlying our work; therefore the favoured minority in this respect might act more truly, as teachers to handicapped brothers.

It would seem, after all, that young gardeners are considered an immature fraternity, capable of little beyond writing a few lines on subjects beaten to death. Much garden print bears out this conclusion. We console ourselves by remembering that Pitman's phonography was invented by the late Sir Isaac at twenty-four. Burns died young, so did Byron. Loudon issued a work on forestry and landscape gardening when only twenty-four, and William Pitt controlled the affairs of a British Parliament while younger even than this. But —! "An Old Boy" has shown it to be our duty to build up a temple of knowledge. Then let us not be slothful. Keep such names as Lincoln, Garfield, Cleveland, and others of the "Log cabin to the White House" series of heroes ever in view, not forgetting David Livingstone, Kitto, Hugh Miller, Chalmers, and Cobbett as samples of hundreds more who have plodded onward and upward. These lines are often quoted:—

"The heights by great men reached and kept
Were not attained by sudden flight;
But they, while their companions slept,
Were toiling upward in the night."

These ruminations must now conclude. If it be that any of our present fellow workers become eminent, let us hope they may never rest contented by comparing their knowledge with those who grope below, but rather with those who soar far above them.—A YOUNG SCOT.

FRUIT FORCING.

Cucumbers.—Plants which have been in bearing all the winter in houses will require frequent attention. Remove all exhausted growths and bad leaves, encourage a free growth, stopping the bearing parts two joints beyond the fruit, and secure the growths to the trellis. It will much invigorate the plants if a little of the surface soil be removed, and a top-dressing of turfy loam, with a suitable chemical manure mixed in, be supplied; and when the roots are active in the top-dressing sprinkle a few sweetened horse droppings on the bed occasionally, feeding as required with liquid manure in a tepid state. Young plants will need more soil, adding to the hillocks as the roots protrude. Maintain a night temperature of 65° to 70° when mild, 70° to 75° by day from fire heat, keeping through the day at 80° to 90°, closing early in the afternoon, with abundance of moisture, securing a steady bottom heat of 80°.

Fermenting material-heated pits and frames which have been set to work some time will need linings about 2 feet wide. Look carefully to the frame after the heat generates in the lining to see that there is no accumulation of rank steam, preventing it by a little ventilation, especially when the sun shines. Add a little more soil as the roots spread on the surface, taking care to have it warmed. Attend to training and pegging the shoots, not overcrowding them; stop the leaders a foot from the side of the frame, and pinch the laterals one or two joints beyond the fruit. In watering do not wet the foliage more than can be helped. A night covering will be necessary to maintain a temperature of 65° to 70°,

allowing the temperature to rise to 85° or 90°, closing before it falls below 85°.

Melons.—The very early plants have made a sturdy growth, and are showing fruit on the first laterals. To insure these setting it is necessary to keep the bottom heat steady at 80° to 85°, with sufficient moisture in the soil to prevent flagging. A rather warm and dry atmosphere favours the production of pollen, affording a little air to prevent the deposition of moisture on the flowers. Fertilise the blossoms every day when fully expanded, and stop the growths one joint beyond the fruits. When these commence swelling remove all flowers, earthing up the roots by placing warm soil against the sides of the ridges or hillocks, pressing it firmly. Apply water as required, and sprinkle the floor in the morning and evening, lightly syringing at closing time when the days are bright.

To swell well, Melons require a night temperature of 65°, or a little more in mild weather; 70° to 75° by day artificially, 80° to 90° from sun heat, closing early in the afternoon so as to raise to 90° or 95°, even 100° doing no harm provided the atmosphere is moist. If a succession of fruit is wanted in the same house, some of the plants should be deprived of the flowers that appear on the first laterals; stopping these at the second joint will cause the sub-laterals to show fruit, which will be several days later. Place supports to the fruits in due course to relieve the plants of the weight. Make additional plantings, pressing the soil around each plant, shading for a few days if the sun be powerful.

Peaches and Nectarines.—*Early House.*—Trees started at the new year will require disbudding carefully, removing the strongest and ill-placed shoots, and have all the leading growths tied down, taking care not to overcrowd them. Proceed by degrees in thinning the shoots, taking off those on the under side of the trellis or otherwise badly placed. Syringe the trees during fine days, and ventilate early in favourable weather. The temperature may range from 55° to 65° at night, and 60° to 65° by day, ventilating at the latter temperature, and closing the house when the heat is decreasing, allowing an advance to 70° or 75° from sun heat. Avoid cold draughts of air, but admit a little air constantly and freely in favourable weather, so as to secure sturdy growths, well-developed foliage, and thoroughly solidified wood.

Houses Started in February.—The trees being now in flower, or nearly, should be examined, and if there are more flower buds than are needed, all those on the under side of the shoots should be removed, as well as others as necessary. Maintain the night temperature at 50° to 55°, and 55° by day, with a little ventilation, as a close atmosphere is fatal to a good set. Ventilate freely above 55°, but avoid cold draughts, and allow an advance to 65° with sun heat. Fertilise the flowers in the early part of fine days, either by shaking the trellis or drawing a camel's-hair brush over the flowers when the pollen is ripe. Syringing the trees must cease whilst they are in flower, but the floor should be sprinkled in the morning and afternoon of fine days.

Houses to Afford Ripe Fruit in Late July and August.—These being planted with midseason varieties, will afford fruit at the time named. Close the houses, syringe the trees two or three times a day until the buds show colour, when it must cease. Do not keep the trees constantly dripping with moisture, but damp sufficiently early to allow them to become fairly dry before night, and on dull days only damp the paths. The inside borders must be brought into a thoroughly moist state. Maintain a temperature of 50° by day, 40° to 45° at night, advancing to 65° with sun and full ventilation.

Late Houses.—If the lights are off there need not be any hurry in replacing them before the middle of March, as that will be early enough to have the trees in full blossom by the middle of April, and then they have the benefit of the sun heat. Many late houses are unheated, which is a great mistake, as the flowers, even in April, are not safe from severe spring frosts, and the fruit does not ripen well if the late summer be cold and sunless. A gentle heat during the flowering period does much towards a good set, and in autumn artificial heat ripens the fruit and wood, plumping the buds wonderfully. Houses with fixed roof-lights should be ventilated freely, and the borders must not be allowed to become dry, giving thorough waterings to insure the moistening of the soil.

Wall Cases.—Where these are employed, whether over Peach or other description of fruit trees, the chief consideration is retarding the blossoming. Peach and Nectarine trees, also Plums and Cherries, need not have the lights put on until the middle of March; but Apricots should have the lights put on when their flower buds begin to show white, and after they are placed on, ventilate freely, as nothing is so fatal to hardy fruit blossom as a close moist atmosphere. Those that have not had the roof lights removed may need supplies of water, so as to bring the soil into a thoroughly moist state, and may have the border mulched with a couple of inches thickness of rather short, somewhat fresh manure. Ventilate freely to retard the flowering to as late a period as possible.

THE KITCHEN GARDEN.

Globe Artichokes.—The protective material around Globe Artichokes ought to be removed before it has the effect of weakening fresh sucker growths. If top growth is far advanced when the winter covering is removed, afford temporary protection. It is yet full early to thin out growths or to form fresh plantations, but some nearly decayed manure might, with advantage, be given all that are well established. Bare the surface roots to a distance of 18 inches or 2 feet from the centre of each clump, give a dressing of manure, and cover this with the soil thrown back.

Celery.—For the main crop sow seed at once of pink and red varieties in preference to white sorts, as the former are usually the most solid, crisp, and nutty in flavour. Sow somewhat thinly on the surface of

boxes or pans of sandy soil, previously well moistened, press the seeds in it, and cover lightly with fine soil. Place in gentle heat. Shade heavily till the seed has germinated. If not already done, prick out the earliest raised plants in boxes of rich soil, placing them in gentle heat till well established, transferring them to shallow frames before they become drawn. Where Celery is wanted extra fine for the August shows it pays well to transfer the requisite number of plants from boxes in which they were first pricked into 5-inch or 6-inch pots, from which they may be transplanted with the least possible check in May.

Early Beet.—If there is a possibility of the supply of old roots failing earlier than desirable, early roots can be had by sowing the Turnip-rooted varieties thinly in boxes of light soil, placing in heat to germinate, hardening the plants when about 3 inches high, prior to planting them on a warm border or at the foot of a warm wall. Seeds may also be sown on a warm border thinly in drills 12 inches apart.

Lettuce.—Cold weather has checked the hitherto rapid growth of Lettuce plants that were set out in the open ground last autumn, but with a change to mild weather the more advanced may be loosely tied up to hasten blanching. More from the seed beds or frames should be planted on rich ground, and early winter-raised plants ought to be now nearly large enough for planting out. Seeds of some rapid-growing variety might be sown in boxes under glass. The plants resulting could be established on rich warm borders or open plots of ground, would heart well ahead of any raised quite in the open. At the same time sow seeds in the open, in drills 9 inches to 12 inches apart. Slugs are numerous, and must be prevented by frequent light surfacings of soot and lime.

Peas.—Those raised under glass for planting out ought not to be kept long enough in pots or boxes for their roots to become badly matted together and their tops stunted. Take extra pains with the preparation of the sites for them, plant somewhat thickly, because they will not branch strongly; firmly surround the roots with good fine soil, stake at the same time, and protect from cold winds. Peas sown in the open ground have come up strongly. Draw the soil up to them, more especially on the cold side, to protect the plants somewhat from cold winds, and stake early. The choicer second early or successional wrinkled seeded varieties may now be safely sown in moderately rich, deeply cultivated soil.

Potatoes.—With the ground in good working order planting ought to be persevered with. For these important crops cultivate deeply, the cleanest and best crops turning out of ground finely divided to a good depth. Late disease-resisting varieties should be given abundance of room, the rows being not less than 30 inches apart and the sets 12 inches apart in the rows. Shorter topped, quicker maturing varieties may be 6 inches nearer together. Keep a close look out for the advancing haulms of early varieties on warm borders, keeping it well moulded up, and otherwise protecting from frost when necessary.

Turnips.—An east border is the best position for early Turnips. In any case provide a well manured site, this promoting quick growth. The Extra Early Milan is the best for early sowing, with Early Snowball as a succession. Make the ground fine and firm; sow the seed thinly in drills from 12 inches to 15 inches apart, the first named variety requiring the least room. Dust the plants directly they are seen with soot and lime to save them from slugs and flea.

THE BEE-KEEPER.

DOUBLING HIVES.

ON page 179 "G. H." says "he knew the method and practised doubling years ago when in his teens." That, however, proves nothing. It may not be too late even now to suggest that if he again tried the system on slightly different lines he would find out that there is a right way and a wrong way of carrying out this operation, simple as it may appear. But if he be well satisfied with his frames of various sizes he will be well advised to keep to them. In doing so, however, he must not ignore what others are doing whilst managing their bees in a different manner.

"G. H." says "the arithmetic propounded is not a fair comparison," and goes on to explain that "by using two supers holding ten frames, each 20 inches by 5½," a much greater comb surface is obtained than in the super mentioned in previous notes as having nine standard frames. It may therefore come as a surprise to "G. H." to be informed that we have frequently had two supers of nine standard frames each, and a crate of shallow frames on a strong colony during the height of the honey flow, and, what is more satisfactory, they have been all filled. Now as regards the number of superficial inches of comb for storage purposes, he will find that his large hives and supers are "not in it." We have several hives of similar dimensions, and larger than those advocated by "G. H.," holding from twelve to twenty and upwards standard frames in the body of the hive, and our experience is that when shallow frames are used as supers it is a great advantage to reduce the number of frames in the brood nest, and place an extra crate of shallow frames on the top. If it is an extra strong colony, and honey is coming in freely, at least four crates of shallow frames may be used with success, and if "G. H." will give this plan a trial during the coming season we have no doubt of the result.

THE QUEEN'S LAYING POWERS.

"Has a queen room for her egg-laying power in the height of the season when she is capable of laying from 3000 to 4000 eggs per day?" This query refers to a hive holding ten standard frames, and we at once reply yes and no. This may appear somewhat of a paradox, but it is nevertheless true. As regards the number of eggs laid by the queen the weather must be taken into consideration, and the month of May is the time when bee-keepers are anxious to have as many young bees and brood as possible, as these are the bees that will be most suitable for gathering a surplus from the White Clover and other sources. But what is the condition of the weather during May? Taking one season with the other, cold sunless days have been the rule rather than the exception of late years, and instead of a queen laying the above number of eggs probably an average of 500 per day has been nearer the mark. This is no imagination; we have proved it many times, and contend that a hive holding ten standard frames affords ample space for the queen's laying powers at that season. Should the weather be exceptionally fine, and the brood nest is found to be crowded with bees, four or five of the frames of brood are removed into the super and their places filled with frames of fully drawn-out combs or foundation, as advocated in previous notes, and it will not be necessary to introduce any more bees from another colony.

When a hive is in this condition and does not receive attention at the right time, the stock will prepare for swarming. This proves the hive is not large enough, and fully illustrates what we have often endeavoured to show—that it is of little consequence what is the size of the frames or the shape of the hive if the bees have proper attention when they require it.

USING OLD COMBS.

Are old combs detrimental for storing a surplus? and is the flavour of honey affected thereby when they are used in the supers for storing a surplus? Personally we look on clean tough old combs as our sheet anchor. "G. H." says, "To my palate honey has the richest aroma that is taken from virgin combs, or from combs that have not contained brood." In theory this may be the case, but in practice it is not so. Bees will not store honey in the comb until the latter is in the right condition for receiving it. We very much doubt if "G. H." could detect the difference either in the flavour or appearance of honey obtained from clean combs that had previously contained brood, and virgin combs that may have been placed direct in the super.

We have often heard the same remark passed by bee-keepers and others who imagined they could easily detect the honey obtained from combs which once contained brood, but when given a practical test they found how difficult it was, and were more often wrong than right. The bees are too industrious and hardworking to store honey in anything but clean combs. They may be dark in colour, but the honey stored in them will be of spotless purity; and as a proof the aroma is good, and the colour and density all that could be desired, honey obtained from combs as above has gained high honours in strong competition.—AN ENGLISH BEE-KEEPER.

HOW TO MAKE A LARGE HIVE.

ON page 136 "Warwick" asks for information about making the large hive mentioned in a previous issue. I take it, from the first question asked by "Warwick," that the hives are for a bee house. That being the case it will be a very easy matter to make them. First procure some well seasoned $\frac{5}{8}$ deal. Make the side pieces first, which are 19½ inches long by 10½ inch deep; next make the end pieces, which are 18½ inches long by 8½ inches deep. Nail these four pieces together, and you have a hive 18½ inches square, inside measure. It will be noticed, now, that the back and front of the hive is $\frac{1}{8}$ lower than the sides; this forms a $\frac{1}{8}$ lip for the frame ends to rest on. Next nail a plinth of $\frac{1}{2}$ -inch wood, 19½ inches long by 1½ inch deep, for the frame ends to butt against, and to keep in the heat. This plinth will make the ends the same depth as the sides. This hive takes twelve frames. The extra $\frac{1}{2}$ inch in the hive allows $\frac{1}{4}$ of an inch more room to the two outside combs, and makes it easier for the bee-keeper to admit the bees to the supers by the sides of the hive only. A plinth at the sides and back to drop over the sides of the floor-board, as in the case of hives that take standard frames, will make it warmer. The floor board can be made of $\frac{1}{2}$ -inch matchboards, to fit easily within the plinths, and if these are nailed on a batten of $\frac{3}{4}$ -inch and 2 inches broad it will prevent them twisting. Inside the bee house the floor projects about 3 inches. The entrance should be at least 7 inches long, but not more than $\frac{3}{4}$ deep.

FRAMES.

The top bar is 19½ inches long, $\frac{5}{8}$ inch deep, and 1½ inch wide. The side bars are made of $\frac{1}{2}$ inch wood, 8½ inch long, and 1½ inch wide; the bottom bar is 18 inches long and a $\frac{1}{4}$ inch thick, and 1 inch wide. When put together they form a frame of 18 inches by 9 inches outside measure. A groove, $\frac{3}{8}$ of an inch deep and $\frac{1}{8}$ wide, is run out by a plough down the centre of the under side of the top bar. The foundation to be fixed in this groove with melted wax. Make a lug $\frac{3}{8}$ wide, 1½ inch long, and the same depth as the top bar; put one of these on the right hand end of the frame, another on the left, these will keep the frames the proper distance apart. I prefer the frames to hang at right angles to the entrance.

SUPERS.

These are the exact counterpart of the hives, with the exception that they are only 6 inches deep, and the top bar is made of $\frac{1}{2}$ inch wood instead of $\frac{3}{4}$. The frames for the supers are 18 inches by $5\frac{1}{2}$ inches outside measure. Ten frames are used for the supers spaced at equal distances apart; this arrangement gives wider combs, which are so much easier to extract. Supers like those used in hives to take standard frames may be used. Those I have in use are 6 inches deep, made of $\frac{1}{2}$ inch wood, $14\frac{1}{2}$ inches by $15\frac{1}{2}$ inches inside measure, taking a frame $14\frac{1}{2}$ inches by $5\frac{1}{2}$ inches outside measure. A cover for the hive is made of $\frac{1}{2}$ inch wood, and 6 inches deep; the side pieces are $20\frac{3}{8}$ inches long, the end pieces $18\frac{1}{2}$ inches long; if a $1\frac{1}{2}$ inch plinth is nailed round this cover, the plinths having a rabbet $\frac{1}{8}$ inch deep taken out by a half plough, to make them fit easily over the sides of the hive, a flat top completes the hive. It is not absolutely necessary to have this cover, but it protects the hive top from mice in winter and wasps in summer. If a chaff cushion is placed in this cover it will make the hive snug and warm in winter, and the supers cool in summer. In a previous issue "Warwick" asked what hive I most recommended. After considering all things, including going to the moors, wintering and forwardness in spring, I have no hesitation in recommending the above.—GEORGE HOWDEN-SHIRE.

* All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8. Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Book (F. C.).—If you will send your full name and address we will at once send you the desired information.

Seedling Fig Trees (H. S.).—Seedling Fig trees are a long time before they come into bearing, we having raised a considerable number with a view to securing improved varieties, but they were very unsatisfactory as regards showing fruit, and also as to that when produced. Fruiting was accelerated by raising plants from cuttings of the seedlings. For producing fruit for home use or market "seedling Fig trees" are of no use whatever.

Orchid Book (E. K.).—The full title of Messrs. J. Veitch & Sons' work on Orchids is "Manual of Orchidaceous Plants." It is published by the firm, and may be procured from Chelsea, very neatly bound in two volumes, for 5 guineas; or certain parts may be procured, for particulars of which see the firm's seed catalogue. It is one of the most complete and valuable works on Orchids with which we are acquainted.

Peach Shoots and Dead Buds (Cotterell).—Of the nine parts of Peach tree shoots eight are dead in the last year's wood, the two-years wood of one shoot being living, indeed it was the only shoot containing both one and two years growth; the other shoot is quite green, unripe in the wood, and "dead" in the buds. The tree has evidently been badly infested with scale, and dressed with a substance which killed the shoots. The green shoot has not been treated, the white parts are where the scale has been. There are no fungoid growths of any kind, the whole mischief to the wood being caused by the article used to kill the scale, which it has done very effectually, also the Peach tree wood as stated. The buds, however, on the green or live shoot, could not possibly have borne fruit, and perhaps those in the others were in a similar condition before the wood was killed. We can advise nothing but to cut away the dead parts, such as those you forwarded, and thus induce fresh growth from the sound living wood, but probably the tree or trees will scarcely be worth the trouble and delay. Of this, however, you ought to be capable of judging.

Dendrobiums (W. J. P.).—The misdirected parcel only reached us as we are preparing for press. The flowers shall have attention.

Tomato Leaf (Wakopa).—A leaflet 2 inches long and 1 inch broad, withered through being wrapped in dry paper, is entirely insufficient for examination. If you send several leaves packed in a small box with green grass, or something to keep them fresh, they shall be carefully examined. The fragment is excessively flimsy, but whether this is the result of the dry paper absorbing the moisture from it we cannot tell. For hints on packing see the paragraph below headed "Names of Plants." Post specimens on Friday if you can to the address in black type at the head of this column. Sending to Fleet Street involves re-posting, and consequently delay. Mention the temperatures in which you are growing the plants.

The Cucumber Tree (J. S. R. F.).—On previous occasions we have said that this is the popular name applied to *Averrhoa Bilimbi*, a native of Goa and other parts of the East Indies, and is now cultivated in South America. The tree is only 8 feet high, and produces a beautiful green, smooth, fleshy fruit, of the size and shape of a small Cucumber. Rheede says that the fruit when ripe is excellent to eat, but when unripe they are preserved with sugar, or vinegar and brine, and although it should be of an agreeable acid flavour when ripe, yet before they are ripe they are excessively sour. Burman says they contain a grateful acid juice, from which a syrup is made, and a conserve of the flowers, which are esteemed excellent in fevers and bilious disorders. Rumphius seems to think that, even when fully ripened, the fruit can never be eaten raw, but is only used to cook fish, fowl, and other viands, to give them an agreeable acidity, in the same way as we use sorrel and verjuice; they are pickled in brine and eaten as we do olives or capers in conjunction with meats; and preserved in sugar, or with a little saffron, they are recommended to be eaten by those who go sea voyages.

Rust on Chrysanthemum Cuttings (J. V.).—Yes, the leaves are infested with the *Chrysanthemum* leaf-rust fungus (*Uredo Chrysanthemi*), the pustules being very large, and for the most part confined to the under side of the leaf; but there were a few on the upper surface, showing that the germinal tubes from the spores can penetrate through either side when grown relatively soft, as cuttings usually are from the closeness and moisture essential to secure rooting. You will be doing wisely to keep the affected plants from the other stock, and also to wash every leaf with a solution of sulphide of potassium, $\frac{1}{4}$ oz. to a quart of water, applying by means of a sponge, so as to insure the solution coming into contact with the spores in the pustules. The plants should also be dusted from time to time with a fungicide, containing sulphate of copper, in powder on both surfaces of the leaves as made, but this must be done early as a preventive, for with ripe spores in abundance on the older leaves, as in your case, they infest others whilst quite young, but the pustules do not appear until a later period. You must, therefore, kill the spores present, and, as the pustules burst, those following, in order to effect a clearance from the pest, adopting both the preventive and repressive treatment.

Chemical Manure (Chas., Lincoln).—Judging from the guaranteed analysis the manure should be a powerful one, or what is generally termed stimulating, and also of a substantial nature for Vines, Peaches, and Strawberries, using it at the rate of 2 to 4 ozs. per square yard, the larger amount as a first dressing in the spring or at starting, and the other at intervals of about six weeks during growth. Being of an organic nature in the matter of phosphates and ammonia, the manure will prove, or should, of a durable character, hence affording nutrition steadily as the plants require the respective elements—indeed, it is an excellent manure, according to the tests we have subjected it to, and would be very suitable for *Chrysanthemums*, either mixed with the soil in small amount, say, a good handful to a bushel of soil, or applied as a top-dressing in moderate quantity, or at the rate of 2 ozs. per square yard. It is important not to overdo the dressing, especially when applying to plants that have the roots near the surface, and to always exercise judgment in application as indicated by the growth of the plants. It will both "force" weakly things, and also afterwards "encourage steady growth." You may find "The Chemistry of the Garden" useful, as it treats largely on manures and their application.

Ferns from Spores (Fern Lover).—Several of the finest Ferns cannot be increased by division; or, if they can, several years elapse. If right means are followed, they may be raised from spores. This requires a constantly humid warm atmosphere, and little, if any, sunshine. Procure a wide earthen pan, a hand or bell-glass that will go within it and rest on the bottom, and a shallow wide pot, that will stand within the glass and above the rim of the pan 2 inches or 3 inches. Fill this pot half full of potsherds, and upon them sufficient turfy peat, mixed with small pieces of sandstone, about the size of small peas, to come up to the top. Then take the frond of any Fern that is full of spores or seeds, and, with the hand, brush them off upon the prepared pot, set it in the pan, place the glass over the pot, and fill the pan nearly with water. Place the pan in the warmest part of the stove, shading it from the sun. The small pieces of turf and stone can be easily separated, and the seedlings on each put into small pots, without any danger of destroying them by the process of removal. In the moist atmosphere of the Orchid house several species of Fern will come up spontaneously in the pots, baskets, and upon the blocks. These may be carefully detached as soon as they are large enough, and placed in small pots. If kept for a time in a shady situation they will soon make good bushy plants. Ferns require a light open soil. A compost of sandy fibrous peat two parts, turfy loam one part, and leaf mould one part, with a free admixture of sand, will suit them well.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens. Whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (Evans). 1, Bramley's Seedling; 2, Wyken Pippin; 3, Catshead; 4, D'Arcy Spice; 5, Winter Nelis; 6, Olivier de Serres. (Dispter).—Your friend is certainly wrong. The Apple is not Winter Hawthornden, but Bramley's Seedling without a doubt.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (Subscriber).—Each of the Cattleyas is a form of Trianae, and none of them has had a specific varietal name. There are many superior forms in commerce. The other specimen is Pergularia odoratissima. (E. M. C.).—1, Adiantum cuneatum grandiceps; 2, Asplenium bifforme; 3, Lomaria gibba; 4, Prunus Pissardi; 5, Pyrus (Cydonia) japonica. (R. B. R.).—1, A good form of Cattleya Trianae; 2, Sparmannia africana. (A. V. B.).—1, Staphylea colchica; 2, Acacia dealbata; 3, Saxifraga ceratophylla. (Single W.).—Your package was crushed flat when it arrived, and the specimens were quite dead. Send fresh ones properly packed and correctly addressed, in accordance with the instructions at the head of this column, and we will gladly assist you. (Pen and Ink).—Specimen much dried through delay in delivery, consequent on being incorrectly addressed. It is probably Veronica speciosa.

EXPERIENTIA DOCET.

THESE few notes on an egg incubator are from a lady friend. We thought they might be interesting to other poultry raisers.

The impossibility of getting hens which are early and constant layers to sit has been my trouble for some time. Even if I get, as I have done several times, a sitting of eggs from old-fashioned broody hens, either most of the eggs produce cockerels, or the few pullets from the force of bad example object to do the very thing I want of them. Spring after spring have I scoured the country to beg, buy or borrow sitting hens. Sometimes it answers, but as a rule the journey home and the new surroundings all act as a charm, and the most broody hen rarely gives a glance at the eggs. She has been induced to "mother," but on the first chance breaks away and rejoicingly joins her feathered friends in the yard.

As it is a certainty that only early chickens pay, and that late pullets spend a most unprofitable winter, I arrived at the conclusion that, come what might, an incubator I must have. Fortune favoured me. Through the kind offices of a friend I became the lucky possessor of a 100-egg Hearson, in first-rate condition, for the modest sum of £3. These machines new are catalogued at £10. With it were a double set of thermometers, egg testers, and other sundries.

Circumstances over which I had no control prevented my starting the work till January 6th; on that day I filled the copper tank, trimmed the lamp, and anxiously waited results. For successful incubating the drawer tube may register from 104° to 105°, the tank tube 145°. Of course the temperature of the room has to be considered, but with the aid of the book sent out with the machine the beginner soon sees the way quite clearly. The machine soon registered the proper degree of heat, and continued perfectly steady till the evening of January 8th, when the eggs were committed to the drawer. I could not fill the drawer, but put in all that I had, big and little, after having marked them with the date (January 8th).

I had no difficulty whatever with the lamp. The great point is careful trimming and cleaning, and freedom from dust in the perforated parts. It is a wise plan to have a stated time to attend to these little matters, and I do not suppose I vary in my visit to the incubator room ten minutes a week. The machine is in a great bedroom (unused, of course) facing south. Every morning the eggs must be turned and cooled. The time varies from ten to twenty minutes, according to the weather and the stage of incubation.

There is a water tray below the egg drawer, containing perforated zinc covered with a coarse piece of canvas; this must be kept well wetted to supply the necessary moisture to the eggs. Now I read in my book that once a week it would be well to thoroughly scald tray and cloth, to kill any bacteria there might be, so with my kettle of water I proceeded to business; returning the tray immediately to its position below the eggs, I closed the drawer and left.

In about two hours' time I was in the room for some purpose, and to my horror saw the drawer tube stood at 114.1°. The eggs were in a bath of perspiration, and I perspired too. For days the thought haunted me, "had I steamed the innocent embryos to death?" The sequel proved I had done no harm. About the testing on the seventh day. Book in hand I set to work, but so afraid was I of erring on the wrong side that many of the eggs were marked X to denote doubtful. At the fourteenth day I was better up to my work, or rather, perhaps, the eggs, being more advanced, showed themselves more clearly. Now I do not think I should make a mistake of more than 2 or 3 per cent. Those that we removed were perfectly clear and apparently fresh, but I feel sure that some had been subjected to several degrees of frost before being placed in the incubator. This did not strike me at the time, but remembering that all eggs are placed close to a dairy window, which is never shut day or night, I think this fact might account for some failures.

On the evening of the twentieth day there were voices to be heard, and on the twenty-first the drawer presented a lively spectacle. A 100-egg machine is fitted with a drying box, into which the little chirpers were at once placed. A bit of sand makes a clean wholesome flooring. No food should be given for at least twenty-four hours, when the birds will be ready for removal to another sphere. A proper foster mother is costly, so my wits were set to work, and a nice little loose box was rigged up over the hot-water pipes in a greenhouse; the floor was for the most part dry earth, and the plants those homely ones that do not need much water in winter.

Here the chickens lived and thrived, sitting at nights and during dull parts of the day between the hot pipes. A small hole was made out of the greenhouse on to the lawn facing south, and a wire feeder put in front to prevent wanderers straying too far. In this way the birds were hardened till ready to go out to grass (literally), and their refuge then from the night air was a rough box, with a guarded stable lamp in the middle—plenty of ventilation. A friend had lost many chickens by too much coddling; they had what I fancy might correspond to black-leg in calves. They did too well, and were kept too hot.

Now as to food. The first was the rejected egg of the incubator boiled hard, chopped up shell and all, and mixed with fine meal; then all sorts of kitchen bits, and all the milk I could come at; green meat in the shape of parsley, and the trimmings of broccoli boiled; and once or twice a day a handful of small dry rice. Some people advocate little or no drink, but I find chickens will greedily take to milk, and surely Nature is a fairly good guide. There is one little hint to the amateur—do not be in too great a hurry to help the chick out of the shell. Too much interference is fatal. If the skin appears hard and like parchment, I had found it a good plan to hold the egg in warm water; but as a rule those chickens that cannot get out of themselves are never worth much. They are weak in vitality, and the first bit of adversity is too much for them.

These are the chickens that in old days I should have said the careless hen had killed. She is wiser than we, and believes only in the survival of the fittest. I may say, in conclusion, that my common mixed barndoor fowls gave me much better results in the form of

chickens than the well bred fancy eggs I bought. My failures worked out to about 16 per cent., the others to about 60 per cent. Need I say any more?

I mention the failures of the pure strain eggs, because as lately as Saturday last I read some remarks by an eminent Shire horse breeder on the desirability of good sires. He alluded to the supineness of farmers (English) in the poultry yard, and advised the purchase of pedigree cockerels. Now, after much anxious consideration, I have several times been led to the purchase of a first-class bird, only to mourn his premature decease, and in the matter of eggs I think my late experience has been anything but gratifying, the most unsatisfactory being purchased of a man who is a prizewinner, and who fancies himself not a little as a poultry raiser, and the head attendant in the above mentioned gentleman's stud.

WORK ON THE HOME FARM.

Seed time and harvest, summer and winter. So go the seasons, year after year, and Barley seed time is at our door. Barley is a ticklish crop, bad to deal with, and needing attention all the way throughout its career. You are never assured of your success till the maltster's cheque has been acknowledged by your banker. Like other grain, or perhaps more so, the seed has been much improved, and we speak advisedly when we recommend a liberal policy in buying the seed. If Pedigree straight from the raiser cannot be afforded, there are always some farmers more enterprising than their neighbours, and from them good seed may be obtained, second-hand as it were.

Still it is curious, with all the named varieties, to find what a strong hold Chevalier has on our affections. Perhaps it is because it is so well suited to medium and poor soils (we do not all have tip-top Barley land), and also because it may be sown any time.

"Stand well" for real early sowing, and on the land that produces the heaviest crop, is what we should recommend; but the custom of the country is an excellent guide, both as to varieties and time of sowing. March, with its pecks of dust, seems in the course of things the legitimate Barley month. Of course, we have seen March when there was absolutely no suitable seed bed, but as a rule we may depend on the drying winds doing their share of the work. We are always in favour of an early seed time, for in nine cases out of ten the early sown crop proves the best.

It is of the greatest importance that the sheep should have been folded evenly on the previous root crop. A good Turnip shepherd understands his duty, but the master's eye is very necessary. We have so often been able in our experience to trace in Barley fields any neglect of this sort.

It is possible, too, that the land may be made too good—i.e., by the lavish use of cake. If a heavy rain or wind storm comes about the end of June or early July down goes every head, the straw being too long, weak, and sappy. Then, again, it is possible to overdo the seed. Plants must have room for development, and with a good seed bed underneath the Barley will always do its share. We have talked of an early spring and "forrad" season. The migratory birds do not say so. They have come to us at least a fortnight after their usual date, and birds are better weather prophets than most of our savants.

We have been surprised to learn that we are recommended to use the light two-horse drill in place of the cumbersome machine that required four horses. Now, is not this advice a bit late in the day? We have not met with such a drill for many a long day; indeed, we expected all such had long ago been broken up for the sake of what old iron they contained and the rest used as "kindling."

REMARKS.

- 6th.—Fine and pleasant, but no very bright sunshine; clear night.
 7th.—A little sleet early; brilliant from sunrise to noon; cloudy after, and slight snow after 3 P.M.; overcast evening.
 8th.—Bleak, windy, and overcast day; bright sunset.
 9th.—Overcast day; gleam of sun towards sunset.
 10th.—Brilliant morning; fair afternoon, with a little sun after 4 P.M.
 11th.—Overcast morning; fair afternoon, with occasional sunshine.
 12th.—Overcast morning; fair afternoon; fine night.
 Another cold week, temperature very uniform, and no rain.—G. J. SYMONS.

BARR'S PURE GRASS SEEDS

Produce Beautiful Smooth Lawns.
Tennis Lawns, Cricket and Croquet Grounds.

THE FOLLOWING MIXTURES OF GRASS SEEDS are all thoroughly cleaned, and cannot fail to give the greatest satisfaction. There are neither Clover nor coarse Grasses in "OUR MIXTURE OF GRASSES." The seed is sold by weight, being the only correct method of estimating quantity needed for a given space:—

Barr's "Thames Embankment" Grass Seeds for Parks.—A special mixture, which has been found very successful in many public and private parks and squares around London and throughout the country. Per lb., 1/3; per 10 lb., 11/6; per 20 lb., 21/-.

Barr's "Standard" Grass Seeds for Garden Lawns, Golf Links, Cricket Grounds, &c.—In this mixture there is a larger quantity of dwarf, fine-leaved Grasses than in Barr's "Thames Embankment." Per lb., 1/6; per 10 lb., 13/6; per 20 lb., 25/-.

Barr's New Mixture of Dwarf Grasses for producing an extra fine smooth Lawn.—A special mixture of the finest-leaved and dwarfest-growing Grasses, producing an EXTRA FINE VELVETY TURF, and saving labour in not requiring frequent mowing. Per lb., 2/-; per 10 lb., 19/-; per 20 lb., 37/-.

BARR'S SEED GUIDE, containing a Descriptive List of the best Vegetables and most beautiful Flowers, free on application.

BARR'S HARDY PERENNIALS & ALPINES.

NOW READY.—BARR'S ILLUSTRATED CATALOGUE, With full descriptions of all the best Hardy Perennials and Alpines, and many useful notes on culture, free on application.

DAHLIA ANALYSIS, 1883-97.

THE exhibition of the National Dahlia Society, which took place at the Crystal Palace in September last, was the largest the Society has yet held. It was not only in one or two sections that there was an unusual number of exhibits staged, but in nearly every section the classes were well filled. The growing season of last year, although again very dry, was not nearly as warm as in the same three months, May, June, and July, of the previous year, which no doubt made it less trying to the young plants. The cooler weather of August, and the frequent rains which fell during that month, caused the plants to make rapid growth; while September also proved very favourable. The most remarkable feature of the season, however, was the long period that Dahlias continued to grow and flower freely in those localities where they had been so fortunate as to escape the October frosts. Indeed, in many places excellent flowers were to be gathered even as late as the middle of November. In my own garden they passed through 5° of frost on the night preceding the 6th of October without the slightest injury, only to fall victims to 8° of frost on the following night. I could not understand this at first, as both nights were equally clear, calm, and dry, but afterwards found that the temperature on the first night had remained at its lowest point only about a quarter of an hour, whereas during the second night the greatest cold was steadily maintained for nearly six hours. The frost referred to completely destroyed the upper half of my Dahlias, and checked their flowering for the rest of the year; but they were not cut down to the ground until November 19th, which is eighteen days later than the average date of their destruction in the previous twelve years, and with the exception of 1894, the latest recorded here during that period.

The Shows and Fancies appeared in unusual force, reminding one of the exhibitions of ten or twelve years ago, when they formed the principal attraction of the exhibition. In fact we have to go back to 1888 in order to find these two sections, when taken together, as well represented. The

Pompons also appeared in unusual force, while the Cactus varieties have never before been as well or as numerous shown. The introduction of this popular type, and the great improvement that is being made in it year by year, has undoubtedly given the Dahlia a fresh lease of life as a flower, whether for exhibition purposes or for ordinary garden decoration, and has at the same time considerably added to the general interest in its cultivation.

The following short table will show the number of blooms and bunches set up in competition at the last five exhibitions of the National Dahlia Society, and will serve to confirm the remarks that have previously been made as to the extensive character of the last show held by the Society.

	1893	1894	1895	1896	1897
Shows (No. of blooms) ...	720	894	827	798	930
Fancies " " " " " " ...	270	301	287	276	312
Pompons (No. of bunches) ...	168	192	210	192	234
Cactus and Decorative (No. bnchs.)	264	246	280	220	432
Singles (No. of bunches) ...	128	138	102	126	116

In the above statement the number of flowers staged in the classes set apart for three or more blooms of any variety is not included.

It is now twelve years since Mrs. Gladstone assumed the lead of

the Show Dahlias in this analysis, and during the whole of that period its position as the premier variety has never been seriously threatened. At several exhibitions either John Walker or R. T. Rawlings have been more numerous staged, but the more consistent form of Mrs. Gladstone has enabled it to maintain the decided advantage it secured at the time of its first appearance over all its rivals. John Walker, owing to the comparatively small number of stands in which it appeared at the last show, has had to give up the second place on the list in favour of R. T. Rawlings, which was more largely shown than in any previous year—in fact, exactly the same number of times as the leading flower. William Rawlings and Mrs. Langtry, both very dependable varieties, were also unusually well shown. Among other varieties which were last year staged more frequently than usual may be mentioned Harrison Weir, Miss Cannell, Glowworm, Mr. Glasscock, and Victor.

On the other hand, we have to go back to the year of its introduction in order to find John Walker as poorly represented. Harry Keith, James Cocker, Ethel Britton, John Hickling, Willie Garratt, Henry Walton, Prince of Denmark, and Goldfinder, to say nothing of other varieties lower down on the list, were but indifferently shown.

SHOW DAHLIAS.

Position in Present Analysis.	Average Number of Times Shown.	No. of Times Shown in 1897 in True Relative Proportion to the Average.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	35.9	32	Mrs. Gladstone	1884	Hurst	Pale blush

48	5.5	8	Virginale	1893	Keynes	Blush white, edged pink
49	5.0	3	Norma	1894	Turner	Bright orange buff

* New varieties, the positions of which are dependant on their records at the 1897 show only.

Turning now to the newer kinds, those sent out during the last six years, we shall find that valuable new blood has been infused into this section during that period, and that no fewer than six of these new Show Dahlias are to be found among the first twenty-five in the table. The year 1892 is responsible for four of the sorts which are so placed. John Walker, although last season appears to have been very unfavourable to this grand white variety, occupies the third position on the list. Arthur Rawlings still remains at No. 10, while William Powell stands at No. 21, and Arthur Ocock at No. 25. The variety last named would occupy a higher position than it does but for its bad form at the two last exhibitions. The Show Dahlias sent out in 1893 have failed as yet to make their mark, Mrs. Morgan only taking a place at No. 35, while Virginale on its first appearance in the table will be found at No. 48. Duchess of York (No. 6), although only distributed in 1894, promises well, only four other varieties having been better staged at either of the last two shows; while Chieftain of the same year takes up an honourable position at No. 27. Norma, however, only manages to creep in at the end of the list. Shotesham Hero (No. 10) the only representative of 1895, was remarkably well shown, and, depending on its last year's form alone, stands higher in the list than any of the other new sorts, except John Walker and Duchess of York. 1896 is also represented by only one variety, Florence Tranter, which makes its *début* at No. 27.

The race for first place on the table of Fancies between those two veterans, Rev. J. B. M. Camm and Mrs. Saunders, which had been maintained for a number of years, may now be regarded as at an end. Previous to 1895 the latter held the lead, but since then Rev. J. B. M. Camm has been gaining steadily upon its rival, and at the last exhibition was staged oftener than at any other time during the fifteen years covered by the analysis, and also more frequently than any other Show or Fancy variety except Mrs. Gladstone and R. T. Rawlings. Surely this must be regarded as a remarkable performance considering Rev. J. B. M. Camm has now been in cultivation for exactly a quarter of a century. Both Duchess of Albany and Mrs. John Downie were unusually well shown, also Dorothy and Buffalo Bill. But comparatively few flowers were staged of Mrs. Saunders, Frank Pearce, T. W. Girdlestone, and Rebecca.

The newer sorts in this section, those distributed within the last six years, are few in number, and none of them occupy a higher position than No. 11. The only representative of 1892 is Comedian, which was poorly shown last year, and consequently falls from No. 9 to No. 12. Dazzler, sent out in 1893, remains pretty well as before, at No. 18. Of the 1894 varieties Emin Pasha rises from No. 14 to No. 11, while S. Mortimer (No. 14) has never been quite as well represented as during the first year after its introduction.

In the section devoted to those miniature Show and Fancy Dahlias known as Pompons, many of which are so admirably adapted for the purposes of garden decoration in the early autumn, the changes are much more rapid than in the two classes previously dealt with. For instance, of the twenty-five varieties named in the select list which follows, only about half the number were last year more than five years old. Of these, which may be termed the established varieties, Phoebe was more largely shown at the last exhibition than in any previous year. Whisper follows at some distance with a very steady record for the past eight shows. E. F. Junker has also proved itself dependable, although less frequently staged than formerly. Eurydice, on the other hand, has improved its position during the last five years. Isabel, Darkness, White Aster (Guiding Star), Favourite, Red Indian, Grace, and Mars appear, however, to be gradually declining in favour with exhibitors. The most striking advances made in the newer kinds, those sent out since 1893, are shown by Nerissa (1896), which rises from No. 7 to No. 2; while Emily Hopper, Douglas, Ganymede, Rosebud, and Sunny Daybreak all occupy good positions considering that they appear for the first time in the list at all.

There are still several Cactus Dahlias, which last year were more than two years old, that continue to hold their own among the newer sorts. For instance, Matchless again takes the premier position in this section, having been staged more frequently than any other Cactus at the last three exhibitions; while Gloriosa, Lady Penzance, Delicata, Bertha Mawley, and Robert Cannell are also to be found among the first twelve on the list. If we take the Cactus Dahlias of more recent introduction in the order of their ages, we find that of the varieties sent out in 1895 Earl of Pembroke stands only second to the leading flower—Matchless. Harmony remains in its former position at No. 7, while Mrs. Barnes has fallen from No. 6 to No. 9. Fusilier (No. 5) takes the lead of the 1896 varieties, followed by Mrs. Wilson Noble at No. 8, Beatriee at No. 13, J. E. Frewer at No. 15, and Miss A. Nightingale at No. 20. Two of the sorts sent out in 1897 also find places on the list—viz., Starfish at No. 16, and Harry Stredwick at No. 19.

When we come to treat of the single-flowered varieties, the limited number of exhibits in this section is undoubtedly a drawback in placing them accurately. I have, however, treated them in precisely the same way as the Cactus varieties. Victoria still takes the lead, followed by W. C. Harvey, of the same year, 1889. Of the other established varieties Miss Roberts, Northern Star, and Amos Perry occupy the best positions; whereas the most prominent of the newer kinds, those sent out since 1893, arrange themselves as follows:—Demon, Phyllis, Beauty's Eye, Polly Eccles, The Bride, and Jack Sheppard.

FANCY DAHLIAS.

Position in Present Analysis.	Average Number of Times Shown.	No. of Times Shown in 1897 in True Relative Proportion to the Average.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	20.9	27	Rev. J. B. M. Camm	1873	Keynes	Yellow and red
2	18.7	11	Mrs. Saunders	1872	Turner	Yellow and white
3	17.7	20	Duchess of Albany	1884	Turner	Orange and crimson
4	17.0	19	Mrs. John Downie	1889	Turner	Orange and scarlet
5	14.7	13	Matthew Campbell	1889	Keynes	Buff and crimson
6	14.4	11	Frank Pearce	1886	Rawlings	Rose, striped crimson
7	13.8	6	T. W. Girdlestone	1890	Keynes	Lilac and maroon
8	12.7	15	Dorothy	1888	Keynes	Fawn and maroon
9	9.8	10	Peacock	1877	Turner	Maroon and white
10	9.6	11	Buffalo Bill	1890	Keynes	Buff, striped vermillion
11	9.5	11	Emin Pasha	1894	Keynes	Yellow, striped crimson
12	9.3	7	Comedian	1892	Keynes	Orange and crimson
13	8.6	6	Rebecca	1883	Keynes	Lilac and crimson
14	8.0	6	S. Mortimer	1894	Mortimer	Rose, striped crimson
15	6.8	4	Henry Eckford	1886	Rawlings	Yellow and red
16	6.7	6	George Barnes	1878	Keynes	Lilac and crimson
17	6.0	5	Dandy	1891	Keynes	Orange, striped crimson
18	5.0	3	Dazzler	1893	Keynes	Yellow, striped scarlet

In the following select lists the Pompons have been dealt with in a similar way to the Shows and Fancies in the tables. In the case of the Cactus and Single varieties, however, the average number of times they were staged at the last two shows alone governs their relative positions in the lists. Those marked with an asterisk are new sorts, the positions of which are dependant upon the number of times they were shown at the last exhibition only.

POMPONS.—Bacchus, Nerissa,* Phoebe, Tommy Keith, Arthur West, G. Brinckman, Captain Boyton, Whisper, E. F. Junker, Eurydice, Admiration, Isabel, Emily Hopper, Douglas,* Ganyinede,* Lilian, Rosebud*, Sunny Daybreak,* Darkness, White Aster (Guiding Star), Sunshine, Favourite, Red Indian, Grace, and Mars.

CACTUS.—Matchless, Earl of Pembroke,* Gloriosa, Lady Penzance, Fusilier,* Delicata, Harmony,* Mrs. Wilson Noble,* Mrs. Barnes,* Bertha Mawley, Mrs. Peart,* Robert Cannell, Beatrice,* Mrs. A. Beck,* J. E. Frewer,* Starfish,* Countess of Gosford, Juarezii, Harry Stredwick,* and Miss A. Nightingale.*

SINGLES.—Victoria, W. C. Harvey, Demon, Miss Roberts, Phyllis, Beauty's Eye,* Northern Star, Polly Eccles,* The Bride, Amos Perry, Jack Sheppard, James Scobie, Gulielma, May Sharpe, Miss Glasscock, Mrs. Wythes,* Duchess of Fife, Miss Henshaw, Mrs. Parrott, Rosebank Cardinal, and M.C.C.—E. M., *Berkhamsted*.

NAMES AND KINDS OF CARNATIONS.

(Concluded from page 234.)

THIS dynasty of Dutch Carnations bore sway from about 1680 till 1740, when they were suddenly dethroned by the introduction of French flakes, which were more generally known as Whole Blowers, because the flowers did not, like the "Bursters," burst open their pods. A split pod was, in fact, so much a fault that the more expert growers have been known to fill up the slit with a piece of green silk the same shade as the pod itself. A bloom 3 inches in diameter was considered a sufficiently large size. The petals were still serrated on the edges, but instead of being inflected, they were "plain and circular like the leaves (petals) of a Provence Rose." Hence these petals were called Rose-leaved. About 1780 the petals lost their "jagged" edges, and at the beginning of this century, from many coloured engravings, we know that the florists' Carnation had attained a condition of comparative perfection. The Mr. Pearson, of Chilwell, of that day, was a famous raiser of seedlings, and later, about the forties, Dr. Horner was a leading grower, and raised many fine varieties, including yellow Picotees. Self-coloured flowers are rarely heard of, though at some of the exhibitions prizes were offered for them. On the Continent many self-coloured flowers are noted, and in great variety, about the beginning of the century.

In cultural matters the old growers differed in some items from present day cultivators. For example, they layered their stock at the earliest possible moment. From the "end of June till the end of July" is recommended as the time to be preferred. Some cultivators of the present day have discovered that early layering is an important matter, and as its value as a factor in obtaining healthy plants becomes more generally recognised, no doubt the practice will become general. Then the old growers were most particular in putting down short growths only. One writer says "two joints" is sufficient; others agree that three, or at most four, is a proper number. But for bedding out there is nothing gained in taking short layers. So long as they are not *hard* I have no objection to their length, as the production of flowers from these is so much greater.

Another long-established usage was the removal of the tips of the foliage. Maddocks shows a layer ready for pegging down, every leaf of which is cut hard in. It is a practice, so far as my experience goes, more honoured in the breach than the observance. Then the composts! Hogg's is five of loam, ten of horse manure, one of coarse sand. A hundred years earlier two of loam to one of neat's manure was the proportion. Glenny, who was Hogg's rival, employed a compost much like the last. No wonder the plants were often unhealthy and difficult to keep!

It is a curious fact, that from the earliest notices we have of the Carnation onwards till the present day, the "finest" sorts have been cultivated in pots, and protected during the months of winter. Dryness, both at the root and in the atmosphere, has also been considered essential, alike to the health of the plants as well as for the ripening or maturation of the stems for flowering strongly. Early spindling, through exciting treatment, is fatal to success. This has always been guarded against, and it can only be assured by dryness

and coolness, or, when grown in the open, by reducing to the lowest limit the chance of moisture doing harm.

The question of scent in Carnations is one that has always, or at least for a very long period, exercised lovers of this flower. The old-fashioned plan of "laying bruised Cloues round about their rootes" was simplicity itself; but though assured that this was a certain method to "make Gilliflores smell like Cloues," who nowadays so bold as put it to the test? As a matter of fact it was only a few varieties among many that at any period were possessed of the true "spicey" scent of Cloves; such, for instance, as we find at present in the old Malmaison or in Buccleuch Clove.

It was assumed by some that a deep red colour, whether the flower was a self or the colour laid on in stripes or in spots, was essential to any variety yielding the true Clove scent. When, however, we can turn to Lady Nina Balfour or to Mons. Magny as examples of flowers without any trace of crimson possessing a Clove scent, it will be seen that crimson is not essential. A point worthy the attention of raisers is whether it is well to discard every flower that does not reach the standard that for so long has been received as the one to aim for. Lady Nina Balfour, if treated with the severity due to her ragged petals, would on no account be grown, nor would Ruby, Vivid, Alice, nor even Duchess of Fife. The truly wonderful changes which the Carnation has, under the hands of enthusiasts, passed through, are warrant that we may yet have our gardens rich in Gillyflowers perfect in habit of growth, free-flowering, and in not a few with the Clove scent fully developed.—R. P. BROTHERSTON.

COUNTY COUNCIL TRIALS IN SURREY.

HAVING recently noticed what is being done in Worcestershire in the matter of fruit and vegetable trials, there can be no harm if I briefly refer to those which will be conducted in Surrey this year. We have no central garden. We rather prefer to play the part of Mahomet and go to the mountain, or in other words the people interested in garden trials. These are specially, though not absolutely, the allotment holders. For that reason our trial grounds are ordinary allotment plots situated in prominent positions on groups of allotments, four in number, in different parts of the county. In such positions the allotment holders can see, from sowing and planting till the clearing of the crops, all that takes place, and as every separate crop or variety is legibly named, each person may be as wise as those who cultivate and crop.

The chief trial plot this year will be that at Surbiton. This is on one side of the main entrance to the District Council's fine area of some 200 plots, all let, and generally well cultivated. We see in this area how allotments are appreciated. The trial plot is faced along beside the entrance road with a neat flower border 3 feet wide, now planted with a fine lot of seedling Carnations raised from Mr. J. Douglas's strains, also with Pansies, Polyanthus, white Columbines, and other hardy plants, and there will presently be sown also annuals to furnish additional summer beauty. The ground behind is about 27 feet wide, and having been trenched the previous winter, and well manured, has lately been dressed with lime sludge from sewage works, then deeply dug, and later farther dressed with superphosphate of lime and kainit at the rate of 4 lbs. per rod. Twenty of the leading varieties of Potatoes, several being quite fresh, will shortly be planted thinly in rows 30 inches apart, and nineteen varieties of Peas, dwarf and medium height, have been sown. These include the very best varieties of wrinkled Marrows, generally of about 3 feet in height, that could be obtained. There will also be sown the best varieties of Dwarf Kidney Beans, including two not yet in commerce; also Scarlet Runners and Longpod Beans. Most of the varieties are little known to the allotment holders, and their development will be closely watched. After all the various crops are well through a dressing of sulphate of ammonia will be given over one half of each row and an equal dressing of nitrate of soda over the other half. It is in this way hoped to ascertain to some extent which of these two famous nitrogenous manures seem to be the more fertilising.

The trial plot at Richmond is situated in a prominent position in the centre of the fine group of Corporation allotments, a group that is second to none in the county. The soil is light and porous. Having been dressed with animal manure and deeply dug, one half has been sown with numerous good varieties of Peas, several rows to lie on the ground, and others of the same varieties, with various others, to be staked. It is hoped that the value of staking Peas, where stakes are dear, will be fully evidenced by the greater produce found on the latter rows. The other half will later be sown with several fine varieties of Onions, Beets, and Carrots, all the best strains being secured for this purpose. The relative values of nitrate of soda and sulphate of ammonia as dressings will also be tested.

The ground at Bookham, some 24 rods in area, kindly presented by Mrs. Chrystie, will be utilised for growing Peas and Potatoes for continuation school gardens. This ground being rather poor has lately been dressed with animal manure. One half has been sown with some half dozen useful Peas, such as The Daisy, Senator, Prince of Wales, Dr. Maclean, Magnum Bonum, and one or two others; the other half will be planted entirely with Potatoes. Later on half, longitudinally, of each side will be dressed with sulphate of ammonia. The lesser area of ground at Egham, which is very sandy, will be used for a trial of Dwarf French Beans and some Potatoes.—A. D.

CATTLEYA MIRANDA.

PROMINENT among the many beautiful Orchids that were staged at the Drill Hall on March 8th was *Cattleya Miranda*, which was shown by Messrs. J. Veitch & Sons, Ltd. It is a hybrid resulting from a cross between *C. guttata* Prinzi and *C. Trianae*. The flower is very handsome in both form and shape, and was much admired. The prevailing colour of the sepals and petals is soft rose, but the broad petals are splashed with crimson. The fimbriated lip is deep velvety crimson with a peculiar suffusion of violet. The woodcut (fig. 54), depicts this beautiful hybrid, which received an award of merit from the Orchid Committee of the Royal Horticultural Society.

CYCNOCHES.

THE Swan-neck Orchids, as they are generally called, are not very popular; indeed, if we except one species, *C. chlorochilon*, it is unusual to see any of them in collections. This is a great pity, for few Orchids are more interesting, and they possess a good deal of beauty. The genus takes its popular name from the gracefully curved column, which is more marked in some kinds than others, but peculiar to them all. Although of very rare occurrence, under cultivation most of the *Cycnoches* have the habit of producing two kinds of flowers upon a plant, the male and female.

So different in appearance are these, that at one time they were thought to belong to separate species, but when a plant flowered under cultivation bearing the different flowers it was evident that they belonged to one and the same kind. The culture of *Cycnoches* does not present any great difficulty, and success or failure depends more upon careful attention to details than to any peculiarity of the plant. When these are newly imported they have the appearance of a thick mass of half-dry sticks, no green foliage being apparent, and the colour of the bulbs being almost hidden by the whitish scaly remains of the old foliage. To look at these one would say that they possessed little value, but a short time in a warm moist atmosphere soon plumps them up, and apparently brings them back to life.

When all traces of shrivelling are gone, and young shoots begin to appear at the base, the bulbs may be potted or basketed principally in clean crocks; but established specimens like a fairly substantial compost, a little loam fibre mixed with the peat and moss being useful for the stronger plants. Good drainage is essential in all cases, and this must be protected by placing thereon a little of the rougher part of the sphagnum or peat fibre. Let the leading pseudo-bulbs just rest on the top of the compost, but avoid burying them. Then when the large, fleshy roots appear they enter the new material at once, to the advantage of the forming flowers and pseudo-bulbs.

The safest time to repot is when the young growths are starting, but none of the species likes disturbance, and should be returned to their growing quarters without delay. This should be a well-heated, moist, and light house, where the plants can be exposed to the full sun in winter, but sufficiently shaded in summer to prevent injury to the somewhat tender foliage. But for this being so easily scorched, the plants would do far better in baskets suspended from the roof than in pots a yard or more away on the stage.

Water sparingly at first, but when the new roots are running freely in the compost a full supply is required. The foliage would be all the better for frequent light dews from the syringe, but the water is apt to collect in the centre of the growth and cause this to decay. In summer, when moisture is freely used about the house, it is a good plan to turn each plant upside down for a few seconds in the morning, this allowing any water that has collected to escape. Towards the end of the summer the new pseudo-bulbs will be fully made up, and soon after this the root moisture may be somewhat lessened.

The foliage soon after begins to lose its colour preparatory to the plants going to rest, and they may then be hung up or placed on a

light stage where the sun reaches every part of them. The most frequent mistake made with this deciduous class of Orchids is allowing the roots to get dry too quickly, thereby starving the bulbs just as they need the most support. Ripen them thoroughly first, then rest them by withholding both heat and moisture to a certain extent. The pseudo-bulbs will then keep plump all through the winter and early spring, though they get scarcely a drop of water, and the young growths resulting will be all the stronger and more vigorous for the long rest.

C. aureum is one of Mr. G. Ure Skinner's introductions from Central America, and bears pendulous racemes of pale yellow flowers. It is not so well known as *C. chlorochilon*, which is without a doubt one of the finest in the genus. The pseudo-bulbs are about a foot high, and bear many-flowered racemes, the blossoms varying considerably in size. The largest are more than 6 inches across, but the smaller the individual flowers the more of them are produced on the racemes. The ground colour of the flower is a pale yellow

FIG. 54.—CATTLEYA MIRANDA.

with just a suspicion of green, and there is a large dark blotch under the column. It was introduced to this country by Messrs. Loddiges of Hackney, who imported it from Demerara in 1836.

C. maculatum is a rare but distinct species, a native of Mexico, and sent by its discoverer, Mr. Ross, to Mr. Barker of Birmingham. A fine plant I noted recently had a flower spike about 15 inches in length, closely covered with the yellowish flowers, spotted with crimson and purple. It first flowered in this country in 1839. *C. pentadactylon* is a fine species introduced by Messrs. Veitch when at Exeter, in 1841. It comes from Rio de Janeiro, and was discovered by their collector, Mr. W. Lobb. The blossoms are produced on many-flowered racemes, and are prettily spotted with reddish brown on a yellow ground. It is one of the brightest of all the known kinds. —H. R. R.

THE CROCUS SEASON.—The displays of Crocuses this season appear to have been good, lasting over a longer period than usual. The mild weather in early February brought the bulbs into bloom, after which cooler weather and the absence of strong sunshine prevented them expanding fully, causing the flowers to be preserved in excellent condition up to the present time. Unfortunately, birds attack the yellow flowers often strewing the ground with detached petals.—E.

AMONG THE HARDY FLOWERS.

ONE of the drawbacks to spring gardening is the occurrence of late frosts. This year such was the mildness of winter that we were in hope that these would be spared us, though past experience made us mingle the hopes with doubts. These fears have been justified, and, as this is written, night frosts are not only frequent but of great severity. They are trying to the young growth of many plants, and, with the brilliant sunshine which follows, shorten and deface the beauty of numerous flowers. On a recent morning everything was powdered over with rime, and as one went round the garden it was easily seen how keen the frost had been. Many of the Daffodils and Snowdrops were almost prone; the Water Lily pools were sheeted with ice, and the gold fish within were seen as through a window; Scillas, Chionodoxas, and other flowers were frosted, and looked beautiful with their silvering. Especially pretty was Chionodoxa Alleni, which seemed as if it had been carved out of some coloured substance, and then silvered over, but not so deeply as to hide the colouring below. As the sun gathered power these things changed, and the flowers resumed their wonted appearance. Yet the inclemency of the nights leaves its mark upon the blossoms. Colours are dimmed, and their brilliancy greatly reduced, so that it has become profitable to cover many of the plants in flower in some temporary way at night. Extemporised coverings do much, but the possession of a few hand-lights and glass shelters is found a great advantage in such a season. Put on at nightfall, and removed when the sun shines through the frosty air, these shelters will soon repay themselves by the longer and brighter display they give, although they cannot so well be employed for large masses of flowers.

As usual it is to what are broadly known as bulbous plants that we are principally indebted for flowers in March. There is no lack of these, and those who embark upon the cultivation of the less common genera, or species and varieties, will find much true pleasure in its pursuit. Daffodils are, however, widely grown, though one can hardly call them "common" in the restricted sense of the word. Despite the prominence given to them by the gardening press and the efforts of specialists, it is surprising to find how limited a number grow any considerable variety; how few are acquainted with some of the more modern introductions, even those procurable almost as cheaply as the older standard varieties. One is led to this remark by finding how much the pale early Daffodil—*Narcissus pallidus præcox*—is noticed and admired when seen in gardens. It is cheap enough, and in light soil and in a sunny place has been quite a success for many years. Seedlings raised from it are now coming into bloom, and are showing evidence of the work of the bees in carrying pollen from some other Daffodils. One of these appears to be the little *N. minor*, one seedling showing the size and perianth segments of *pallidus præcox* with the trumpet—but enlarged—of *minor* both in form and colouring. The majority of the Daffodils have yet to flower, but with the exception of the magnificent *N. telamonius plenus*, there is every prospect of a floriferous season, which will give delight to the lover of the Daffodil.

Ever admired also, and quickly growing in favour, is the Glory of the Snow. *Chionodoxa sardensis* was the first to flower, but though the greater number of plants of this species are in bloom, there are individual bulbs just pushing their points through the surface of the soil, so that the season of bloom will be a long one. One good form, received as "*C. grandiflora*" some years ago, when the latter was introduced, proved to be a fine variety of *sardensis*, and, as it has increased since it came, has been much admired in its place in the rock garden. *C. Alleni*, *C. grandiflora*, and *C. Lucilæ* are now represented among flowers in bloom, but the majority of these species are not in flower, though a few days will bring them to perfection. *C. Timolusi*, about which there has been some difference of opinion, is the latest to flower, and is not yet through the ground. None is more beautiful than the exquisite *C. Lucilæ alba*, though I expect it will be less regarded when *C. Alleni alba* comes into bloom, as it will do shortly. It may be of interest to remark that seedlings of the white variety of *C. Lucilæ* give a very small proportion of white flowers. There do not seem to be 1 per cent. among a considerable number coming into flower in my garden.

Scillas naturally claim some notice now, so pleasing are they with their bright flowers. Whether we look at the fine "bells" of *S. sibirica* or the smaller flowers of the varieties of *S. bifolia*, we cannot but recognise their beauty. In connection with the latter I have before mentioned Mr. Allen's seedling, named Pink Beauty, and I have now to mention another from the same source, named White Queen. This is of purer white than the ordinary white form of *S. bifolia*. It has also larger flowers, with broader segments. Although not at present procurable from trade sources, White Queen is mentioned with a view to interest others in the work of improving our early flowers.

Snowdrops are not yet over, and some may think they have been

long enough with us for the year. All are not of the same mind, and thus two or three of the later species or varieties may be named. Obtainable from some trade sources, and although not of the first rank in size, yet valuable for its time of blooming, is a variety of *Galanthus nivalis* named *æstivalis*, which I have not spoken of for a good while. It is small in size, and not so perfect in flower as many. Then we have *G. Gusmisi*, still in bud on 8th March. This is not plentiful, but I have seen it occasionally offered. It appears to be a variety of *G. caucasicus*. *G. Ikariæ* grown in shade is also lasting long in bloom, and is much finer in that position than in sun, its fine broad green leaves and pure bells being much more impressive. This year the varieties of *Iris reticulata* are flowering very badly; the only satisfactory one is *I. reticulata major*, a handsome flower with deep blue colouring, with a dash of white and gold in the centre. The failure of some of the others to flower makes one afraid that the disease to which these Irises are subject may have obtained entrance into the garden.

As usual, other flowers can only be incidentally mentioned now. The singular and beautiful *Narcissus cyclamineus major*, the rare *Crocus Sieberi versicolor*, *Hyacinthus ciliatus amphibolis*, all deserve a note to themselves. In the crowd of other things now coming on they may be overlooked. Grape Hyacinths show colour, *Arabis* grows daily whiter with bloom, *Aubrietias* begin to purple over, and the number of blossoms on the *Primulaceæ* increases rapidly. *Iberises*, too, show great progress, and despite the chill nights flowers hasten to fulfil their annual mission—a haste we who care for them think all too slow.—S. ARNOTT.

VEGETABLES FOR HOME AND EXHIBITION.

BRUSSELS SPROUTS.

ONE need not enlarge on the usefulness of Brussels Sprouts as a winter vegetable. No other member of the Cabbage family possesses the same flavour as the firm knobs which are the result of a good strain and good cultivation. From an exhibitor's point of view Brussels Sprouts come in only for the late autumn shows, and if shown on the stems it is not necessarily the largest that are the best, but those furnished thickly all the way up with sound firm knobs. For producing sprouts of this character varieties dwarfed in habit are preferable to those growing large, though if quantity is the object in view the latter are the better to grow.

From the end of October to April is the season during which we look to the Brussels Sprouts quarter to provide vegetables for the kitchen. Generally speaking the best results are obtained by giving the plants as long a season of growth as possible, in order that they may attain their full size and strength before the growing season is over and the winter sets in. Early sprouts being often in demand, the first sowing should be made under glass in February, followed by a second in a warm position outdoors in March. The first sowing may be made thinly in shallow boxes, or on a bed of light soil in a frame. A great deal depends on thin sowing, and it is easy to see the difference in result between plants that are weakly and drawn through having been huddled together in the seed bed, and dwarf sturdy specimens, full of health and vigour, that are obtained through thin sowing and early transplanting.

Though there are advantages in raising early, these are lost if there is any coddling or undue forcing. As the seedlings grow air must be admitted freely to harden them, and when large enough they should be transplanted either close to the glass in a cold frame, or in a bed of rich soil in a sheltered position outdoors, dispersing them at a distance of 6 inches apart. In order that they will lift with good balls for the final planting a little old Mushroom bed refuse may be incorporated. The second sowing should be made outdoors on the same lines as the first, the surface of the bed having been made fine, and the seeds covered thinly with old potting soil. Sprinkling the ground with fine wood-ashes often acts as a preventive against club-root trouble. Do not leave the seedlings to become crowded in the seed bed, but transplant as before, so that the vegetables from beginning to end may have a fair chance, and are subject to no check that can be avoided.

Attention must be paid to the preparation of the ground for the final transplanting, and though the advice to plant quarters as they become vacant with winter vegetables is good enough in the abstract, the soil and position for this important crop should have careful attention. Brussels Sprouts are gross feeders, and the soil must therefore be enriched with farmyard manure, more particularly so if it is of a light sandy nature, and not of the character to hold much moisture. Fairly strong soil of firm texture is the most suitable for the crop, and if it has not been in use for some time previous the top spit should be turned over and the next dug in the trench, incorporating with it some good manure. By this means the ground is worked and enriched to a depth of from 18 inches to 2 feet. Soil that has been subject to frequent manurings is improved by a dressing of lime.

The end of May and early in June are good times to make the final transplantings, this allowing for a long season of growth, and the distance apart must vary according to the variety. If due care has been taken with the plants in their seedling state they will be strong and sturdy, and lift with good balls of earth attached. If the weather be dry they should be well watered the day before transplanting. Brussels Sprouts may be removed in any weather if in good condition, and if the ground be dry a thorough watering will settle the soil round the roots, and there will be little or no flagging afterwards. The after cultivation consists in frequently moving the surface soil with the hoe, which conserves the moisture during dry hot weather, and when the plants are growing strongly applications of liquid manure from the farmyard may be given with advantage.

When the sprouts are formed and pulling commences all decayed leaves should be removed from time to time, but I fail to see the advantage of the wholesale cutting of the leaves which is often practised, as in the ordinary course of Nature this mutilation must have a detrimental effect on the plants. The terminal head is different in flavour from the sprouts, and should not be removed till the latter have been gathered, as in severe winters it forms a protection from frost. There are numerous varieties of Brussels Sprouts in cultivation, of which Northaw Prize, President Carnot, Matchless, Scrymger's Giant, and Sutton's Gem are amongst the best. — GROWER AND JUDGE.

TEN MINUTES' NOTES.

IN order to diversify these notes I contribute a trio on kitchen garden crops, as being seasonable, with a pendant on *Dendrobium* and *Centaurea*.

GREEN VEGETABLES *versus* THE MILD WINTER.

Many gardeners will be anxious in this advanced season to have all available ground cleared of winter crops, and dug preparatory for spring planting and sowing. A word of caution is called for to prevent any undue haste in making away with anything of the Brassica tribe that may yet prove useful. We are a long way off a good cutting of that delicious esculent Asparagus in quantity, or of Cauliflower, and spring Cabbage will most likely bolt in many instances. Spinach seems the only crop likely to be plentiful as a change vegetable. I would then urge on those who possess old Cabbage beds from last spring cuttings to let them remain for the present. Late planted Brussels Sprouts or Kales may yet be useful. The true Buda Kale, also Purple Sprouting Broccoli, raised in May or early June, are often highly serviceable. The early sowings of Cauliflower should be well on the way by this time. It is well to sow a few rows of Spinach now, to relieve and succeed the winter sown. No mistake will be made in forwarding spring-sown Lettuce, and having relays of French Beans and Peas in pots. Any little exertion that is needed to bring about choice early produce is more than counterbalanced by the ease of mind attained thereby.

SUCCESSION OF BROCCOLI.

How frequently do we see whole breadths of these coming in together, to be half wasted. This comes of the common habit of planting too many of the same variety at the same time. The safe plan for obtaining a steady successional supply all through the season is not to depend on two or three varieties, but to have at least six or eight of the most approved. Most seed catalogues class them into four divisions—namely, certain varieties that form heads in autumn, in early winter, early spring, and late spring. Select two for each division. For autumn, Sutton's and Veitch's Autumn Protecting are good, Snow's Winter White and Sutton's Winter Mammoth follow, and so on, until the seasons are provided for. We cannot always rely upon certain varieties coming to time, as in mild winters like the present they come in in advance of their proper season. By sowing the two first divisions in March, the next two in April, and others still later, a long supply is maintained by planting two or three rows, or more, as necessity demands, of each variety in turn on firm ground. Some of the best Broccoli I ever had were put in with a crow bar without the ground being dug. The plants should be 2 feet apart, well watered, blind or dead plants replaced, and a steady succession will be the outcome, instead of a glut at one time or a stint at another.

SEAKALE CULTURE.

The present time is suitable for forming new plantations. Formerly and in isolated instances at the present day the plants are allowed to do duty for years, being forced with fermenting material on the beds. This serves the purpose to a degree, where the plants do not canker. This they do with me after the first year, and therefore I have adopted the yearly planting of thongs, and shall not revert to the older system again. I always use the same ground; the soil is naturally of good depth, being annually trenched to secure the roots intact, as every little piece overlooked will grow. When a sufficient number of crowns have been dug for forcing, the roots are broken off from the main stem, and the strongest of these selected for sets. These are formed in 7-inch lengths, cutting the head square, and the opposite end slantwise, so that there will be no difficulty when planting in determining the right way uppermost. When the ground is cleared, holes are made 18 inches apart, and a set dropped into each, with the crowns an inch under the

surface. The holes are made with a Potato dibber. This leaves a good margin for some fine rich soil, such as potting bench refuse, with which each hole is filled. When growth commences we remove all shoots but one—the strongest. We keep the ground clean by the use of the hoe, and apply a dressing of nitrate of soda about three times during the growing season, and crowns are obtained of the highest merit.

DENDROBIUM SPECIOSUM HILLI.

The short note by "Herefordshire Incumbent" on this variety of *Dendrobium*, in a previous issue, with the attendant difficulty in coaxing, or shall we say starving it into flower, tallies exactly with the treatment meted out to a small specimen of Hill's variety at Lillesden some years ago. Amongst a collection this one absolutely refused to flower until Mr. Channing, the gardener, suggested what might be determined as "a shocking case of neglect." The plant was in a broken pot to commence with, and its destination a shelf in the sunny end of the greenhouse, with a final, "let it take its chance," which it did; once in a way, perhaps, it had a sprinkle from a passing watering-pot, and remained there for some months. I forget exactly how long, but one day towards the latter end of the summer, in glancing at it, I saw several small growths appearing. The plant was taken down, its dusty leaves sponged, the thirsty roots nourished with a dip in the tank, and in the end we were rewarded with five fine spikes of its cream-coloured flowers. I have a photo of it, but it is not suitable for reproduction, and I think it is a variety hardly worth the trouble to grow.

CENTAUREA CANDIDISSIMA.

On page 132, in a previous issue, I referred to these being used here in beds with Box edging a foot high. I am reminded by "H. H. R.," page 176, in his remarks anent the same, that plants grown in such a "shady depth," as my impression seems to suggest, would be unsuitable for cuttings. Undoubtedly, but I should have explained that the beds were raised 9 inches, and the Box edging so thick as to keep the soil in position, hence the plants inside had ample room to develop and grow sturdily. I agree with "H. H. R." that *Coleus Verschaffelti* and the *Centaurea* form a splendid contrast, not to be excelled by any other combination.—GEO. DYKE, *Stubton Hall Gardens*.

CARNATIONS IN THE MIDLANDS.

YOU have doubtless received ere now from your estimable Birmingham correspondent a report of the beautiful show of spring flowers held in the Botanic Gardens at Edgbaston recently. It was when down there for a day just to see and assist at this show I was favoured with a look over Mr. Robert Sydenham's collection of Carnations, which he grows so admirably in his garden at his Bristol Road residence. I found the entire collection of several thousands of plants just getting established in their flowering (10-inch) pots, and were all in light airy span frames or in cool houses. What must be seen in the matter of bloom and beauty in July it is not difficult to forecast; but finer evidence of the value of the Carnation as a town plant—and Birmingham is indeed a smoky city—could not very well have been furnished.

The Bristol Road garden is hardly a mile and a half from the centre of the great hardware borough, yet the Carnations seem to revel in the smoky atmosphere. Perhaps they rather like the sooty compound after all. The plants were all potted in fours, and all from the previous year's layers. There was not about them the least vestige of maggot or fungus. They were full of health and vigour without displaying any undue coarseness. The effort of the grower just now is to keep them as cool as possible by furnishing an abundance of air.

Mr. Sydenham, in a little treatise on "Carnation Culture," published in the Midland Carnation Society's schedule, mentions that he gets his chief factor (yellow turfy loam) from Kettering. I saw this, and noted that it was of a medium texture, full of fibre, and was undoubtedly good. This loam constitutes about one-half the final compost, as to it is added in limited quantities old leaf mould, burnt ash, and sea sand, he having a high opinion of the value of salt; good old well-decayed stable dung, or spent hotbed manure; and a little sifted old mortar refuse, an ingredient that is most useful for many plants that have alpine origin. This is a compound that anyone who can first obtain the turfy loam can mix for themselves. Then with respect to drainage, he mixes with the broken potsherds pieces of charcoal, crushed bones, and bits of mortar. The mortar, bones, and a little soot all have the credit of rendering the flowers brighter and the colours purer. The potting should always be done before the roots in the small pots become hard or bound.

The soil need not be too hard pressed, as it will settle down firmly through frequent watering, and a small top-dressing may be given later as desired. Of course very much more may be said, but I infer from what I know and have heard and read, that given good varieties, good compost, fair surroundings, and some material attention Carnation culture for exhibition is not at all difficult, or such as should deter anyone who loves the flower from embarking in it. With love of course must be some enthusiasm, and that feature is becoming very marked in the Midlands. Mr. Sydenham has no nursery, or one rod of ground anywhere, except what he has at Edgbaston, and this is a veritable amateur's garden, and no more. Without doubt men of his temperament, whether professional or amateur, can do great things in the interest of horticulture, and they do. It would be easy to enumerate scores of men of both descriptions who have accomplished much. All honour to them.—A. D.

WEATHER IN LONDON.—The days have been calm, dry, and cold of late, except during sunny intervals. Sharp frosts have occurred on several mornings, the thermometer on the grass registering 20°, or 12° of frost. Cold drizzling rain fell on Wednesday.

— WEATHER IN THE NORTH. — Following an extraordinary display of aurora borealis, on the evening of the 15th inst., three days were dull and drizzly, with a high westerly wind throughout the night of the 17th and the following day. The 19th was a fine bright day, with a coldish northerly wind. There were 5° frost on Sunday morning, and 2° on Monday, but both days were beautifully sunny and springlike, and, with a mere touch of frost, Tuesday also promised to be fine.—B. D., *S. Perthshire*.

— THE R.H.S. AND AFFILIATED SOCIETIES.—A wish having been expressed by some of the societies which are affiliated to the Royal Horticultural Society that they may be allowed to use the Society's badge, the Council desiring to meet this very legitimate wish for some outward symbol of affiliation, but considering it better that the badge should not be actually identical with that in ordinary use by the parent Society, have caused a new badge to be struck, which may be used by affiliated societies, on letter paper, schedules, &c., as they may think fit. A printing block of this badge will be presented to every affiliated society (now numbering over 100) on application to the Secretary, and on signing an undertaking to return the same if the affiliation should for any reason be ended.

— FORSYTHIA SUSPENS. — Few hardy shrubs make a finer display at any time than this plant, and flowering as it does in March makes it indispensable where a display of flowers is wanted at that time. It is one of the best natured shrubs we have, as it will grow and flower freely where many other plants would refuse to grow. Possibly it is seen to its best advantage when grown in close proximity to a group of evergreens, though it is difficult to imagine a place where it would be undesirable. When grown in a bed it is a good plan to prune rather hard after flowering, removing weak growth, and shortening strong to a few eyes. By this means shoots 6 to 8 feet in length are made during the summer, which produce flowers from every node the following spring. Plants which have assumed a semi-wild state are better left unpruned, or but slightly thinned.—W. D.

— SPRING GARDENING AT HAMPTON COURT.—Ample evidence is now to be seen of the way in which the new garden superintendent of these gardens is up to date in respect of making them attractive to the masses who visit them. In previous years a block of beds fronting the Palace chiefly have been filled with spring flowers, and these were almost exclusively Polyanthus of a not too varied nature, and Tulips not too robust. This year, for the first time, visitors see every bed in the long line, which borders the great gravel parade or terrace, filled with bulbs, including Hyacinths, now showing fine and promising spikes of bloom; and top or surfacing plants in good variety. There are the Polyanthus still, but not so monotonously planted; and some of them show rich colours and fine form. Another year it is hoped that the weak whites and yellows will be discarded, and only the best employed, and separately. The greater use of deep colours cannot be too highly commended. Then there are double red and white Daisies, Violas and Pansies in colours, Arabis, Wallflowers, *Myosotis sylvatica*, *Silene pendula*, Anemones, *Doronicums*, and similar plants. Some of these will probably bloom rather late, perhaps for a spring display too late, but they will at least furnish bright masses of colour, which will be far more pleasing than bare beds. All the old herbaceous beds have been thoroughly renovated and replanted, and so too has the long border that margins the Palace side of the terrace, and its planting in good clumps rather than in long formal lines should prove to be most attractive. This border sadly needs for its great length material widening. On these beds and borders labelling is not at all a picturesque feature, as an army of wood labels setting up 10 inches out of the ground makes each bed or border to resemble a miniature cemetery. Perhaps the Commissioner of Works may presently furnish something equally useful and less offensive. Many of the inner section of beds have been turfed over, a gratifying proceeding.—A. D.

— GARDENING APPOINTMENT.—Mr. T. Collings, for four years foreman at Swallowfield Park, has been appointed gardener to Fairfax Wade, Esq., Holme Park, Twyford, Berkshire.

— ALMOND BLOOM.—The Almond trees are just coming into blossom. I do not think they are any earlier than usual, though it has been asserted that in Battersea Park they are a month before their time. The retarding weather influences since March came in have served to prevent the blooms fully opening, but the first genial day of sunshine brings them out at once.—E. D. S., *Gravesend*.

— PRUNING FILBERTS AND COB NUTS.—A few days ago my employer remarked to me, "Is there any special way of pruning Nuts?" I detailed my mode of practice, which I have always carried out on similar lines to those advocated on page 226. I have usually had fair success by doing so, but judge of my surprise when my employer informed me of a well known firm in Devonshire sending all the way to the county of Kent for men expressly to prune their Nuts, as they found it rather difficult to obtain competent men in the former county to carry out the operation. If there is a better way than the one detailed on page 226, I, for one, and I have no doubt other readers of the Journal, would like to know. Perhaps some of our Kentish brethren would give us a few wrinkles on the subject.—G. HAGON, *Fowley*.

— CARNATION MARGUERITE.—From a single packet of seeds useful plants of these charming Carnations may be raised, and are very suitable when grown in pots for conservatory and other decoration. In order to insure their flowering the same season, February and March are the times to sow. Shallow pans are the best receptacles for the seeds, and a warm house is a suitable position. Remove the seedlings when large enough to small pots, and increase as required to 5 and 6-inch. A bed of cool ashes in a frame is a good place to stand the plants during the summer, and with due care in watering and attention no difficulty may be experienced in growing graceful specimens, either suitable for decoration or giving a supply of blooms for cutting. The colours vary considerably, and invariably some of the plants only produce small single flowers, which should be weeded out as soon as they appear. Late sown plants do not often attain sufficient size to bloom well the same season.—H.

— CAMELLIA RETICULATA.—Although not grown to anything like the extent that *C. japonica* and its varieties are, this species is held in high esteem in those establishments where large plants are to be found. In general appearance it differs from *C. japonica* by its looser habit, longer, more acuminate leaves, and larger flowers. The form usually met with has large, semi-double flowers, which are bright rose in colour. The petals are broad, about 2 inches long, fleshy, and undulated. The centre of the flower is made up of a mass of bright yellow stamens which are about 1 inch in length. When fully expanded the whole flower bears some resemblance to a semi-double form of the Tree Pæony. This form was known about twenty years before the single-flowered typical plant was discovered, the type being found by Capt. Champion in the woods in Hong Kong. See "Bot. Reg." t. 1078. The plant described above was figured in the "Bot. Mag.," t. 2784, as long ago as 1827, the figure being made from a plant imported by Captain Rawes, and flowered in the collection of Thos. Carey Palmer, Esq., at Bromley, Kent. At present a large bush may be seen in full flower in the winter garden at Kew.—D. K.

— SULPHUR AND RED SPIDER ON VINES.—In response to Mr. Craven's suggestion, I have to say that the sulphur I so invariably found effective in destroying red spider was invoiced to me by a drysalter, who supplied it to woollen manufacturers under the name of "sublimed sulphur." It looks quite different to any I ever got from nurserymen and grocers, being finer and less flakey looking; and its effects were more distinct even than its appearance. I believe it is obtained from iron pyrites, by a process described in "Miller's Inorganic Chemistry," second edition. I recommended this sulphur some years since to my old pupil and friend, Mr. Fisher of Stackpole Court Gardens, and his grocer sent direct, I think, to Huddersfield for it, and Mr. Fisher expressed himself quite satisfied with the result of its application. The pipes should be well loaded with it in a dry state. There need be no fear of applying a strong heat. It is quite safe up to 400°, a heat you can never get in hot-water pipes. The fear of any injury from a dry night air for ten days need not disconcert anyone. I never saw the least injury to berry or leaf from it, provided the Grapes were about the stoning point before applying it, and the sulphur was thoroughly cleaned off the pipes before firing began next season.—D. THOMSON.

— **DOUBLE PRIMROSES.**—Double Primroses are not readily propagated from seed, because the truest double flowers have attained to this condition owing to the essential organs of the flowers having lost their natural functions by becoming transformed to petals or floral leaves.—E.

— **NITROGENOUS MANURES.**—The chief use of nitrogenous manures is to promote growth, therefore all kitchen garden crops upon which we depend for a supply of luxuriant leaves, hearts, or stems are benefited by manuring reasonably with nitrogenous food, as, for instance, Asparagus, Celery, Cabbage, Cauliflowers, Brussels Sprouts, Rhubarb, Savoy, Spinach.—E. D. S.

— **WOLVERHAMPTON HORTICULTURAL CLUB.**—At the monthly meeting of the members of this Club, held on March 1st, Mr. Burrows, Berwick House Gardens, Shrewsbury, gave an excellent paper upon "The Cultivation of the Dendrobium." The subject was treated in a very able manner, and some photos of houses full of Orchids grown by the essayist showed clearly that he is a skilful cultivator of this beautiful and interesting class of plants. There was an excellent attendance of members, who showed their appreciation of the paper by the hearty discussion which followed.—J. F. SIMPSON, *Chairman*.

— **TRITOMA SAUNDERSI.**—This beautiful Torch Lily is not easily grown everywhere, and the treatment indicated by "N. N.," on page 242, may help some who have up till now failed with it. It may be well to point out that there is a possibility of erring on the side of keeping the plants too dry in summer. Even in wet districts some growers find it worth while to dig a trench round their plants, and to fill it nearly up with well-decayed manure. In summer several canfuls of water are frequently poured round the plants. This often vastly increases the beauty of the Kniphofias.—A. HARDIMAN.

— **RIBES SPECIOSUM.**—This Californian species is the most conspicuous of the spiny section when in flower. The flowers are pendulous, deep red, 1 to 1½ inch in length, with long protruding stamens, the whole bearing some resemblance to the smaller-flowered species of Fuchsia. When not in flower it can be readily distinguished from the other spiny species by its upright habit, bright brown bark, and by the wood (particularly when young) being densely clothed with stiff hairs and spines, which are the same colour as the bark. Although quite hardy, it flowers better if it can be accommodated with a position against a wall. When grown in such a position the flowers are produced during March; in the open ground flowering takes place several weeks later.—W. D.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the meeting of this Society held on Wednesday evening, the 16th inst., at the Institution of Civil Engineers, Mr. F. C. Bayard, L.L.M., President, in the chair, a lecture on "Photographing Meteorological Phenomena" was delivered by Mr. A. W. Clayden, M.A., Principal of the New College at Exeter, who gave details of his experience as Secretary of a Committee of the British Association. After referring to the extreme value of photographic methods of recording the movements of instruments, the lecturer spoke of the real importance of preserving photographic records of all sorts of unusual meteorological phenomena, and emphasised the necessity of companion photographs showing the same scene under normal conditions. It was suggested that meteorologists throughout the country should co-operate with the Royal Meteorological Society in securing such records. The phenomena of the lightning discharge as distinguished from those of a single flash were next described and illustrated by a number of lantern slides. Some of the puzzles offered by lightning photographs were next alluded to, and the lecturer stated that he had repeatedly found that a single discharge lasted several seconds. Mr. Clayden then spoke of the "black" flashes shown in photographs, and described the steps by which some years ago he was led to the proof that they were merely a photographic phenomenon, but one which still remains unexplained. Passing on to a consideration of cloud photography, the various methods in use were explained, and a large number of lantern slides were exhibited, in some of which the clouds were shown on a background of blue sky in nearly their natural colours, a result obtained by the employment of suitable developers on a specially prepared plate. The method employed at Exeter by the lecturer for the measurement of cloud altitudes was fully described. This differs from all other methods in using the sun as a reference point. Mr. Clayden then spoke of the difficulty in getting good pictures of cirrus clouds, and described the methods dependant on the polarisation of the blue light of the sky, but expressed a conviction that polarisation had nothing to do with their efficiency, which was really due to a general lessening of brightness which enabled the exposure to be properly judged.

— **SOOT.**—Soot, as a rule, when employed as a fertiliser, is best used alone, but to destroy slugs lime may be mixed with it. The latter is rather the more wasteful plan as regards the fertilising qualities of the soot, lime quickly liberating the ammonia, which may be lost.—D.

— **VICTORIA NURSERIES, WEST HUMBERSTONE.**—Mr. H. Dunkin, for nearly seven years gardener to the Earl of Warwick, The Castle Gardens, Warwick, has taken the Victoria Nurseries, West Humberstone, Leicester, and enters into possession on the 25th of March.

— **THE HESSLE GARDENERS' SOCIETY.**—A meeting of the above Society was held in the Parish Hall on Tuesday, March 15th, Mr. Geo. Picker (Hesslewood) in the chair, when Mr. McIntosh, County Asylum Gardens, York, read a scientific and interesting paper entitled "The Laws of Nature Relating to Horticulture." The essayist described the different constituents necessary to plant life, and the manner in which they were taken up. He spoke of the influence frost and sunshine had upon vegetation, and also gave recipes for one or two excellent manures. Owing to the inclemency of the weather there was a poor attendance.—G. W. G.

— **AKEBIA QUINATA.**—In favoured localities this climber will stand uninjured through ordinary winters in the open air, but when it can be accommodated in a cool house with a pillar or similar support to ramble over, it is seen to much better advantage. When grown inside it flowers during March. The flowers are produced in short drooping racemes from almost every node of the previous year's growth. The flowers are purple in colour. It is a native of China and Japan. As it can be readily grown from cuttings, either of stem or root, grows very quickly, and flowers freely, it is worthy of note either for a cool house or sheltered place outside.—D.

— **FRUIT FROM THE CAPE.**—A second cargo of fruit has recently arrived from the Cape. The ss. "Norman" of the Union Line brought 242 boxes of Nectarines in first-class condition, which realised good prices; 62 boxes of freestone Peaches, also sold at good prices; 417 boxes of clingstone Peaches which, for the description of fruit, realised fair prices; these latter are not considered a good sale in this market. Some 30 boxes of black Grapes, which were very small and of poor quality, were sold at only nominal prices. Pears were sent to the amount of 40 boxes, which arrived in good condition, and fair prices were realised for this, the first consignment of the season.

— **SPRING TRENCHING AND RESULTS.**—I am sending you an Onion, as a sample, grown on the boys' gardens at Hawkhurst. It is Ailsa Craig, and the weight when lifted was just over a pound. There were (and are) many more like it. The important point in connection with the bulbs is that they are not the produce of box sowings, but resulted from seed sown out of doors early in April last year. The ground is stiff, wet clay. Up to the middle of March, 1897, it was under turf. I had the latter removed and the ground trenched in the wet spring of that year. We not only had some grand Onions, but a splendid lot of Peas and other vegetables. At the local shows the Onions were an easy first. Some people are asking what the boys will do when they get to be men if they go on like this. If you allude to this in the Journal do not forget to notice that the fine Onions and other vegetables were the result of spring work, not autumn or winter trenching, as the fact is suggestive, and should, I think, please Mr. David Thomson. He is a grand old man.—INSTRUCTOR. [The Onion is a model, finely shouldered and 14 inches in circumference. We have not seen a finer from autumn sowing in April.]

— **KERRIA JAPONICA.**—The double form of this Chinese shrub is frequently met with in gardens; the type, however, is not very often seen. Both are desirable garden plants, being easily grown, if given fairly good soil, in almost any position, and producing their deep yellow blossoms in great profusion every spring. The double form was in cultivation for a considerable period in this country before the typical plant was discovered. The single variety is not so vigorous as the double, but is more graceful in habit. The flowers are about 1 inch across, and produced on almost the whole of the previous year's growth. If left to itself it makes a dense bush 3 to 4 feet high. To be seen at its best a quantity of the old wood should be thinned out every year after flowering; by doing this long young shoots can be obtained, which produce abundance of blossoms. Plants lifted, put in pots in autumn and slightly forced, come in very handy for decorative work in spring. In addition to the double form there is a useful variety with silvery variegated foliage; this also flowers freely. Anyone who has a single plant of either can quickly raise a stock, as cuttings root readily in sandy soil in a cold frame during summer, and young plants grow quickly.—D.

— **MANURING MINT.**—In reply to "H. S.," page 239, I have not found Mint beds decline from a judicious top-dressing of decayed manure, but I have noticed the attack of fungus he speaks of in the old, impoverished portion of beds, also in plots where the Mint was planted in dry, poor situations. The reason of the fungus is not so much the manure, but the natural result of the decomposition of the old, exhausted underground rhizomes. The most luxurious and healthy Mint is found on the outside of old beds or newly formed breadths. The best treatment is to replant by inserting cuttings in the early part of May.—E. D. S.

— **TRANSACTIONS OF THE SCOTTISH HORTICULTURAL ASSOCIATION.**—The twenty-first annual report, embodied in the "Transactions" of the Society, is to hand, and is written throughout in a congratulatory tone. Everything is in a sound state, and the Society by its meetings must be doing good service to horticulture in Scotland. The papers that have been read during 1897 are given in abridged form, and contain much practical information on widely divergent gardening subjects. The arrangements for this year comprise many subjects of considerable interest to horticulturists. Mr. R. Laird, 17, South Frederick Street, Edinburgh, is the esteemed Secretary.

— **MAGNOLIAS IN POTS.**—These showy spring-flowering shrubs are admittedly beautiful objects for covering walls in sunny positions; but how often it happens that their beauty is destroyed in a single night by a sharp frost or heavy driving rain. Still I do not want to depreciate their great value on that account, being rather to plead for their extended culture in pots. At Barford Hill, near Warwick, I recently saw some very fine specimens in pots flowering grandly. Mr. R. Jones considers them to rank among the best of hardy shrubs for pot work, and in the future intends to grow them largely in that way, as they supply splendid objects for conservatory decoration, as well for handsome cut flowers. The varieties I noticed were *conspicua*, *purpurea*, and *purpurea Lenné*.—TRAVELLER.

— **HEBECLINIUM (EUPATORIUM) IANTHINUM.**—This fine member of a valuable winter-blooming family of plants was the other day carrying very fine panicles or trusses of lavender blue fluffy flowers at the Edgbaston Botanic Gardens. The numerous good strong plants carrying blooms made it a very striking feature. This strong-growing variety is much more effective than are the pale-hued, small-leaved varieties so commonly met with. It makes a capital companion plant to cut-back *Clerodendron fallax*. The variety named *H. ianthinum*, though classed as a stove plant, evidently likes a medium temperature best, as is evidenced at Birmingham. Those gardeners who may want something striking for conservatory decoration in the early spring should get a stock of this fine *Eupatorium*.—A. D.

NARCISSUS MINIMUS.

I AM obliged to Mr. Divers for his interesting note on page 167. I should be glad to see more of the same kind from him and other growers of hardy flowers. The first flower of *N. minimus* was on a clump on one of the lower terraces of a rockery, with an exposure almost due south, and "protected from the north by a greenhouse about 7 feet off, and from the east by the house, which is about 10 feet from it. It is fully exposed to other directions, and is in light dry soil. Our climate in the west of Scotland is, however, considerably milder than is imagined, and a Ross-shire correspondent told me a fortnight ago that he had *Gladioli* of the *Ramosus* section 2 feet above the surface of the soil. I have not kept my garden book of plants coming into flower very regularly for some time, but I see that in 1890 *N. minimus* flowered on 13th January; in 1891 on 28th February; in 1892 on 8th February. It was not in the same position then, but had more shelter, and a little less sun in winter. It may interest Mr. Divers to know that the first blooms of *N. pallidus præcox* and the *Saragossa* Daffodil opened on 10th February. The only other record I have of *N. pallidus præcox* is in 1892, when it opened the same day as *N. minor*—viz., 19th March. Much depends upon the situation, and unless the plants remain in the same situation for several years a record of dates is perhaps more interesting than valuable.

As a general rule, I find that bulbs lifted and dried come into flower earlier; but here again situation and also weather conditions come into play, which greatly modify the rate of progress. Times of lifting and planting are important factors, and it is quite possible that the unlifted *Narcissi* at Belvoir may have made some growth before the others were planted, and that the weather conditions were such as to prevent the latter from making growth for some days. My remark was founded upon a good deal of experience with bulbs of various kinds. Within certain limits I find that bulbs, especially those newly from the Continent and Asia Minor, which have been dried come earlier into growth and flower than those established for several years. This refers not only to *Narcissi* but to *Snowdrops*, *Muscari*, *Erythroniums*, and a number of others. These often come into growth too soon for their comfort, and to this I attribute many of the losses I have had.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

EXHIBITING HARDY HERBACEOUS FLOWERS.

YOUR correspondent, "N. N." (page 243), has done good service in again ventilating this subject. It is to be hoped that the managers of flower shows may eventually see their way to adopt the regulations of the R.H.S. Judging Code referred to in your note, in which the maximum size of the tube is given.

The size of many of the bunches now exhibited is sufficient to defeat the object of the competitions, which is, one would suppose, the encouragement of the growth of flowers for which the prizes are offered. In many of these bunches there is no attempt to show either the habit of the plant or even what is usually required in what are known as florists' flowers, the points of merit of the individual blooms, spikes, or trusses. The great object in the eyes of some exhibitors appears to be to secure great masses of colour to attract the eye. Too often these tactics meet with the approbation of the judges, and stands more meritorious, because of more tasteful arrangement, better grown flowers, and greater rarity, are passed over. I believe that nurserymen who show the enormous bunches spoken of will in the end find it to their advantage to reduce their size and exhibit more of the little-known plants. As things are, frequenters of flower shows who have little opportunity of visiting other gardens than their own, can form no idea of the stateliness or grace, as it may be, of the flowers they see shown. A suggestion which has been thrown out of showing some herbaceous flowers in pots is worthy of commendation, but, I fear, involves an amount of work and expense which few would be disposed to undertake.

Those interested in the subject should send 1s. 1d. to the R.H.S. office, 117, Victoria Street, S.W., for a copy of the Judging Code, which is of the greatest value to schedule makers as well as judges and exhibitors.—S. ARNOTT.

NOTES ON ALPINE FLOWERS.

(Continued from page 192.)

ARENARIA BALEARICA.

THERE are some very pretty plants among the Sandworts, and although some have larger flowers, none give more pleasure to the grower of alpinists than the one under notice. It forms a mass of growth scarcely rising above the stones to which it loves to cling. It is almost moss-like in its appearance when out of flower, but when it begins to bloom the Balearic Sandwort is freely spangled over with tiny white flowers raised a little above the small green leaves. *Arenaria balearica* likes a rather moist place, and in such will soon creep over and cover a boulder of sandstone or other porous rock. It is quite hardy, but if not freely exposed to the light is liable to be lost.

The writer has never seen it grow so well as on the stones in front of a hardy fernery, which had a glass covering overhead, but was open in front. For the benefit of the Ferns the hose pipe was freely applied, and the Balearic Sandwort seemed to revel in the moisture and protection. It covered the stones and rambed in and out among them in the most pleasing way. On old walls where fairly moist it often looks very beautiful. The native habitat of *A. balearica* is correctly indicated by the specific name of the plant—which is not an invariable rule with plants bearing the names of places—as it is a native of the Balearic Isles. *A. balearica* is readily increased by division, but those who wish to secure its establishment in their rock gardens would do well to obtain their young plants in pots, as they would become established sooner than if sent without a ball of earth attached.

EPIMEDIUM MUSSCHIANUM.

While Mussehe's Barrenwort is not the best of a somewhat neglected genus, it is a pretty little plant which generally receives some praise from garden visitors if its somewhat small flowers are brought under their observation. It is of dwarf habit, and the flowers are not pure, but rather dull white in colour. Not many flowers are produced on the stalks, and the biternate leaves are composed of nine leaflets, of what are called cordate-ovate form. It is of dwarf habit, and grows only from 6 to 9 inches in height as a rule, although soil, moisture, and position modify its height to a considerable extent. Like others of the genus, *E. Musschianum* is propagated by division after flowering. This *Epimedium* likes a peaty soil, and thrives well in shade, although it grows very satisfactorily in the open. A native of Japan, it was introduced in 1836.

SAXIFRAGA BRYOIDES.

To plant authorities on the genus this Rockfoil is known as *Saxifraga aspera* var. *bryoides*, but for garden purposes the abbreviated name which appears above is amply sufficient. Although the growth is somewhat similar to what is known as the typical *S. aspera*, *S. bryoides* is distinct enough in general appearance to be readily recognised. *S. aspera* is much rougher and greyer-looking, and *S. bryoides* is much brighter green, and in certain stages of growth is extremely beautiful through the verdancy of its foliage and the peculiarly pretty way in which it grows, making its branches resemble green velvet cords, if such can be imagined. Like *S. aspera* it is, however, a very shy bloomer. It belongs to the mossy section, and is increased by division. *S. bryoides* is a native of Europe, and prefers a rather moist position.—ALPINUS.

(To be continued.)

THE SCIENCE AND PRACTICE OF FORMING FRUIT TREES.

RESULTS OF PRUNING.

ON page 207 (March 10th) was shown the method of pruning by which the long and strong shoots are shortened, the short and weak retained. The results of such practice I now endeavour to depict and describe.

The shortening was moderate. The topmost buds push the more strongly, as shown at J (fig. 55), and the others in degrees of vigour downwards to the base, most, if not all the buds starting. This is a matter of consequence, as the shoots (*u*) are required for forming permanent branches, and the side growths (*v*) for spurs to yield fruit. (See the figure first referred to, March 10th). The short shoots also produce some growths, but more particularly a number of leaves, which aid in the elaboration and storing of nutrient matter. The young extensions are not hampered by these growths, but receive a full measure of light and air, so that they become sturdy and well matured (*w*, in the present illustration), and even the shoots below them are in good trim (*x*),

The principles apply to the pyramid (*L*), this only requiring the shoots shortened in July, if growing too freely, and keeping the growths sufficiently far apart to permit the sun to shine in between the branches. The shoots can be shortened in the spring as may be desired for forming additional branches; or when ample and not unevenly balanced, leaving the extensions intact. Shortening, however, will mostly be required in the early years after planting, but too much shortening is a very common error, as resulting in useless annual wood growth instead of the production of natural spurs and fruit.

The result of hard pruning all the shoots (page 246, March 17th), is shown in the tree *M*. Each strong shoot cut hard back has started every bud, and a number of shoots (*N*) is the consequence, the longest at the top and shortest at the base. The extremity shoots (*b*) take and maintain the lead, whilst the others cut back to one bud have pushed relatively strong growths (*c*). Thus, in the autumn, there are a number of shoots (*d*) that are not required, and must be cut back to a couple of buds, unless this has been attended to in July by pinching them to the third leaf, and subsequently. If left, there is no reason why they

FIG. 55.—RESULTS OF PRUNING YOUNG TREES.

References.—Tree *I*—Strong shoots shortened and weak retained (page 207); results (above)—*w*, leafless strong shoots showing points of shortening; *x*, leafless short growths; *y*, spur in fruit. *J*, shortened shoot, showing rate of pushed growths. *K*, leafless shortened shoot with pruning marks; *z*, spurs; *a*, root formation. *L*, pyramid part in leaf and part leafless, indicating shortening. Tree *M*—the result of all shoots cut back; *b*, extension shoots in leaf; *c*, growths from cut back short shoots; *d*, the same, leafless, marked for pruning; *e*, leafless extensions marked for shortening. *N*, growths from cut hard-back shoot, showing starting of buds to the base. *O*, leafless shoots after cutting hard back with mark for pruning; *e1*, root formation.

so that they may, if considered advisable, be left as may be needed for furnishing the tree. They have, however, done what was mainly required of them—namely, the speedy re-establishment of the tree, and may therefore be partly or wholly cut away. This thinning and shortening is best done in the summer, say about the middle of July. It can, however, be left undone until the tree is leafless, then operating as shown in the leafless branch (*K*), always leaving the short stubby shoots or spurs (*z*) intact. The shortening of the extensions, as indicated by the bars in *K*, can be deferred until spring, so that we get more roots than top growth, and this of a very fibrous character (*a*).

In the way described the tree can be treated year after year until as many branches are had as desired, always keeping those of berry fruits at least 9 inches asunder, and those of Apple, Pear, and stone fruits between 1 and 2 feet. There must be no crossed branches to prevent the sun shining right into the centre, as we wish to secure a large fruit-bearing area, and to have the fruit even in size and colour. Nothing could possibly be simpler than the formation of the bush or standard tree on the lines suggested, which is that of the modern system of fruit growing, as distinguished from the cut-into-form method, regardless of the production of fruit.

should not be cut away in the early autumn, and then the movements of the juices will be free to act on the extensions. One result of the “cut-all-shoots-back” method is that a certain break is secured if there be sufficient vigour in the tree, every bud starting from the pruning bud of the shoot down to the base as shown at *O*. The tree thus made to produce wood has correspondingly fewer, but stronger roots, the generality being relatively long, and according with the character of the shoots.

The close pruning will not give strong and long shoots on a hard soil, for the roots will then be much branched or fibrous in proportion to the resistance encountered. Such trifles upset all the calculations of the physiologist, and the hard-pruned tree may produce short-jointed wood and plenty of fine fruit, whilst another tree in a looser and richer medium, pruned in exactly the same way, produces nothing but wood and leaves, the whole difference being in the soil staple. Still, soil conditions being the same, moderate shortening and some spurs mean a fair proportion of extension roots with an equally due measure of fibres, whilst close pruning implies a larger number of extension roots than the fibres, as indicated at *e1*.—G. ABBEY.

(To be continued.)

NATIONAL CHRYSANTHEMUM SOCIETY.

THERE was a good attendance at the adjourned annual meeting of the above Society, which, in compliance with a motion passed on February 28th, was held at Anderton's Hotel, Fleet Street, E.C., on Tuesday last, the 21st inst., at 6 P.M. Mr. T. W. Sanders presided. As was confidently expected on all hands, the meeting proved a most stormy one, and Mr. Sanders found his office of Chairman anything but a sinecure. The feeling of unrest first made itself felt when before the ordinary business commenced Mr. B. Wynne rose to make some remarks concerning the statement made by Mr. Geo. Gordon with reference to the medals voted by the Society to several of its officers. He (Mr. Wynne) had been a recipient of one of these medals. He had no idea that at the time it was granted that the Society was not perfectly solvent, but after what Mr. Gordon had said about the Society paying its way before it granted

medals to its officers, he felt that the only thing for him to do was to return the medal, for under the circumstances it had ceased to give him pleasure. In replying Mr. Gordon stated that he was sorry that his remarks had been taken thus. He wished to differentiate between the medals, of which Mr. Wynne's was one, which had been all paid for, and the gold medals and illuminated addresses, costing some £22, which had not at that time been paid for. This, he thought, to be reprehensible extravagance.

Mr. Wynne, amid very general applause, then withdrew his objection.

The minutes of the first annual meeting were next brought up. An alteration in the number of votes by which the report and balance-sheet were thrown out was found necessary, the exact figures being 82 votes for throwing out the amendment by 6 against. The minutes were then passed without further discussion.

Mr. R. Fife then proposed that the meeting be adjourned for twenty-four hours in order to relieve Mr. Sanders of a somewhat difficult office. Mr. Sanders was present in the dual capacity of Chairman of the meeting and Chairman of the Committee whose actions the meeting were assembled to criticise. In replying, Mr. Sanders hoped they had sufficient confidence in his impartiality, and trusted that he would be loyally backed up by the members present in his efforts to keep order. He elected to let matters proceed.

Some further alterations were made in the revised financial statement sent out to the members, and this finally stands as under:—

REVISED FINANCIAL STATEMENT, 1897.

The Chairman formally proposed, and Mr. B. Beckett seconded, that the financial statement be adopted, and a lively discussion then ensued in which the various items came in for a good deal of scrutiny and criticism.

Mr. Cholmeley asked why the auditors' signature was not appended, also if it was not a fact that the year's expenditure had exceeded the receipts by £58 6s., and he likewise questioned the disposition of the reserve fund, which, however, the alterations fully made plain. Mr. Cholmeley concluded by observing that if it were true that the Treasurer had never received or disbursed a shilling of the Society's money it was useless to elect a Treasurer.

In reply to a question respecting the auditors, the Chairman said that the auditors had been asked to examine the revised financial statement, but had refused. They said they were not asked to value the Society's liabilities and assets, and if it had been wished that they should do so the request should have been made on or prior to February 24th. They refused, therefore, to recognise the alterations.

Mr. H. J. Cutbush and Mr. A. E. Stubbs made *viva voce* statements confirming their decision, the latter gentleman saying that the first financial statement was both intelligible and accurate, and that they could not go beyond it.

Mr. R. Dean gave a detailed explanation of the reason why the show expenses (£32 7s. 5d.) for 1897 seemed so high. Prior to 1889, he said, the sums were split up under various heads, such as cartage, labour, and hire of plants, and thus while the sum under the head of "show expenses" seemed small in comparison with late years, the expenditure was in reality greater. Thus in 1891 the total expenses for only three shows were £42 12s. 6d., and in 1889 £53 1s. 10d., also for three shows; whilst the centenary shows in 1890 cost only £69 15s., and the Jubilee show in 1897, five exhibitions in all, £59 15s. These figures were, he averred, eloquent of the improvement made.

Mr. Moorman was very severe upon several items appearing in the financial statement. Granted that things were bad in 1889, there had

surely been time enough to reform since then. The printing and medal accounts were, he thought, much too extravagant, and he would like to see tenders invited for both printing and the making and engraving of the medals. He made out the show expenses to be over £102, for he included the £50 for stamps, telegrams, &c. They had gone to the world, as if they had been a flourishing society, which events had proved they were not. Speaking of the Aquarium, he said that it might suit some, but by no means all, whilst he strongly deprecated the practice of selling the best parts of the floor space to sticks, manures, and other trade articles, and driving the grand blooms of Chrysanthemums into dark corners and galleries. With regard to the £18 odd for the annual dinner expenses, he was sure they ought to invite the members of the horticultural press, but they did not want anybody else there just for the glorification of the Aquarium.

Mr. Dean thought that Mr. Moorman's assertion that the £50 for stamps and telegrams was part of the show expenses a reckless one. The schedule cost 1½d. postage per copy, and 2000 copies were sent out. The postage of medals, per registered post, was a heavy item, whilst they had to pay heavily for certificates and medals sent abroad; none of the latter would go under 1s., and some cost as much as 1s. 6d., 1s. 8d., and 1s. 10d. Then there were the expenses consequent on issuing notices and passes, and of the annual outing. All cut blooms for exhibition were acknowledged on receipt, and cards for naming were also sent if desired. All this cost money, and made a heavy aggregate.

Mr. Cholmeley asked what they proposed to do now that the auditors had refused to append their signature to the financial statement. To this the Chairman replied that that was for the meeting to decide.

Mr. Spicer said that they wanted a balance sheet, but that they had only got a financial statement, and asked if the one they were now discussing had been sent out with the Treasurer's sanction.

Mr. Starling replied that it had. On retiring he asked, after looking at several accounts, if that was all the Society owed. He was told no! Up to that time he did not know of Pollett's and Restall's account. Mr. Starling again asserted that last year their ostensible balance of £10 10s. 8d. was not a balance at all, for they owed other monies. They ought to have a balance in hand of at least £300 or £400, and they had nothing but a paltry £50. Speaking of the reason why the reserve fund had been reduced by £50, he said that the bank would not allow them to draw less than £50 from deposit. This had accordingly been done. £14 15s. 4d. had gone to make up the deficit, and the remaining £2 4s. 8d. had been transferred to the current account of the reserve fund.

In reply to a question by Mr. P. Waterer, as to whether there was any cash in hand wherewith to work, Mr. Dean said that he closed his petty cash account on January 31st. Since then there had been two annual meetings, at a cost of £1 13s. 6d. each, for which he had to pay out of his own pocket. He had received, however, on behalf of the Society £11 1s. 3d. during the present year.

The liabilities which were added to the revised balance sheet came in for merciless handling.

Mr. Willis said it had been stated that the auditors knew not of these, but surely they must have found out about them if they had looked at the bills which bore receipts for money paid on account. Mr. Starling corroborated this very emphatically.

Mr. McKerchar asked the Treasurer why, if he had his doubts as to the accounts, he had not laid his doubts before the auditors or the Committee. If the Society contracted debts in 1897 it ought to pay them off in that year, or the members might expect to hear a good reason why.

Mr. Tagg, in a very amusing speech, said that nobody seemed to attach any importance to the financial statement, and nobody seemed to own it. He would like to know who was the father of it, and what it all meant. After further discussion, in which Messrs. G. Gordon, Mills, Rundle, and Bevan took part, the financial statement was finally carried.

It was elected that the report should be dealt with separately. A statement of estimated receipts and expenditure had been prepared by Mr. Dean. This showed that taking the minimum the Society might expect an income of £1066 11s., whilst the maximum of expenditure would be £1115 1s. 6d., or a balance on the wrong side of £48 10s. 6d. It had been decided, however, to still further reduce the expenses to £1044 3s., thus leaving a balance on the right side of £22 8s. Under this arrangement it is proposed not to hire any plants, and the prize money will be reduced. After an animated discussion, in which Messrs. H. Cannell, sen., Tagg, Weeks, and McKerchar joined, the meeting signified its approval of these estimates.

Passing to the consideration of the report, Mr. Cholmeley drew critical attention to its "high falutin" character. The Society's resources might be as great as ever, but that it was financially sound was largely a matter of opinion. Mr. Wilkins commented upon the incongruity of the report and the financial statement. Mr. Ballantine, on the other hand, expressed his belief that the Society's prestige was as great as ever. Mr. Moorman differed, and held up Birmingham and Edinburgh as being far ahead of them. There was, he said, too much of the one man element in the management of their Society. The only alteration made, however, was the deleting of the paragraph relating to the proposed special class for twelve vases of Chrysanthemums, which has been abandoned, and the belated report reached the harbour of safety at last, after a stormy experience, on the motion of the Chairman, seconded by Mr. B. Beckett.

The election of officers followed. The nomination of Sir Edwin Saunders as President, made by Mr. H. Cannell, sen., and seconded by Mr. Langdon, was carried, adopted *par acclamation*. The same might be said for the vote of thanks to Sir Edwin, moved by Mr. Ballantine and seconded by Mr. Langdon.

Mr. Moorman proposed, and Mr. Rundle seconded, that a paid

Secretary having no vote should be appointed, and the meeting agreed to this with but little demur.

There were two nominations for the General Secretaryship—viz., Mr. R. Dean, proposed by Mr. Cannell, and seconded by Mr. Simpson; and Mr. G. W. Cummins, proposed by Mr. Moorman, and seconded by Mr. Mold. The result was decided by ballot, and after the nominations for Committeemen had been received, these, together with the two candidates for the post of Treasurer—viz., Messrs. Ballantine and G. Gordon, were all submitted to the test.

The result was that Mr. Ballantine was chosen Treasurer, and Mr. R. Dean General Secretary by 63 votes to 43. Mr. Cummins had not canvassed for support, but it was known to some members that if a vacancy occurred he was prepared to fill it if desired. The following gentlemen were elected to serve on the Committee:—Messrs. T. Bevan, G. Langdon, A. Taylor, W. Howe, W. Wells, J. P. Kendall, F. Gilks, T. L. Turk, J. T. Simpson, R. Fife, W. Higgs, A. Outram, and W. Daniels.

Mr. T. W. Sanders was chosen as Chairman, and Mr. P. Waterer as Vice-Chairman for another season.

Mr. D. B. Crane's proposal that Mr. C. Harman Payne be asked to continue the office of Foreign Corresponding Secretary met with unanimous approval.

Mr. R. Dean read a communication from the Executive Committee which urged that Mr. J. R. Starling should (1) be elected an honorary Fellow of the Society; (2) be presented with a letter of thanks, signed by the President; and (3) with a small gold medal, with the length of his service in the Society engraved thereon. Mr. B. Beckett moved, and Mr. Ballantine seconded, that this recommendation should be carried into effect, Mr. Ballantine remarking that the letter ought to be engrossed on vellum. The meeting gave a very hearty assent to the proposal.

Mr. Cholmeley and Mr. Stubbs were appointed auditors.

The new rules which had been drawn up were then submitted for the approval of the members, and after several alterations, including the removal of the Secretary's name from the managing body, and as superintendent of exhibitions, were adopted.

Mr. Moorman proposed that "A sub-committee of five members (exclusive of ex-officio members) be appointed to inquire: (a) What places can be obtained for holding future exhibitions, either by a subsidy as now, or in reliance on the Society's own resources; (b) To closely examine the whole question of minor shows with the object of estimating their advantages and otherwise to the Society; (c) To fully consider the question of selling the floor space, to report the result of their investigations to the General Committee, who are now requested to formulate such recommendations to a general meeting of members to be held on the evening of the first day of the November show, and that no further fixtures be made before that date."

No objection was raised to this proposal. On the motion of Mr. C. H. Payne, seconded by Mr. D. B. Crane, Mr. J. R. Starling and Monsieur E. Calvat were elected honorary Fellows of the Society.

A vote of thanks to the Chairman brought the proceedings to a close as the hands of the clock were fast verging towards the witching midnight hour. The meeting lasted nearly five hours.

HIGHGATE AND DISTRICT CHRYSANTHEMUM SOCIETY.

A COMMITTEE meeting was held on Thursday evening last, when the dates of the Floral Committee meetings for this year was settled—viz., October 31st, November 8th and 14th. The Floral Committee was then elected—viz., Messrs. T. Bevan, J. Brooks, J. Brooks, jun., F. Burt, Mathews, and Turk, with the President, the Treasurer (Mr. J. McKerchar), and the Secretary (Mr. W. E. Boyce), as ex-officio members.

BATLEY CHRYSANTHEMUM AND PAXTON SOCIETY.

ON Tuesday, the 15th inst., the annual dinner of the above Society was held. It was presided over by G. Hollis, Esq., who was supported by Mr. J. Farrar, a former President of the Society, J. Bentley, Esq., President of the Morley Paxton Society, Mr. W. Boston, Mr. Western, Mr. Thos. Garnett, Wakefield, and upwards of fifty members of the Society. Delegates were also present from the Bradford, Bristol, Morley, and Wakefield Paxton Societies.

The President, in responding to the toast of "The Batley Chrysanthemum and Paxton Society," proposed by the President of the Morley Society, said that, owing to another important meeting, many influential and warm supporters of the Society were unavoidably absent. He was glad, however, to see present almost every member of the Committee, to whom the public of Batley and district were more indebted than they probably knew for the grand Chrysanthemum show which had been held in the large Drill Hall every November for so many years. Of course he knew and took into account the subscription list, which enabled them to offer so many liberal prizes in addition to the seven valuable challenge cups, which had done so much in stimulating the local growers to a high degree of excellence in their exhibits. In addition to that, their 25-guinea challenge cup, open to all England, had brought to Batley exhibitors of the first rank from far and near, thus lifting their show to a very high level. Owing to bad weather on the show day their balance had fallen a few pounds on the wrong side, but the enthusiasm of the Committee in subscribing the money out of their own pockets—working men as most of them were—had put matters right. They had no reasons for despondency, and he had confidence in a bright future for the Chrysanthemum show, and in other work in which they were engaged.

The other toasts on the list brought out some capital speeches of a business-like and encouraging character, and the enjoyment of the evening was greatly enhanced by a musical programme of patriotic and humorous songs.—T. G. W.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—MARCH 22ND.

THOUGH the day was murky without, and some of the fog penetrated the Hall, yet the brightness of the long tables of flowers predominated. Very brilliant indeed was an imposing display of Hippeastrums, raised and exhibited by Captain Holford, Westonbirt (Mr. A. Chapman, gardener)—an extensive and fine assortment, in greatly varied colours.

Messrs. James Veitch & Sons arranged one of the finest groups of Clivias yet seen—massive trusses of brilliant flowers, being effectively set off by rich green leaves.

Messrs. Hill & Son, Edmonton, exhibited a great and varied collection of Ferns, and Messrs. J. Laing & Sons arranged a diversified assortment of stove and greenhouse plants, also a pleasing assortment of floral decorations.

A fine mass of Narcissi in pots and many cut bunches, also various other hardy spring flowers, were exhibited by Mr. T. S. Ware, and Mr. R. G. Cuthbert, Highgate, arranged a very fine collection of Tulips in pots, Ophir d'Or, a beautiful yellow, showing conspicuously. The St. George's Nursery Company, Hanwell, exhibited a large assortment of admirably grown Cyclamens. Messrs. Cutbush & Sons arranged a bold miscellaneous group, in which the yellow Calla Elliotiana contrasted effectively with the pendant scarlet racemes of Thysacanthus rutilans and other flowers.

Messrs. Wm. Paul & Son had three considerable sized groups of Roses in pots, two of them composed of the beautiful and floriferous Enchantress, and the other of about a dozen of their new varieties, including Souvenir d'Eugène Verdier, Sylph, Madame Julius Grolez, President Carnot, Antoine Riviere, and others that will be seen again. The Waltham Cross firm also arranged one of the largest and finest collections of Hyacinths that has been seen for many a day, all the best varieties in cultivation being apparently represented.

Splendid boxes of Roses were set up by Mr. W. Rumsey, yellows, whites, pinks, and crimsons, commanding the attention of visitors. Mr. Mount had also many beautiful blooms, some supported on long stems clothed with rich green leaves. Messrs. J. James & Son covered a great length of table with such grand Cinerarias as could scarcely have been dreamed of a few years ago. Mr. John R. Box, Croydon, had also an excellent display of these flowers, both plants and varieties being of high merit.

Messrs. B. S. Williams & Son exhibited Hippeastrums, Orchids, dense masses of Azalea mollis, Staphylcas, and various other plants. Messrs. Hugh Low & Co. had a compact group of Orchids in the best of condition and in choice variety.

Messrs. Paul & Son, Cheshunt, exhibited chaste and charming masses of various alpine plants that were much admired. Messrs. Barr & Son had a great and varied assortment of Daffodils of apparently all sizes and in all colours in which these popular flowers are represented. Mr. H. B. May arranged an attractive group of Clematises flowering freely in small pots.

FRUIT COMMITTEE.—Present: G. Bunyard, Esq. (in the chair); with Rev. W. Wilks, and Messrs. T. F. Rivers, H. W. Ward, J. Cheal, J. Willard, A. F. Barron, G. Reynolds, G. Norman, J. H. Veitch, W. Poupert, H. Balderson, G. Wythes, W. Bates, A. J. Laing, F. Q. Lane, W. Pope, C. Herrin, A. Dean, and J. Wright.

The duties of the Committee were extremely light on this occasion. Mr. J. Wythes sent from Syon six punnets of Royal Sovereign Strawberries, splendid fruits, firm and well coloured. A cultural commendation was unanimously awarded.

A new "cultivator," in the form of rotatory prongs, worked by hand, was introduced by Mr. Wythes. It is an implement of promise, and was unanimously referred to Chiswick for trial. It is the invention of Mr. G. W. Shailer, Brentford, and resembles a very miniature scarifier, such as is seen on some farms, but with the important difference that the curved prongs in the new "garden cultivator" revolve in either direction at will—that is, they can be drawn or pushed through the ground, and hoist the weeds, if any, on the surface.

VEITCHIAN PRIZES.—Apples.—First, Mr. J. C. Tallack, Livermere Gardens, Bury St. Edmunds, with Lamb Abbey Pearmain. Second, Mr. C. Herrin, Dropmore, with Sturmer Pippin. Pears.—First prize withheld. Second, Captain Carstairs (Mr. C. Ross gardener), Welford Park, with Nec Plus Meuris.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); and Messrs. C. L. Drewery, H. B. May, R. Dean, E. Molyneux, G. Stevens, J. F. McLeod, R. B. Lowe, J. Jennings, C. J. Salter, H. Selfe Leonard, J. Fraser, J. D. Pawle, C. E. Shea, C. E. Pearson, T. W. Sanders, E. T. Cook, E. Beckett, H. Cutbush, O. Thomas, E. Mawley, H. Turner, G. Paul, H. J. Jones, W. Howe, J. Hudson, D. B. Crane, G. Gordon, C. Jeffries, and James Walker.

CERTIFICATES AND AWARDS OF MERIT.

Amaryllis Ideala (Messrs. Jas. Veitch & Sons).—The flowers of this variety are large, heavily marked with crimson-red on a white ground (award of merit).

Amaryllis Clonia (Messrs. Jas. Veitch & Sons).—This is a charming variety with bold white flowers touched with pale green, streaked and margined with warm rose (award of merit).

Amaryllis Sacola (Messrs. Jas. Veitch & Sons).—Flowers large, brick

red, each segment having a broad white band down the centre (award of merit).

Amaryllis Beacon (Captain Holford).—The flowers of this variety are of medium size, and of a deep velvety crimson (award of merit).

Azalea japonica rubra (W. Nicholson, Esq., Basing Park, Alton; gardener, Mr. Smythe).—The small bright red flowers are borne with delightful freedom (award of merit).

Clivia Favourite (Messrs. J. Veitch & Sons).—Flowers produced in great trusses: colour pale salmon, with a soft yellow throat (award of merit).

Clivia Opitine (Messrs. Jas. Veitch & Sons).—A grand variety, with large well-formed trusses of terra-cotta (award of merit).

Dracaena Exquisite (Messrs. Jas. Veitch & Sons).—Plant of good habit, with broad bronze-green leaves, deeply margined with rosy pink (award of merit).

Hyacinth City of Haarlem (Messrs. W. Paul & Son).—The beautiful primrose yellow flowers are borne on long stout spikes.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien (Secretary), de Barri Crawshaw, Ballantine, Whittle, Gabriel, Chapman, Thorne, Young, Bond, Law-Schofield, Ashworth, Protheroe, Courtauld, Hill, Pollett, White, and N. C. Cookson.

CERTIFICATES AND AWARDS OF MERIT.

Odontoglossum Princess Christian (Baron Schröder).—A large flowered and beautiful variety with distinct blotches of chocolate brown (first-class certificate).

Dendrobium Ashworthianum (E. Ashworth, Esq., Harefield Hall, Wilmslow).—A pure white flowered variety with blooms in the form of *D. nobile* (first-class certificate).

Odontoglossum hybridum Ashworthianum (Ashworth).—Flowers with a pink lip and chocolate sepals, a curious and distinct variety (award of merit).

Odontoglossum Rochfordianum (Mr. T. Rochford, Turnford).—Flowers creamy, thickly blotched with brown, effective (award of merit).

Oncidium cuculatum (Frau Ida Brandt).—Plant had vanished when sought for purpose of description (award of merit).

MEDALS AWARDED.

Silver-gilt Flora medals were awarded to Messrs. William Paul and Son and Mr. G. Mount for Roses; to Captain Holford for Hippeastrums; to the St. George's Nursery Co. for Cyclamens, and to Messrs. J. James & Son for Cinerarias. Silver Flora Medals were granted to Mr. T. Rumsey for Roses, to Messrs. James Veitch & Sons for Clivias, and to Mr. H. B. May for Clematises. Silver Banksian Medals were adjudged to Messrs. Barr & Sons and Mr. T. S. Ware for Daffodils; to Messrs. J. Laing & Sons for wreaths and other ornaments; to Messrs. Hill & Son for Ferns, and to Messrs. Hugh Low & Co. for Orchids.

ARTIFICIAL MANURES.

WE daresay there are very few of the readers of the *Journal of Horticulture* who have not had a visit from some of the numerous artificial manure merchants. We have had a few, and if our experience is any criterion it is time more light is given to the subject, so as to enable those who have not had the facility for learning the "tricks of the trade," to understand something about what they are asked to buy. It is quite a common thing for some of these peripatetic manure vendors to promise to send the analysis of their fertiliser when they send you on the manure. We always consider that the man who cannot show us the analysis of the "stuff" we are asked to buy, so as to enable us to judge of its good, bad, or indifferent qualities, is not the one for us to deal with; and we think if the analysis is of any value, the owners will not mind showing it.

Last spring a traveller in the artificial manure trade called upon us with a Vine, Tomato, and a Chrysanthemum fertiliser. Of course there was nothing on this earth to equal his particular mixtures—indeed, the way he talked, one would have supposed he had a Klondike somewhere up in the north, and wanted us to share some of his gold; but although he stayed pestering us for nearly two hours, we could not be induced to take any. Some of our neighbours were less fortunate, and could not shake him off until they had promised to take a few cwt.

By an Act of Parliament passed in 1892 I believe every manure merchant is compelled to give an analysis to purchasers of more than 1 cwt. of manure. When the above merchant sent his mixtures he did not send an analysis, and of course this made the buyer suspicious. He wrote asking him to send one, but no notice was taken of his letter; another letter was sent, telling him that unless the analysis was sent by return of post the matter would be put in other hands. The analysis was sent, and on it was stated that the merchant guaranteed his mixtures to contain 1 per cent. of ammonia. Supposing his manure contained only the specified amount of plant food—viz., 1 per cent. of ammonia, its value to the purchaser would be 7d. per cwt., and yet the artificial manure vendor as good as told you he was giving you the stuff at 15s. per cwt. It should be added that the firm in question is not among those whose names are familiar to readers of the *Journal of Horticulture*.—W. DYKE.

[Our correspondent is quite right in his reference to the law on the subject, and we know of no respectable dealer who hesitates for a moment in sending an analysis of his product. We have ascertained this fact by a number of applications. From those peripatetic canvassers for orders who decline to furnish the information suggested, we should not be induced to "take any stuff."]

EASILY GROWN HALF-HARDY ANNUALS.

As the years roll on these popular flowers seem to be more largely employed for bedding purposes in both private and public gardens. It is well that this should be, for by turning half-hardy annuals to good account many a gardener who has a large flower garden to keep gay, and little glass accommodation, can achieve such satisfactory results as would be quite impossible under the older systems of bedding in which *Pelargoniums* and other tender plants played so important a part. A strong point in favour of many of these easily raised annuals is that they flower so profusely and continuously as to quite put to shame many recognised bedding plants which give ten times the amount of trouble. This satisfactory state of affairs has doubtless been brought about by the improved types which have recently been raised. Let us note a few of the more popular and easily raised.

AFRICAN AND FRENCH MARIGOLDS.—The older forms, though producing large and showy or prettily marked flowers, grew too tall for ordinary bedding arrangements; now, however, we have a race dwarf enough for any purpose. During the last two seasons I have thoroughly tested these miniature Marigolds, and have no hesitation in asserting that I know of no class of bedding plants which will give a more gorgeous and prolonged display of flowers from the time they begin to unfold their blossoms till sharp frosts spoil the whole beauty of the flower garden. Heavy rains, which ruin the beauty of many flowers, seem to have no detrimental effect upon Marigolds, as they look fresh and bright the following day, and present a marked contrast to many battered blooms around them.

For bedding purposes I strongly recommend the French miniature brown and orange. The plants seldom attain a height of more than 6 or 8 inches, and in each case the colours are those greatly in demand, because there are few bedding plants which supply them. The seed should be sown during the last week in March or early in April, in pans or boxes placed in a cold frame. When the plants are ready for pricking out, if the weather is rather cold, I sometimes dib them in boxes, but during favourable seasons I prick them out on a warm border, or in a rough frame formed with boards. A few stakes placed across the edges of the frame will then give the necessary support to mats placed on at night for protection.

An important point is to move the plants before they have become drawn, and afterwards insure sturdy growth by giving them plenty of room—6 inches apart I find a suitable distance. When the spring bedding has been removed I decide which beds are to be occupied by Marigolds; the surface of these is hoed and made level, but they are not dug. This practice prevents the plants becoming rampant, and induces them to flower early and continuously.

For large beds Webb's gold-striped French Marigold, of which I am able to give a typical illustration, is a very fine strain, the flowers being large, well built, and prettily marked. The plants grow to a height of about 18 inches.

African lemon and African orange are very showy for ribbon or mixed borders, or even for large beds where a broad edging can be given, but in order to obtain fine large flowers the soil should be dug and manured before planting. The plants naturally grow to a height of 2 feet, and cannot, therefore, by artificial means be kept dwarf without destroying their chief point of beauty—viz., the production of flowers of large size and brilliant colour.

ASTERS.—These ought to be grown by the thousand in gardens where various styles of bedding are carried out, as well as where cut flowers are in great demand. One set of plants will, of course, not give a long succession of flowers, and should not, therefore, be relied upon to produce a display throughout the summer; but for flowering during late summer and early autumn Asters are unrivalled, and it is just at those seasons that colour is often lacking in flower gardens. I have for some years made a practice of growing large numbers of Asters in boxes or pans placed in a cold frame, the first batch being sown during the first week in April and another a fortnight later. The seed is sown thinly, so that there is no need to prick the plants off until the weather is warm enough for them to be placed in the open ground. When this is done they are set about 6 inches apart, which induces them to maintain a sturdy growth. It is seldom that any of these Asters are used at the ordinary bedding-out time, but are kept in reserve for filling beds which become shabby, or to follow spring bedding plants which happen to flower later than the majority.

Let me give an example. At bedding-out time we may perhaps have beds of *Violas* in full beauty; these will go on flowering satisfactorily till July, when they often get shabby. Then is the time to clear them out and fill the bed with Asters, which will begin to flower in a few weeks, and fortunately they can be lifted with balls of earth and scarcely feel the check, even after the flower buds have formed. The dwarf bedding varieties sent out by firms of repute are excellent for the purpose. Large beds look very attractive when

planted with a broad band of the dwarf kinds and filled in with such fine taller types as *Victoria* and *Comet*. The white and pink forms of the latter I regard as the most beautiful of Asters, and each year they are more largely grown.

DIANTHUS HEDDEWIGI.—These beautiful flowers may be obtained in crimson, rose, salmon, and white shades of colour, and when in flower they are very rich in colour and showy in appearance. The seeds ought to be sown at once in order to get good plants by the end of May.

DWARF TROPEOLUMS.—Though these are commonly misnamed "Nasturtiums," they all the same make a good display in dry, hot seasons, but in wet ones they are not usually seen to advantage, hence many gardeners are cautious about planting them in a geometrical flower garden, still they are very desirable for planting in masses on borders or in dry positions. In poor hard soil they will often flower splendidly, while in rich garden soil they may be unattractive through producing too much foliage. The middle of April is quite early enough to sow the seed. I like to sow in boxes and transplant to their permanent positions early. *Aurora* (pale pink), *Scarlet*, *Cloth of Gold*, *Ruby King*, *King Theodore*, and *Empress of India* are some of the best dwarf varieties. Among tall growing ones the following make fine showy climbers—*Fairy Queen* (pale pink), *Lobbianum*, *Spitfire* (scarlet), *Golden Cloth*, and *Black Prince*.

PHLOX DRUMMONDI.—I find it necessary to make a distinction between the treatment given to the familiar type and the newer dwarf varieties. The latter do not grow very freely in the early stages unless sown in light rich soil, containing plenty of leaf mould and sharp sand. These should be sown at once in boxes, placed in cold frames, the seedlings pricked off at an early stage, and grown under glass till May. These compact varieties are extremely useful in the flower garden, as they only grow to a height of 6 inches, but require good culture to bring out their best qualities. They may be obtained in six distinct shades of colour. The taller growing varieties I sow thinly in boxes, and prick out on a warm border. They are charming flowers for cutting, and are abundantly produced till late in the season. It may not, perhaps, be generally known that the plants succeed well in town gardens when the soil is fertile.

STOCKS.—Old favourites are these, yet still much prized by many. The plants are gross feeders, and should be grown in good soil from start to finish. For this reason I like to sow in pans, and transplant on an old hotbed, protected by a frame, giving each plant plenty of room to develop without becoming drawn. The seed should be sown during March, and the plants fully exposed to air on all favourable occasions. *Perfection*, *Fire King*, *Snowball*, *Princess May*, *Improved Dwarf German*, and *Mont Blanc* are some of the best varieties among the Ten-weeked types.

ZINNIAS.—The end of March is early enough to sow these. I like to stand the pans in which the seed is sown in a frame where there is a little bottom heat, and when the seedlings are an inch in height place them singly in 60-sized pots. They then experience but little check when planted in their final positions—a matter of vital importance in *Zinnia* culture. *Sutton's Miniature Pompon*, which attains a height of about 9 inches, is a great acquisition for bedding purposes; and the large-flowered striped and tall double varieties supply quantities of beautiful flowers which are extremely useful in a cut state, as well as for border ornamentation.—H. D.

FIG. 56.—GOLD-STRIPED FRENCH MARIGOLD.

BIRMINGHAM SPRING SHOW.

MARCH 16TH AND 17TH.

THE second annual Bulb Show was held as usual at the Botanical Gardens, Edgbaston, on the 16th and 17th under most favourable conditions. The exhibits on the whole were an improvement on those of the previous occasion. A superb exhibit of Hyacinths, Tulips, and Narcissi in pots exhibited by Mr. R. Sydenham attracted much attention, as did an interesting collection of bulbs grown in ornamental glazed vases for table decoration in a mixture of cocoa-nut fibre, ground shells, and charcoal for drainage.

A most attractive and welcome feature was comprised of three collections of spring flowers in pots arranged for effect in a space not exceeding 30 square feet, both forced and naturally grown, the prizetakers in this class being Mr. A. Cryer, gardener to J. A. Kenrick, Esq., Berrow Court, Edgbaston, Mr. I. Priest, gardener to A. W. Hulse, Esq., Birmingham, and Isaac Cooke, Esq., Shrewsbury, in the order named. As may be readily conjectured, another highly attractive feature was the splendid display of non-competitive bouquets, wreaths, harps, and table decorations contributed by Messrs. Perkins & Son, Coventry. A collection of cut Narcissus and Daffodils, exhibited by Mr. R. Sydenham, added not a little to the general effect of the show.

For twelve single-flowered Hyacinths, distinct, Mr. W. A. Sarson, Moseley, secured the first prize for very good samples of La Grandesse, Princess May, Lord Macaulay, Vuurbaak, L'Innocence, King of the Blues, Grand Maître, Roi des Belges, Koh-i-Noor, and others. The second position was accorded to Mr. A. Ball, gardener to H. I. Horsfall, Edgbaston, the third being creditably taken by Sir John Jaffray, Edgbaston. For six pots of Hyacinths the first prize was won by Mr. S. Gibbs, gardener to J. B. Manly, Esq., Harborne, with fair examples of La Grandesse, King of the Blues, Fabiola, Queen of the Blues, L'Innocence, and Koh-i-Noor, the second going to R. Chatwin Cartwright, Esq., Selly Park, and the third to Mr. E. C. Fowke, Edgbaston.

For twelve pots of single Tulips the premier award was bestowed on Mr. A. Cryer, with very fine examples of Keyzers Kroon, Proserpine, Dusart, Joost Van Vondel, Cottage Maid, Ophir d'Or, Stanley, White Pottebakker, and Prince of Austria, whilst Messrs. I. Cooke and A. W. Hulse followed. For six pots Mr. E. Sharpe, Edgbaston, was placed first, Mr. E. C. Fowkes second, and Mr. Harvey Dubros third. The first prize collection consisted of excellent examples of Proserpine, Cottage Maid, Vermilion Brilliant, Keyzers Kroon, Joost Van Vondel, and Montresor.

For twelve pots of single Narcissi, not less than eight varieties, the first prize was awarded to Mr. A. Cryer with Golden Spur, Princeps, Mrs. Langtry, Figaro, Emperor, Barri Conspicuus, Sir Watkin, Henry Irving, Horsefieldi, and Grandee; whilst the second and third prizes fell to Sir John Jaffray and Mr. I. Cooke. For six pots the respective winners were Messrs. J. Sceany, E. M. Sharp, and R. Chatwin. For six pots of Polyanthus Narcissus Messrs. A. W. Hulse, R. C. Cartwright, and Isaac Cooke were the winners. In the class for collections of cut flowers of Narcissi Mr. Isaac Cooke worthily won the first position, the second being secured by the Rev. J. Jacob, Whitewell Rectory, Whitchurch, Salop; Mr. Chatwin Cartwright, the only other competitor, taking the third prize.

Pots of Lilies of the Valley were well shown, more especially the first prize six of Mr. A. Cryer, the second prize going to Sir John Jaffray, and the third to Mr. I. Cooke. Spiræas were fairly good, Messrs. A. Cryer, I. Priest, and I. Cooke taking the prizes. There were four collections of Cinerarias, the first prize being awarded to Mr. A. Cryer for well grown examples, the second and third prizes falling to Mr. G. S. Mathews, Edgbaston, and Mr. I. Cooke. In Mr. R. Sydenham's collection of Tulips the most notable were Unique, Proserpine, Stanley, Little Dorrit, Montresor, Golden Lion, Cerise, Gris de Lin, Duchesse de Parma, and Joost Van Vondel.

THE YOUNG GARDENERS' DOMAIN.

ON behalf of young gardeners permit me to render our hearty thanks to "An Old Boy" for his good, sound, practical advice to young men in the "Domain." I have had the pleasure of reading many previous articles which have appeared from time to time in the pages of the Journal, each of which was equally well filled with practical advice to young gardeners. I sincerely trust that his appeal will not be in vain, and I hope that ere many weeks have passed we shall see many new writers. I feel certain that nothing will be more gratifying for the "Old Boy" should this be the case, and let us hope that he will realise his expectations of us, and at some not far distant day take up his pen once more on our behalf.—J. F. D.

DAHLIAS.

THE Dahlia is a native of Mexico, and was discovered by Humboldt growing in sandy soils between 4000 and 5000 feet above the level of the sea. One variety flowered in 1789 under the care of that eminent botanist Cavanille, Professor and Director of the Botanic Gardens at Madrid, where he soon after flowered two others, and figured and described them in his "Scenes." From the Madrid gardens they were sent to the Jardin des Plantes at Paris in 1802, and in May, 1804, seeds arrived in England from Lady Holland, from which the first plants in this country originated.

The Dahlia may be propagated by seed, cuttings, division of roots, or grafting. The plants are very useful for adorning either the flower

garden or borders, to which they add a charming effect. They are of great value where cut flowers are in demand. In this case I think it advisable to plant in beds, the plants from 2 to 5 feet apart each way, according to the size of the varieties planted. They should be first started into growth in a temperature of 45°, gradually hardening the plants as the planting season approaches, and plant out as soon as the weather permits.

The soil most suitable for Dahlias is a good sandy loam not too rich, and which has been deeply dug and manured in the autumn. As soon as they are planted out each one should be neatly staked and kept well tied in during the growing season. When the flower buds appear an occasional watering of weak liquid manure and soot water will be very beneficial to the flowers. When growing for exhibition disbudding will have to be practised, and the flowers lightly shaded from the hot sun. They also require some protection from wet weather.—J. F. D., *Yorks.*

DWARF BEANS FOR EARLY WORK.

IN your valuable paper on April 8th, 1897, I wrote concerning the culture of this valuable vegetable, and was criticised by "Stone Warrillow" and "Single W." which I was glad to see. Now, "Stone Warrillow" and "Single W.," I am sending the Editor a sample of Beans, grown by the treatment I advised, and perhaps you would do likewise. What a fine chance we youngsters have to enlighten ourselves and to exchange our views in the "Young Gardeners' Domain." The Beans I send are Canadian Wonder sown in 60-pots. On January 4th, when about 5 inches high, they were potted into 16's and placed in the stove. I need not say more of the treatment, as it is recorded in the Journal for April 8th, 1897, page 301. I am sure the Editor will be judge for us.—W. W.

[The pods received were of first-class merit and a credit to the cultivator.]

BANANAS.

I HAVE been waiting several weeks for an answer to appear to your "Domain" correspondent's appeal for cultural notes on the above fruit. A few months ago I secured my present charge, and found myself similarly situated. I have two Musas growing in the stove in large tubs. In August last they showed fruit, which has been swelling slowly all the winter, but for the last two months appears to be at a standstill. The temperature of the house has been 65° by night, with a rise of 5° by day and 10° from sun heat. The plants have been copiously watered, and had liquid manure twice a week from the time the fruit started to swell up to the present. Is it usual for them to fruit at the time stated, or is it the result of bad management in the early stages of growth? If the fruit has now finished swelling, should they be cut, or allowed to ripen on the plant? Any information about them from a brother craftsman or an "Old Boy" will be gratefully accepted by—NIL DESPERANDUM.

ORCHIDS AT VINE HOUSE, HASLINGDEN.

A VISIT to this well-kept establishment, the residence of A. Warburton, Esq., is always full of interest to any lover of Orchids, and our visit recently was no exception. To enter into a full account of all the Orchids at Vine House would occupy far too much space, so it is intended only to give a short note of a few of the best in flower at the present time. We found Mr. Lofthouse and his assistants busily engaged arranging Cypripediums on a side stage in the Dendrobium house, which was until recently a Peach house, but the fruit has had to give way to Orchids. There was arranged a splendid collection of Dendrobiums, which was well worth a long journey to see. Very prominent were some grand specimens of the well-known and ever useful nobile nobilis and Wardianum. There were also two excellent specimens of D. n. Apollo—one a white, and the other a beautiful salmon colour, not yet named, but which will probably be heard of again. Several comparatively rare forms were observed in good condition, besides others which are often seen, but these need not be particularised.

Adjoining the Dendrobe house is one devoted to Cattleyas, in which there is not at present very much bloom. But there are some grand specimens from a cultural point of view. On entering one could not help being struck with a fine form of Cattleya Trianae alba. There were two fine spikes of Phaius Cooksoni, and a hybrid between C. Trianae and Mendeli, which is not yet named. From here we journeyed to the Odontoglossum house. Very showy on entering, suspended from the roof, were several pots of that little gem Sophronitis grandiflora, making a perfect blaze of colour. In a few weeks there will be a fine show in this house, there being hundreds of flower spikes showing. A fine specimen of O. Ruckerianum was very attractive, as was O. Andersonianum. There are many other Orchids grown well at Vine House which I might mention, but time and space forbid. Taken on the whole Mr. Warburton is to be congratulated on the excellence of his collection, and also the skill displayed in their culture by his energetic and capable gardener, Mr. T. Lofthouse.—J. C., *Lancashire.*

RHODODENDRON PRÆCOX.—Early flowers are always acceptable, and those who grow them would welcome the brief paragraph on this Rhododendron in a recent number of the Journal. With us in the North it is later than at Kew, but on March 5th it was fully covered with flower. But for the sharp frost which has occurred at night this early Rhododendron would have opened considerably sooner, as it was showing colour for some time before. Very beautiful is it now, and although the night frosts are yet keen they do not appear to do much injury to its bright purple blossoms.—S. ARNOTT.

HARDY FRUIT GARDEN.

Peaches and Nectarines.—*Protecting.*—The material employed for protecting the blossoms from frost should at once be affixed in front of the trees. The best method is that which utilises something moveable, so that light and air can be freely admitted on every favourable occasion. Scrim canvas or frigi domo are materials which will effectually exclude frost when they are dry, but they ought to be drawn up, or on one side during the day. Fish netting in double or treble thicknesses often proves sufficiently serviceable in warding off frosts at a critical time, and it has the additional advantage of not requiring daily removal, inasmuch as light and air can penetrate to every part of the trees. Whatever material is used it must not rest closely on the branches, though fish netting may be somewhat nearer without effecting any damage, provided wind does not blow it about. In the absence of a coping from which the protecting material can be suspended, poles may be placed against the walls well away from the trees at the foot, and firmly fixed in the soil. Over them stretch the material used, securing it firmly at each end and other points necessary for its safety.

Grafting Fruit Trees.—Large healthy old trees that fail to bear good crops, or produce fruit of some inferior or undesirable variety, may be induced to produce profitable crops of superior varieties by grafting. Very large old trees with thick stems ought, however, to have the branches shortened to near the point of grafting some time previously. All that is necessary then, when the period arrives for inserting the scions, is to remove a small portion of the branch, and the bark will be fresh and clean for the operation. The most commonly accepted method of grafting on branches of large diameter is crown or rind grafting. Several scions can be placed on one stock.

Preparing the Scions.—It is of the greatest importance to secure scions early in winter when perfectly dormant, preserving them in this condition until wanted for insertion as grafts. They are usually preserved in this way by laying them in soil under a north wall, only removing them for preparation previous to immediate insertion. The scions should be wood of the previous year, clean, uninjured, and in a well ripened state, with good bold buds. Usually the central parts of such shoots are the best, because the wood is firm, having bold buds. So far prepared the scion may consist of four buds. The lower end should be cut transversely. Just below the third bud commence a slanting cut to the base, forming a wedge. There only remains to be cut out a small piece of wood from the upper face of the slanting cut, this forming a seat by which the scion may rest securely upon the stock.

Preparing the Stocks.—The stocks having been cut transversely and the edges of the bark trimmed smoothly, make longitudinal slits downwards just through the bark the same length as the prepared portions of the scions.

Uniting Stocks and Scions.—The bark on each side of the incision for admitting the scion must be gently raised, pushing the scion carefully down until the upper end rests upon the stock. See that the inner bark or alburnous tissue of both stock and scion fits exactly on both sides if possible, but at least on one. Secure the united parts firmly with matting, and cover the whole well over with grafting wax or the preparation, which can be purchased ready for immediate use, known as Mastic l'Homme Lefort. All the joinings should be covered with the material and the face of the stock as well. This is very important, as the complete exclusion of air materially assists a speedy union.

Top-dressing Fruit Trees and Bushes.—The present is a suitable time to apply some fertilising material over the roots of trees and bushes that need assistance either to encourage freer growth during the succeeding season or to nourish the crop of fruit which the trees may subsequently carry. A mixture of fresh loam, decayed manure, and wood ashes proves of great benefit to Cherries, Apricots, Peaches, Nectarines, and Plums. Lime, chalk, or mortar rubbish may be required in soils deficient in calcareous matter, the latter being essential to stone fruits. The addition of a little bonemeal and muriate of potash is excellent for fruit bushes, including Red and White Currants, Gooseberries. They require to be fed liberally with phosphates and potash; bonemeal supplies phosphate. Black Currants need more liberal nitrogenous food in addition, owing to the necessity for them to form a fair amount of strong new wood each year, as well as perfecting the fruit. Similar dressings should be applied to Raspberries. Even without applications of chemical manures, bush fruits invariably succeed when farmyard manure is applied liberally over the roots and liquid manure given freely during growth. Liquid manure is excellent to apply to large old trees of Apples, Pears, Plums, which may have their roots deeper, especially when making deficient growth or showing other signs of enfeeblement.

FRUIT FORCING.

Figs.—*Earliest Forced Trees in Pots.*—Early Violet and St. John's, though small, are excellent first early varieties, and now as they advance towards ripening must be kept dry. This applies both to the foliage and the roots. Water, however, should be supplied to the roots so as to maintain

the foliage in health. Trees of Pingo de Mel and Brown Turkey swelling their fruits need full supplies of water and liquid manure until ripening commences, when a circulation of warm air will be necessary to secure well ripened high quality fruit. The temperature should be maintained at 60° to 65° at night, 70° to 75° by day from fire heat, 80° to 85° with sun, admitting air or increasing it from 75°, closing the house early so as to advance 5° to 10° afterwards.

Planted-out Trees.—These often grow too luxuriantly, and are frequently trained to walls at a considerable distance from the glass, so that they produce wood instead of fruit. This can only be overcome by lifting, restricting the roots, and training the growths thinly. When the foliage has abundance of light and the roots are plentiful in borders of limited area, the trees require liberal feeding. Fig trees with abundance of fibrous roots will take almost any amount of liquid manure without prejudice to the crop.

Vines.—*Earliest Forced in Pots.*—The canes started last November, and duly attended to in regard to heat, moisture, and other cultural requirements, have the Grapes swelled to a good size, and these are changing colour. The supplies of liquid manure should be lessened gradually, so as not to give a check, and the atmospheric moisture must be reduced. Allow a gentle circulation of air constantly, and damp the house in the morning and afternoon, as moisture is essential to the finishing of the Grapes. Maintain the temperature at 60° to 65° at night, 70° to 75° by day artificially, and between 75° and 85° through the day from sun heat, ventilating freely in fine weather.

Early Houses.—In the house started early in December the Grapes are rapidly advancing towards the colouring stage, and should be afforded a thorough supply of tepid liquid manure, mulching with a little partially decayed lumpy manure. With the border in a proper state of moisture and the stimulus given the roots, little, if any, further moisture will be needed by the border until the Grapes are cut. Continue damping at closing time until the Grapes are well advanced in colouring, after which reduce the moisture gradually, but provide a circulation of warm air by day and night.

Vines Started at the New Year.—When these are advanced to the flowering stage afford plenty of warm, rather dry air, with a temperature of 65° to 70° for Black Hamburgs and similar sorts, and 70° to 75° for Muscats. All shy-setting varieties should have their flowers gently rubbed with a camel's-hair brush. Varieties deficient in pollen may be supplied from those affording it freely. On no account allow the thinning to remain a day longer than is necessary to ascertain the best set bunches. Free-setting varieties, such as Black Hamburg, may be thinned as soon as the berries are formed, but Muscats and other shy-setting sorts ought not to be thinned until the properly fertilised berries are taking the lead. When the Grapes have been thinned, and are swelling, supply liquid manure in a tepid state, and mulch with about an inch depth of rather fresh lumpy manure, keeping it sprinkled from time to time, especially at closing the house. Admit air early and liberally as the heat increases, seeking to secure short-jointed wood and thick leathery foliage. Close early, with plenty of atmospheric moisture, raising the heat from the sun to 85° or 90°, and allow the night temperature to fall to between 60° and 65°.

Succession Houses.—Stopping and tying the shoots will need attention, not allowing these matters to fall into arrears, as large reductions of foliage are pernicious. Where the growth is somewhat restricted stop two joints beyond the bunch, pinching the laterals to one leaf; but where there is space for extension allow four or five joints beyond the fruit. After the space is occupied keep the growths stopped to one joint. Supply water or liquid manure to the inside border in a tepid state, and ventilate freely on all favourable occasions.

Late Houses.—Late Grapes started as previously advised will be swelling their buds. Syringe the Vines twice daily, and every surface ought to be damped in the morning and evening, closing the house with plenty of moisture at 75°. Inside borders will need repeated waterings to bring them into a thoroughly moist condition. A supply of liquid manure will materially assist weakly Vines, supplying it after making the border fairly moist. Outside borders must have a light mulch of some protective material.

Strawberries in Pots.—The north-easterly winds have not been favourable to plants in flower, mildew flourishing, and sulphur is much less effective against it in winter than in summer. In dull weather it is well to shake the flowers occasionally when the pollen is ripe, and to remove the smallest and least desirable, leaving the boldest, which are usually the first to expand, and they generally afford the largest fruit. Thin the fruits after they are set, leaving the number on each plant it is calculated to mature well. Colour and size are the chief points in a forced Strawberry, and a relatively few good fruits are better than many indifferent. The plants should be examined twice a day for water, supplying it where needed liberally, affording liquid manure two or three times a week when the fruit is swelling. Steady progressive growth is most favourable for Strawberries until after flowering, then they swell better in a high temperature, and moist but not very close atmosphere.

COMMON MISTAKES IN FRUIT CULTURE was the subject of a practical and instructive paper given by Mr. George Bunyard of Maidstone before the Reading and District Gardeners' Mutual Improvement Association on Monday evening last. Mr. C. B. Stevens presided over a large attendance of members. The paper was followed with the closest attention, and at the close a hearty vote of thanks was accorded to Mr. Bunyard.

THE BEE-KEEPER.

WORK IN THE APIARY.

It is an advantage at this season, before the busy time commences, to make a note of the necessary work to be done in the apiary, and also the requirements for the coming honey harvest. Owing to the fine weather experienced throughout the winter the hives standing in the open air are dry and in good condition for painting. We prefer autumn for this operation, as the heat from the sun will often cause the wood to crack, and the first fall of rain or snow will saturate the interior of the hive. There is nothing so penetrating as snow, but fortunately we have escaped a downfall during the past winter. But rain may be expected at any time; it is therefore wise to take time by the forelock and make all secure against wind and rain. It is not necessary to remove the hives under cover whilst this is being done, nor should the bees be interfered with, as the hives may have one or more coats of paint without any harm happening to them.

Good white lead paint is the best for outdoor work, as it stands heat, cold and moisture better and longer than any other mixture. Enamel paint is sometimes recommended, but however well it may answer when under cover free from sun and moisture, it is certainly not a success when used in the open air. The paint should be well worked into all the crevices, and if the roof is cracked or damaged in any way so that it is not watertight, it may be made perfectly secure if a piece of unbleached calico is placed over it and well saturated with paint. The most successful way of doing this is to cut the calico the desired size and paint it on one side, then place the wet side on the roof or whatever is to be covered, and strain it tightly over; another coat of paint on the outside will make it secure against wind or rain. Neither will it warp with the sun, while an occasional coat of paint will keep it in good condition for several years. This is of great advantage, as all bee-keepers know who have been troubled (and who has not?) with leaky roofs. A word of caution is necessary, not to paint the alighting board, or the entrance to the hive, unless it is done late in the evening when there is no danger of the bees leaving their hives.

EXAMINING OLD COMBS.

Another of the necessary things that may with advantage be done at this time, is the examination of combs that have been used in former years for extracting and other purposes, and have been stored away in boxes or cupboards for future use. Unfortunately mice are very fond of combs and honey, and have a happy knack of finding out where they are stored, and if there is a crevice through which they can nibble an entrance, if left undisturbed for a short time, will soon make their presence known by consuming the honey, if any remain in them, and disfiguring the combs, so that they are useless for the purpose for which they were intended, hence the necessity of an occasional examination. It is good practice to lift the frames out of the boxes or wherever they may be stored, and brush the dust from them; and if they were packed away as advised in previous notes, the same steps may be taken to prevent the moths gaining an entrance, as was taken in the autumn when they were first stored away.

We use unbleached calico for lining the boxes in which the combs are stored; this is sprinkled freely with carbolic acid, the combs are then placed in the box, and when the box is full carbonised cloths are placed over them. This is an inexpensive way of storing combs for future use, though there are other systems that are used for the purpose of keeping the wax moth away. Care must be taken that the carbolic acid is not sprinkled on the combs, otherwise it will be difficult to make them sweet again.

REDUCING ENTRANCES.

Entrances that have been left their full width throughout the winter may now be reduced to 1 or 2 inches, according to the strength of the colony, as owing to the open weather experienced throughout the winter each individual stock will be stronger than usual at this season, and breeding will be proportionately early. By reducing the entrances it will have a double advantage—namely, keeping the interior warmer; and also in the case of a weak colony preventing robbers gaining admittance, as it is well known how readily a strong stock of bees will clear out the stores from a weak colony. This is more prevalent during spring and autumn.—AN ENGLISH BEE-KEEPER.

HEPATICA ANGULOSA MAJOR.—The large-flowered variety of *Hepatica* or *Anemone angulosa* is now in full bloom. It is to be regretted that it does not flower so profusely as the varieties of the common *Hepatica*, and that no one has as yet been able to recommend treatment to overcome this failing.—A. HARDIMAN. [We have observed bees very busy on *Hepaticas* of late, but do not know if this is a common occurrence.]

TO CORRESPONDENTS

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8, Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Wednesday Morning's Letters.—Letters and parcels which arrive on Wednesday morning can rarely be attended to, and replies published in the current issue. Some parcels and letters are delayed in delivery through being misdirected. The correct address for everything intended for the Editor is given above.

Brunswick Figs Collapsing (Wilts).—Mr. Wythes finds this variety to fail in the same way as yours if any material extent of growth is permitted beyond the fruit. He pinches very closely, about 2 inches beyond the first crop fruits, and allows of any needed growth extension afterwards. Excessive syringing aggravates the evil. This is all that can be said at present. The subject shall have further attention.

Cucumber Pests and Red Spider (A. R. W.).—There is no book treating of Cucumber pests and diseases, but most of them have been dealt with from time to time in our columns, and "red spider" has been frequently referred to. But of this you will find a full account in Miss Ormerod's "Manual of Injurious Insects," page 135, and also in most works on gardening. We are always pleased to report on any specimen submitted to us, and advise as to prevention and remedies, this often being more to the purpose than reference to technical works which do not give information on the particular points desired in special cases.

Deformed Vine Shoots (S. D.).—The three young shoots are free from any disease of an organic nature, but are what is known as "lagging"—that is, not so forward as the generality of the growths, and have a stunted appearance. We have found it most prevalent on young Vines, especially when strong and long pruned. The canes have usually a large pith, with the wood along it more or less dried, so that sap does not flow freely in the vessels, while the cambial layer is thin, and the growths poor in consequence. In other words, the condition arises from indifferently formed and imperfectly ripened wood. As the soil is rather heavy, we should use water moderately, so as to avoid sappy growths, securing a sturdy development.

Dwarfing Tomatoes (S. German).—The plan you propose to follow will answer very well if you give plenty of air as well as restrict the pot room. Encourage surface root formation by the top-dressings of loam, calcareous and sandy material, this tending to stiffen the plants and induce a short-jointed floriferous habit. We should not use sulphate of ammonia, but a little dissolved bone manure, this containing sufficient stimulating food, adding about half as much nitrate of potash, and giving a slight dusting of the mixture, or better mixing a small handful with about a peck of the loam used for top-dressing. In planting out take care to have the soil firm, so as to maintain the sturdy habit and secure solid growth.

Chrysanthemum Leaves Discoloured (H. H. M.).—The leaves of the three plants are discoloured by some injurious application, most likely by using the water drawn directly from the hot-water pipes, an extremely pernicious practice, as the water is more or less impregnated with iron or in a state as to cause "rust" and death in foliage with which it comes in contact. This, and this only, appears all that is wrong with the plants, as there is no parasitic micro-organism present, the mould on the dead leaves being entirely saprophytic, or only attacking tissue already damaged or killed. There is certainly no leaf rust fungus (*Uredo chrysanthemi*), and in this respect we congratulate you, also on discontinuing the use of water from the hot-water pipes, and in trying that from a different source. This, we trust, is soft and sweet; then by not syringing, you may secure clean healthy growth.

Dendrobium nobile (W. J. P.).—The varieties of *Dendrobium nobile* sent are very fine. No. 1 comes very near to the variety *nobilis*, and we would like to see it another season. No. 2 is *D. n. albiflorum*, the purplish tips being not unlike those of the sub-variety *Rajah*. They are both much above the average. All the flowers sent indicate cultural merits, for they are clear in colouration and of good substance.

Lilium speciosum rubrum (Amateur).—You are right in supposing this to be synonymous with *L. lancifolium rubrum*. In the majority of instances you will find a 6 or 7-inch pot will do for a strong bulb of this *Lilium*. Drain the pot well, and on that place some rough peat and loam, filling the pot about half full. On this set the bulbs, and just cover all except the point, and then set the pots on the floor under your stage, and give little water until the stems begin to move; then bring them into the light, and earth up as the stem grows. After the end of May a sheltered place out of doors will suit them as well as the greenhouse or cold pit. When growing freely they require plenty of water.

Carnation Cuttings (D. S. R.).—The best cuttings of Perpetual flowering Carnations are those 3 or 4 inches long, detached with a heel, cut transversely or pared smooth, the lower pair of leaves being removed. The compost should consist of turfy loam, leaf soil, and sand in equal parts (mixed), and just moist, not wet. Insert each cutting in a thumb pot, using a little sand; press firmly, and plunge the pots two-thirds their depth in cocoa-fibre refuse in a frame kept close, and with a bottom heat of about 65° to 70°. In four days if bright, or a week if dull, the cuttings may be watered, giving enough to moisten the whole of the soil, leaving the lights off until the tops of the cuttings become quite dry, then replace. Continue this procedure until the cuttings are rooted, then gradually inure them to the air of the house, harden and shift into larger pots.

Spotted Tomato Leaves (Wakofa).—The four leaves are not infested by any cryptogamous parasite or animal micro-organisms, but quite normal, the spots being due to defective chlorophyll development, this probably arising from the cause you name—that is, comparative soil exhaustion through the plants being rather root-bound. The high temperature would have a tendency in the direction referred to and not do any harm, provided the ventilation corresponds to the heat and allows evaporation of moisture to proceed from the leaves. This hardening process renders the plants more disease-resistant, and has a deterrent effect on certain fungi, especially the most hurtful, such as the Potato disease fungus, *Phytophthora infestans*, and also on "black stripe" parasite, whilst promoting an early floriferous habit as the result of the higher elaboration and concentration of the juices.

Growing Buckwheat as Food for Poultry (W. H.).—Buckwheat (*Polygonum Fagopyrum*) was first brought to Europe from Asia by the Crusaders, hence it is often called Saracen corn. The plant will not endure our spring frosts nor those of early autumn, hence the seeds must not be sown till warm weather sets in during May. The flowers appear about July, and are excellent for bee flowers. The seeds ripen in late September or October, but so tender are the plants that a single night's frost will destroy a whole crop. It is best sown in drills similar to Beans, the plant growing about 30 inches high, and producing small triangular grains of a brownish black without and white within, in great profusion, much relished by partridges, pheasants and poultry, hence buckwheat is commonly grown near preserves for winged game to feed on to their heart's content. English grown seed is best, and two bushels will sow a statute acre. Gamekeepers get the land into good tilth by the middle of May, then either drill the seed or sow broadcast and lightly harrow in, and keep the ground clear of weeds. Light sandy soil just suits Buckwheat, as it likes warmth, and seeds all the better in poor rather than rich land. The seeds are excellent food for poultry, as also are Sunflower seeds; we have grown both largely for fowls and game.

Leaves of Buckland Sweetwater Vines (G. C.).—The leaves are suffering from what is known as browning or "brunure." We failed to find anything of an organic nature, certainly not any fungus, and the slight stain in the cells hardly betrays the presence of *Plasmidiophora vitis*. Therefore we should attribute the effect to the constitutional defects of the Vine, the variety not being so strong as many others, and has been prejudicially affected by the roots having to collect nutrition from an outside border. We have noticed it before under similar circumstances, and in this variety more than other Sweetwater Grapes. It also arises from the house being kept rather close and moist for several days, and then on a return of bright weather the admission of air, no matter now carefully, causes a relatively excessive evaporation, what is generally termed a chill. Really, however, the roots do not supply the requisite amount of water, and the tender growths suffer in consequence. The only really effective preventive in respect of this variety in an outside border is to have it on the Black Hamburgh, on which we find it to succeed better than on its own roots, and even inside the Vines suffer more from "brunure" than other varieties except Muscat of Alexandria.

Names of Plants.—We only undertake to name *species* of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once,

and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (R. C. N.).—*Leucathoea Catesbaei*. (F. G.).—*Oncidium luridum*. (Young Gardener).—1, *Ilex aquifolium*; 2, *I. a. ferox argentea*; 3, *I. a. crispa*; 4, *I. aquifolium*, variety unknown; 5, *I. a. nigrescens*; 6, *Cupressus sempervirens*. (C. G.).—1, *Kerria japonica* fl.-pl.; 2, *Aucuba japonica* (male form); 3, *Cedrus atlantica glauca*; 4 and 5, slightly differing forms of *Abies sachalinensis*; 6, *Berberis Darwini*. (E. H.).—*Staphylea colchica*, a hardy deciduous shrub extensively employed for forcing.

OUR HORNED STOCK.

In the summer season the whole country is alive with agricultural shows, big and little, from the exhibition of the Royal Society of England to the small village foal show. These are all of great educational value, provided they are used in a proper spirit. Only the choicest and best of everything is seen, and the competition is at times so severe that only *la crème de la crème* finds place or position. So far so good, but does the object of the show end when

the ribbons and medals and prize money have been distributed? Hardly. We show the best sires and dams we can produce as a stimulus to others to follow our line, and to do as well, if not better. But this is all of little use, and the show yard an empty object lesson, if people will go on year after year breeding on the same old lines; breeding in-and-in, and knowing little, and caring less, what sort of stock they have as long as it is stock.

Nothing will get over the fact that a badly bred horse or beast will consume just what a good one does, and in the long run hardly realises what will pay for his keep. "Penny wise and pound foolish." We see it again and again. How many homesteads may we visit and find all the draught horses old, worn out, with many, many screws loose; and on a winter's day a look in at the crew yard is very instructive as to the "how not to do it." It is just the same all through the category, even down to the mongrel sheep dog. It would be a queer herd if there were not some cows of fairly decent type, and if their weak points were taken into consideration when the choice of a mate was made there would be every chance of improvement in the progeny.

Surely this is not a hard matter—it is a poor neighbourhood if it cannot produce a few good sires whose services can be had at a reasonable fee. Nothing pays better for an ordinary farmer who grazes part and milks part than the purchase of a really good Short-horn bull. Surely there are sales enough over the country, and it does not take the wisdom of a Solomon to pick out a decent beast. If money is an object buy a six or nine months old calf; his keep will not amount to much, and he will grow into money. If you have no reliance on your own judgment there are plenty of auctioneers who will get you the right article on commission, and probably at a less figure than you would yourself.

To anyone who knows much of agricultural movement, the name of Sir Jacob Wilson is familiar. Of a good old Northumberland family, years ago he was the Northumberland Agricultural Society, its life, its moving spirit. Nothing makes a show go like an active secretary, and he raised the Northumberland Show to a high position. Public duties made him relinquish his post some years ago, but the spirit of enterprise is still alive, and it has fallen to the lot of that society to make a new movement which must prove of the greatest possible benefit to the tenant farmers of the county. It is only right that the Northern counties should take the initiative in this matter, for to them belongs the glory of all the traditions of the first Shorthorn breeders.

The Society has resolved to devote the sum of £300 to the purchase of pedigree bulls for the use of the farmers of the county. Members of the Society are expected to pay a fee of 4s., and non-members whose rental does not exceed £50. Now this last we think is a grand idea. The richer farmer would not be likely to grudge a fairly large service fee; but to the poor man, whose shillings are few, the fee is of great moment, and it is so necessary that he with his one or two cows should be able to make the most of their produce, and get his young stock early into the market. Badly bred beasts, like Pharaoh's lean kine, are never fat. One bull within a radius of five miles. He is to be kept by a farmer who will receive as payment for his keep the service fees. Is not this a much better plan than the one that has been suggested—namely, that animals should be provided on the same lines as the Queen's premium horses? We think so. We have always advocated that self-help is by far the most valuable. We do not much believe in the bounty system, and surely other agricultural societies might take example, and go and do likewise.

If we mistake not, a few years will show such improvement in the stock of Northumberland farmers as will surprise many weak minds. We need only instance what has been done in our own neighbourhood in the matter of draught horses since the introduction of a Shire horse stud by a landed proprietor. At the annual local show can be found mares and foals fit for any company, and buyers are attracted from all parts. Times do not allow of any second-class stock; the best, or none at all.

We have just been reading a few statistics of the stock revival in

the States, and we must bear in mind six days will bring a cargo from New York to Liverpool. If we fail to provide meat, America is ready, and increasingly ready. January 1st, 1898, shows an increase in the value of horses, mules, cattle, sheep, and pigs of £30,000,000 over the January of 1897. All their stock is increasing in value per head. They are tired of breeding inferior cattle, and will now only have the purest and best. Texas can show a million more cattle than are found in all England, and the State of Iowa, which is by no means a large one, can produce as many as we have. The States, as a whole, have 32,000,000 cows in milk, and of a good type. The Americans have found out that there are cows and cows, and they intend that their dairy cows shall be real "fill pails."

No wonder we see plenty of American bacon with 50,000,000 pigs, and power to add to their numbers; truly these figures are stupendous. They always do things on a big scale in America. We cannot hope to beat them in numbers, but we still think we might do a good deal to beat them as to quality.

WORK ON THE HOME FARM.

Very sharp frosts and dry warm days have been the rule the last week. We have stopped the drill, as the frost has not disappeared generally until ten or eleven o'clock, and the land is still a little rough. The fact is, we want rain to make drilling go really well, and a nice soaking would do good everywhere. We can hardly expect to get enough to replenish the springs, for they are very low, some being already dried up. This is a very serious state of affairs, and nothing but a moist summer can save us from very great inconvenience, if not disastrous loss of stock, for without rain a water famine there must be.

We never knew such a favourable time for cleaning land, and little remains to be done in that direction. The dry condition of the soil is in favour of ploughing down land meant for Turnips, and leaving it as close and firm as possible until almost the time to sow; the moisture will thus be best retained, and no chance of a Turnip plant will be thrown away.

Potatoes are being planted very favourably, as we like to see them in a dry seed-bed if the tilth be good. We are giving phosphate and kainit with the sets, and shall give nitrogen as a top-dressing. We are planting Up to Date on the weakest land; it is inclined to get too large on good soils. We are putting Elephants into the medium, and Her Majesty into the best soils, whilst we are not entirely forsaking Bruce, which has proved a good friend under very varying conditions.

Lambing progresses slowly but satisfactorily; the crop is not heavy but fair, and losses so far are insignificant.

A cow which presented us with twin calves last year has done the same again; the juveniles are small but healthy, and we should like the mother to continue in such a good way.

Roots are still plentiful, though not quite so abundant as a month ago, and pastures having been much cut by frost there is a little anxiety in some quarters as to the April food supply. Feeding sheep have never done better than this winter, roots have been sound and good, and layer has been so dry that lameness can but have been caused by culpable neglect.

REMARKS.

- 13th.—Overcast morning; sunny afternoon, and fair evening.
 14th.—Overcast, with spots of rain early; showery between ten and noon; generally sunny from 1 P.M.
 15th.—A little fog early, but sunshine nearly throughout; halo in afternoon.
 16th.—Alternate cloud and sun, and threatening about 1 P.M.; clear night.
 17th.—Overcast morning; occasional sunshine in afternoon.
 18th.—Fine, and frequently sunny.
 19th.—Generally overcast morning; drizzle from 3 P.M., and almost continuous rain from 4 P.M. to 10 P.M.
 A fine week, and the latter part warmer; rain still below the average.—
 G. J. SYMONS.

LAXTON'S STRAWBERRIES

FOR PRESENT PLANTING.

To effect a Speedy Clearance we are offering at
MUCH REDUCED PRICES, as follows—

THE GRAND NEW MONARCH, finest main
crop; strong open ground runners, 10/- 100;
in pots, 15/- 100.

Also the following, all in pots, to fruit the coming
season, so long as unsold—

VICOMTESSE H. DE

THURY,
ELEANOR,
JAS. VEITCH,
LATEST OF ALL,
SCARLET QUEEN,
BRITISH QUEEN,
COMPETITOR,
NAPIER,
MCMAHON,
COMMANDER,
LA FRANCE,

No. 1,

KEEN'S SEEDLING,
LA GROSSE SUCREE,
PRESIDENT,
KING OF EARLIES,
ELTON PINE,
DR. HOGG,
SOUV. DE BOSSUET,
J. RUSKIN,
ED. LEFORT,
AND
ROYAL SOVEREIGN.

Packed with the pots at 10/- 100, or turned out of pots and
packed with balls to roots, 8/6 100. Packing 1/4 per 100
extra. OPEN GROUND RUNNERS of most of the above,
at 2/6 100.

FULL CATALOGUE GRATIS.

LAXTON BROTHERS, BEDFORD

LONDON FERN NURSERIES,

LOUGHBOROUGH JUNCTION, LONDON, S.W.—Ferns, large
and small, in variety; Aralias, Grevilleas, Cyperus, Ficus,
Ericas, Palms, Dracaenas, Aspidistras, Hydrangeas, Pelar-
goniums, Fuchsias, Marguerites, Crotons, &c. Trade,
send for Wholesale List. Special List for Amateurs, send
for one.—J. E. SMITH.

LARGE EVERGREENS
FOR PRESENT PLANTING.

WM. PAUL & SON

Bag to offer the following, of

Best Quality and Regularly Transplanted,

At the annexed very Moderate Prices—

AUCUBAS, Green and Variegated, 4 to 5½ feet, 5/- to 10/6
each; 54/- to 108/- per dozen.
ARAUCARIA IMBRICATA, 5 to 7 feet, 10/6 to 15/- each.
ARBORVITÆ, AMERICAN, 9 to 10 feet, 48/- to 60/- dozen
WAREANA, 5 to 6 feet, 30/- to 42/- dozen.
BOX, GREEN, 5 to 6 feet, 30/- to 36/- per dozen.
HANDSWORTH, 5 to 7 feet, 30/- to 72/- doz.
VARIEGATED, 5 to 6 feet, 30/- to 42/- per dozen,
CEDRUS ATLANTICA, 10 to 12 feet, 15/- each.
DEODARA, 10 to 12 feet, 15/- to 21/- each.
CUPRESSUS LAWSONIANA, 8 to 10 feet, 60/- to 84/- doz.
ERECTA VIRIDIS, 5 to 6 feet, 60/- to 72/- doz.
HOLLIES, GREEN, named varieties, 6 to 8 feet, 72/- to 96/-
per dozen.
JUNIPERUS CHINENSIS, 8 to 10 feet, 72/- per dozen.
LAUREL, 5 to 7 feet, extra bushy, 30/- to 42/- per dozen.
PORTUGAL, 4 to 5 feet, 24/- to 36/- per dozen.
LAURUSTINUS, 3 to 3½ feet, 36/- per dozen.
OSMANTHUS ILICIFOLIUS, 4 to 6 feet, 36/- to 72/- dozen
PICEA PINSAPO, 10 to 12 feet, 15/- to 21/- each.
RETINOSPORA PLUMOSA AUREA, 6 to 7 feet, 60/- to
72/- per dozen.
YEW, ELEGANTISSIMA, 3 to 5 feet, 36/- to 108/- dozen.
GOLDEN, 3 to 6 feet, 36/- to 96/- per dozen.
GOLD IRISH, 3 to 6 feet, 30/- to 72/- per dozen.
RHODODENDRONS, finest named kinds, handsome and
well set with bloom buds, 4 to 5 feet, 8/6 to 15/-
each; 96/- to 150/- per dozen.

WEBBS'

NEW SUPREME ANTIRRHINUM,

A Charming Novelty. 1/- per Packet, post free.

WEBBS', WORDSLEY, STOURBRIDGE

A ZALEAS AND CAMELLIAS.—Grandly
budded stuff to name, 24/- and 30/- per dozen. Illus-
trated Catalogues of Stove and Greenhouse, including many
new and rare plants, free on application.—A. J. A. BRUCE,
The Nurseries, Chorlton-cum-Mardy, near Manchester.

ASPARAGUS.—This delicious vegetable does not
require half the expense usually incurred. For
simple instructions see SEED LIST, free on application.
Strong roots from 2/6 per 100.—RICHARD SMITH & CO.,
Nurserymen and Seed Merchants, Worcester.

IMPORTANT TO MUSHROOM GROWERS.—
CUTHBERT'S SPECIALITE MUSHROOM SPAWN.
Always alike; most productive. Hundreds of Testimonials.
Per Bushel, 5/-.—R. & G. CUTHBERT, Seed, Bulb, and
Plant Merchants, Southgate, N. Established 1797.

100,000 BEGONIA TUBERS.—Large, erect
flowering. Single, 12 for 2/3; 100, 16/-.
Double, 12 for 2/6; 100, 17/-. SEND FOR LIST, FREE.—
JOHN WELLS, Begonia Nursery, Ryarsh, Malling, Kent.

HEATING APPARATUS.—Medals 1875 and
1881. Catalogue of Boilers, Pipes, and Fittings free.
W. Jones' Treatise, "Heating by Hot Water," second
edition, 216 pages, 2/6; post free, 2/10.—JONES and
ATTWOOD, Stourbridge.

PURE WOOD CHARCOAL, Specially Prepared
for Horticultural use. Extract from the *Journal of*
Horticulture: "Charcoal is invaluable as a manurial agent;
each little piece is a pantry full of the good things of this
life. There is no cultivated plant which is not benefited by
having Charcoal applied to the soil in which it is rooted."
Apply for Pamphlet and Prices to the Manufacturers—
HIRST, BROOKE & HIRST, Ltd., Leeds.

PROTECT YOUR GARDENS.—Garden Netting,
oiled and dressed; will not rot if left out in all
weathers. 100 yards by 1 yard, 3/-; 100 yards by 2 yards,
6/-; 100 yards by 3 yards, 9/- Or so on to any width.
Carriage paid on all orders over 5/- I do not require payment
till you have received and approved of the netting from—
HY. J. GASSON, Garden Net Works, Rye.

ALL WHO WISH GRAND RESULTS should
use THOMSON'S IMPROVED VINE, PLANT and
VEGETABLE MANURE. This Valuable Manure is yearly
growing in public favour. Can be had of all Nursery and
Seedsmen, or direct from the makers, WM. THOMSON and
SONS, Ltd., Tweed Vineyard, Clovenfords, Galashiels,
N.B. Price Lists and Testimonials on Application. 1 cwt.
and upwards Carriage Paid to all stations in Britain and
Ireland. London Agent—Mr. J. GEORGE, 14, Redgrave
Road, Putney. Agent for Channel Islands—Mr. J. H.
PARSONS, Market Place, Guernsey. Also THOMSON'S
SPECIAL CHRYSANTHEMUM MANURE. ½ cwt.
Carriage Paid to all stations in Britain and Ireland.

London, post free for a Quarter, 3/9. Editorial
communications must be addressed to 8, Rose
Hill Rd., Wandsworth, S.W.

WINTER AT LAST.

PROSPECTIVE FRUIT CROPS.

MANY have been the rejoicings over the
remarkable, if not unexampled, continuance of
balmy days throughout the period which, accord-
ing to custom, ought to have been winter. On
another page of the present issue of the *Journal*
of *Horticulture* a meteorological correspondent tells
us that at his salubrious station on the south-west
coast—Torquay—the temperature of the past five
months—October to February inclusive—has been
upwards of 14° above the mean average of twenty-
two years' observations. This may be taken as
fairly representative of the "winter" throughout
the country generally, for the abnormal mildness
seems to have prevailed in Scotland about equally
with the South of England.

The effect of it was to bring records, in shoals,
from practically all parts of the kingdom, including
the Emerald Isle, of the wealth of flowers in gardens
and fields. Sunny banks appear to have yielded
Violets and Primroses all the time, and summer
Roses did not cease blooming in favourable positions
until the real winter came, in what the calendar
tells us ought to have been spring. It was felt and
believed by thousands of people, more particularly
those with minds still young, that spring—the
real "spring of gladness and hope"—had come
before its time, and come to stay.

Even some, and perhaps not a few, persons who
have passed the meridian of life may have been
half beguiled into the hopeful belief that winter
had done its best, or worst, to gain pre-eminence.
Yet there were lurking misgivings. He was not a
youth who wrote about a month ago, "With all
the charms incident to the season, spring some-
times has an unkind welcome. Winter yields not
the sceptre without a struggle, and many are the
combats between the two. There are advances and
retreats on both sides; days of sun and soft rains,
days of gloom and snow showers; nights of
mildness of calm and nights of frost and storm.
Still, inch by inch winter has to yield." Nothing
could be more truly descriptive of the fitfulness of
March weather than that, and no prognostic more

No. 2583.—VOL. XCVIII., OLD SERIES.

sure of realisation, though the victory of spring was not so near as the cautious writer appears to have thought.

He could not have anticipated the violence of the onslaught—let us hope a last despairing effort of determined winter to assert its crushing power—than that which overswept land and sea on Thursday night last. A “night of frost and storm” it surely was, followed by a day of “gloom and snow showers” driving with bitter and relentless force not soon to be forgotten. No one during the flowery days of February was bold enough to predict that before March was out trains would be snowed up in railway cuttings, and country roads rendered impassable for a time by drifting snow; yet such was the chilling fact.

The 25th inst., when the almanack spring was four days old, was truly described in one of the newspapers as “in every respect worthy of midwinter in its most dreary aspects.” Snow fell all the morning, the north-easterly wind driving it and the subsequent sleet to and fro with such fierceness that some of the hardy ’bus drivers of London were driven in turn to resort to the feminine protection of gauze veils. At no time did the thermometer rise more than 4° above the freezing point, and the day is said to have been the coldest that has been experienced in March since 1879.

Reports state that in the Thames Valley such a formidable blizzard has not been experienced for many years, and that much damage was done to the trees in the royal parks of Bushy and Richmond, while in Kew Gardens the damage sustained is said to have been very considerable. From Ashford, in Kent, we are informed that in addition to the snow filling the roads and stopping traffic, the frost was of such severity as to destroy the buds of Apple, Pear, and Cherry trees over a large area of plantations, and the fruit crops must consequently be a complete failure. We hope the results will not be so serious as are at present feared, and suspect that, generally speaking, sufficient fruit buds will be found to have “weathered the storm,” but the crucial time for fruit blossom is not yet over.

That March is a month of “many weathers” is proverbial, and seldom can there have been greater contrasts than have recently been experienced. On the first day of the month the radiation temperature in the sun was 85·6°, and on the third day 87·3°, while on the 16th and 18th it exceeded 91°; on the 20th it rose to 92°, and even on the 24th, 83·6°; but on the very next day we were plunged into the bitterest winter of the season, a fall to the minimum shade temperature of more than 54°. Fortunately low night temperatures had prevailed for some time previously, for had the spring-like weather of February continued much longer the effects of the recent frosts and driving ice winds on fruit trees must have been disastrous. The cold wave that cut short the beauty of spring flowers was just in time to check and retard the too precocious blossom buds, and may still prove, as we hope it will, to have been a blessing in disguise.

In one respect, and an important one, the fall of snow and rain must do great good in many districts. The under stratum of soil was never drier at the season of the year than it is now, and the roots of trees in many orchards and gardens can only be reached by heavy and continuous rains. If these do not come, the possible danger of loss of fruit through spring frosts that yet may occur will not be the only danger to be feared, for fruit may set, yet fall in shoals through lack of adequate moisture in the soil where the roots are searching for it to meet the requirements of foliage and fruit.

Orchard trees cannot be effectively watered, but it may be well to give a thought to fruit trees against walls in dry locations. The rainfall is greatly in arrear, the springs in many places are as feeble as they were at any time last summer, watercourses as low, and the subsoil over a great extent of country as dry as the time-honoured bone—a condition the reverse of favourable to the setting, and especially the swelling of fruit.

A gentleman had a fine Cherry tree, that was white as a sheet with blossom annually, but for years the incipient fruits were shed. The subsoil on examination was as dry as powder. He was advised

to make numerous deep holes with a crowbar, and fill them with water time after time, follow with liquid manure, and then close them with fresh soil. The fruit set and remained. He has since repeated the process, and had several bountiful crops of cherished fruit. The outlook in respect to soil drought and the water supply is in some districts a serious one, and the inconveniences and loss resulting may be far greater than from a blizzard in March.

As we are preparing for press, Mr. H. Harris sends a concise record of “A Week’s Weather in Sussex,” which is not lacking in variety. He refers to last week:—“Monday—fine, sunshine, cold winds. Tuesday—sharp frosts, heavy thunderstorms. Wednesday—vivid lightning, heavy rain. Thursday—hail, hurricane, deep snow. Friday—blizzard. Saturday—thaw and fog.” Truly, as he says, the month just closing has justified its character of “March many weathers.” At the moment of writing, the bright sun and soft wind suggest that four lines by “A. R.,” in the “Westminster Gazette,” are not inappropriate as a welcome to April:—

“Hail, gentle spring, fair comer hail!
Crown the bare trees with misty green,
And smother every hill and dale
In flowery sheen!”

DAFFODIL LAND—TRESKO.

THE streets and squares of London, and most of our large provincial towns, owe much of their cheerful aspect in early spring to the presence of the Daffodil, the Primrose, and the Violet. In the more open parts fountain, statue, and lamppost are bright with golden tones, and fragrant with the scent of Violets. It must be a boon to clerk and warehouseman, cooped for hours in close dark rooms, to be able to refresh the eye for a moment with glimpses of cheerful colour and fragrance, suggestive of the open air, green fields, budding hedgerows, and tuneful birds.

It is, however, a far greater treat to see these flowers at home. When our gardens are bare and flowerless, except for a few scattered clumps of Snowdrop and Crocus, the gardens of Lily-land are bright with glittering colour, and fragrant with the delicate, yet pungent, scent of the Narcissus. What one may fairly call the “Home of the Daffodil” is the archipelago of sunny isles and granite rocks known by poets as the Land of Lyonesse—the Isles of Scilly. During early April one may see the flowers at their best. Tons of them already are despatched weekly to London and the great towns. Notwithstanding the apparent advantages of climate in the South of France buyers prefer the Scilly flowers—they arrive fresher, and in better condition.

During the spring and summer, steamers ply twice, and at times thrice, a week between Penzance and St. Mary’s, the largest of the Scillies. The voyage, in fair weather, is done in less than four hours, the distance being thirty miles from Penzance, and about twenty from the Land’s End. The trip is worth taking if only to see the magnificent cliffs. As one steers out of the harbour there is a capital view of the town, with the masts of merchantmen cutting the terraces of buildings that climb the hill. To the left, or eastward, about two miles distant is St. Michael’s Mount, rising from the blue waters like a vision in stone. A score miles across the bay the Lizard dips, while westward is the Land’s End.

After about an hour’s steaming, passing by the way the beautiful Lamorran Cove and Porth Quorra we come abreast of the Land’s End, catch a glimpse of the Longships Light, and soon feel the roll of the huge Atlantic waves. If the reader be no better seaman than the writer, the feeling is quite sufficient, and notwithstanding the magnificence of tumultuous seas, one prefers a seat beneath the bridge, and a nearer view of the machinery. In a further two hours one catches sight of the first of the Scillies, St. Martin’s, distinguished by a tower with broad bands of white, known as the “Day Mark.”

The Daffodil has been a favourite flower in English gardens for centuries. Only two kinds, however, are known to grow wild in our fields—Shakespeare’s “that comes before the swallow dares,” the Pseudo-Narcissus, of which Wordsworth sings; and biflorus, found

in Devonshire. It belongs to an order of plants of which *Amaryllis* is a type. Lay open the flower with a sharp knife. If it be a Daffodil the six stamens are of equal length and in one series. They have insertion low down in the tube. In the true, or Poet's *Narcissus*, the tube is longer and narrower, while the stamens are divided into two sets of three each; one set appears near the mouth, the other is lower down in the tube.

Standing on the quay at St. Mary's one sees across the Strait, here over two miles across, a wooded island with a stately house on its summit. A small steam launch runs to and fro daily. On landing, our attention is arrested by a semi-tropical vegetation, the most conspicuous objects being *Agaves* in flower, a score feet high, tall Palm-like *Dracænas*, and New Zealand Flax. *Tresco*, though only four miles in circuit, has a variety of scenery, open moorland, grand cliffs, and sandy beaches. Deliciously quiet and beautiful the blue waves glide up, silver-fringed, to lap the dove-coloured sands. But it is not always so. At times the visitor is a prisoner for weeks together, and, were it not for the telegraph, one might as well be in mid-ocean. In Westminster Abbey there is a monument to Sir Cloudsley Shovel, who, returning from the capture of Gibraltar, was driven ashore at St. Mary's. The fleet was wrecked, and nearly all the homeward bound were lost. A few trees mark the spot where they were buried.

Presently the *Lyonnesse* winds its way towards the rough but substantial stone quay at St. Mary's. We are hauled up an extemporised ladder, and once again rejoice in stepping on terra-firma. An eminently prosperous and respectable race these *Scillians*, though grave and reticent. St. Mary's and the neighbouring Isles, in summer at least, are a delightful resort for the artist and the naturalist. It was here, it may be remembered, that Mr. Brett, R.A., painted some of his best pictures. There is a peculiarity in the light, owing probably to the abundance of watery vapour—sunshine, but no shadows. Whilst approaching St. Mary's one is struck with the beauty of the sea. The colour varies, of course, with the depth, the varying light, opal, emerald and purple—bluer than sheets of *Hyacinth*, stretching away along the woodland vistas; greener than the fresh sprung grass beneath the Apple trees, where the lambs are skipping; with now and again a path of molten gold leading up to the great Sun's centre, as if He had again walked its surface, leaving behind Him footprints on the sea.

Nearly a thousand years ago, we are told, the island of *Tresco* was the seat of a Benedictine abbey. Being far away from help, it suffered repeatedly at the hands of French and Spanish marauders. That pile of rusted cannon balls by the ruined abbey wall was exhumed during excavations from time to time. Queen Elizabeth, to avoid further complaints, gave the island to a Godolphin, strong enough to protect it. It was from a descendant that the late Lord-Proprietor, Augustus Smith, purchased *Tresco* and the neighbouring islands. The present proprietor, Colonel Dorrien-Smith is a nephew of Augustus.

It is chiefly at *Tresco* where the "Lilies" are grown. The Daffodil is a hardy plant, needing no protection except from the boisterous winds. This is afforded chiefly by evergreen hedges—*Euonymus*, *Veronica*, *Tamarisk*, and *Escallonia macrantha*. The latter is a shrub with stiff, glossy evergreen leaves and trusses of rosy, trumpet shaped flowers. The plant was introduced by the late Mr. Augustus Smith. It luxuriates in the mild, salt-seasoned air of the *Scillies*, and will make a fence from cuttings 4 feet in height in as many years. There is a fresh-water lake beneath the hill, and on the slopes the flowers are grown by acres, from the grand Empress, Emperor, Sir Watkin, Horsefieldi, to the tiny nanus and Angel's Tears. The soil is a smooth, brown, silky loam, largely mixed with sand. It is not only the *Narcissus* that is largely grown at St. Mary's and *Tresco*; there are others of the Lily tribe, besides acres of *Stocks* and *Wallflowers*, which are ready for market weeks before ours. Perhaps the brightest bit of colour is *Anemone fulgens*—a dazzling scarlet. One of the tribe, it may be remembered, clothes the hill sides of the Riviera.

One must say a word about the world-famed gardens, for there flourish all the year round Palms, Tree Ferns, *Dracænas*, *Agaves*, huge *Hydrangeas*, *Fuchsias*, and the handsome *Phormium tenax*, or New Zealand Flax. The gardens—a series of terraces, crossed transversely by paths and stone steps, are filled with rare flowers and shrubs. One enters, in response to a courteous invitation by the rock garden, and we are surprised (I am speaking of June now) by the masses of brilliant colours—*Mesembryanthemums* chiefly, from pure white, various shades of yellow, rose, scarlet, mauve, purple, and crimson. The flower evidently delights in bright sunlight and sea air; everywhere it is at home here in *Tresco*. Pieces of it flung aside alight on a stone wall, take root in a few days, and present a delightful bit of colour. One of a larger kind bears canary-coloured flowers, and rambles unchecked along the beach in dense masses.

Ferns are not very abundant at *Tresco* or St. Mary's. I noticed a few tufts of the Sea Spleenwort, *Asplenium marinum*, on the rocks by Cromwell's Castle, and a strong stool of *Osmunda regalis*. The Heather luxuriates, and is especially charming where sheltered.—HERGA.

LAWNS AND ALLIED SUBJECTS.

(Continued from page 215.)

SUPPOSING the lawn site, either for turfing or for seeds, to have been primarily levelled according to whatever slope or fall has been decided upon, and that a certain amount of consolidation of the soil by tramping or other means has been uniformly given to it, the finishing process by surface levelling is one requiring some little amount of skilful management. If this is done in tolerably small sections where turf is to be employed it will be conducive to a good finish, the object being to have the least amount of traffic possible on the prepared ground. With this end in view, light shutters made by nailing three or four boards together with cross laths (the flat side to be always down when using) with a few long, light planks will be found a satisfactory way to avoid undue tramping upon the soil. On a large scope of ground this may possibly be considered superfluous. I do not think so, even in fine weather, which of course should always be taken advantage of if possible. In any case, for a tennis or croquet ground I should insist upon their use. In theory the turf-beater and roller will reduce all to a smooth plane, but in practice they do not always prove to be so effective. Care must be taken to cut the turves of a uniform thickness, and not of unwieldy breadth or length, resulting probably in a waste of time and temper. Respecting size, much depends upon the texture of the turf; but 15 inches by 30 inches may be generally regarded as convenient for handling.

In all cases I have dealt with in the use of turf, it has been taken from some part of the demesne, a breadth of the most suitable being previously prepared by mowing, sweeping, and rolling; the despoiled place being sown as early as possible with grass seeds. This was, in fact, the condition at one place under which we were allowed to rob the pasture, and where the soil was found to be in good heart, a little hand tillage and sowing down with a clean quality of grass seeds enabled us to take a second or even a third crop of turf off the one spot, according to subsequent requirements. In the matter of turf *v.* seeds, if the former is of fine quality, there appears not much to choose between the two methods. I must confess to a predilection for the former, for a lawn thus made has apparently more variety, and, consequently, more character in it, and the finest types of grass seed mixtures never appear to be quite mixed enough in the way of variety to prevent a kind of sameness. But few may agree with me upon that point; one advantage with turf, however, will probably be admitted, always provided that it is of good quality—viz., that the grasses present are the survival of the fittest to the locality; whilst with seeds, some varieties may be present and in considerable bulk, not so well suited to the local conditions. With seeds, some study of the subject is necessary to obtain the best results. Several of our eminent seedsmen have so comprehensively and exhaustively gone into this matter, that the highest possible has been attained in this direction, and with a lucid explanation as regards soil, position, and substrata, their practical advice can be seldom equalled and never excelled.

In the matter of seed-sowing quick germination and unchecked growth are the desiderata, hence nothing is gained, and much may be lost, if sowing takes place prior to a spell of genial weather being reasonably expected. The middle of April in most situations will be early enough, when given a calm day, a dry surface, even distribution of the seeds, with a thorough rough raking over to cover them as much as possible, and one final rolling as a finish, under favourable growing conditions the lawn will quickly appear in its incipient stage. A single horse iron roller worked by four men, two at the shafts and two pushing, occasionally used afterwards is able by its greater breadth and weight to accomplish more and better work than several applications of the hand roller. In rolling the operation should be alternate, where the fall is not too great to prevent uphill work—thus rolling in the length one time, the next crossways—transversely. With seeds it is important that mowing should not occur before the delicate plants have time to develop a certain amount of character and robustness, any attempt to bring the lawn into a perfectly kept appearance too hastily being more or less detrimental to its future prospects. With the employment of turf this does not obtain therefore for tennis grounds which are required for almost immediate use the turfing method is preferable.

Compared with making new lawns the task of renovating old ones is simple, although no sparing of labour should entail to prevent its being efficient. A mistake not infrequently met with is that of making up certain sinkages which have taken place from time to time by the removal of trees, turfing over flower beds, alteration of walks, or other causes. The filling of these hollows with fresh soil tends to a spotty appearance by the more vigorous growth, which will, possibly, continue to be noticeable for years; and, generally, this patchwork performance is not commendable, especially in regard to the simplicity of lifting and relaying the turf, which according to circumstances may be done in sections spread over two or more seasons. By the simple action of lifting the turf all the coarser weeds disappear, and the

aëration of the soil by digging and pulverising brings new life to the grasses, with death to the moss owing its existence chiefly to an impervious bed upon which the turf rests. Assuming that no alteration of the existing level is necessary beyond making good those defects previously noticed, operations may commence by stripping a breadth of say 10 feet, and removing the whole of the turves taken from it completely off the ground and in proximity to where the work will be concluded, to be there unrolled to prevent bleaching if the work is likely to take some considerable time. This arrangement gives a fair field for operations, and the work will proceed smoothly and satisfactorily from start to finish.

Having a breadth of 10 feet cleared space running transversely from side to side of the plot, this should be prepared by forking over to a uniform depth, picking out all weed roots, and thoroughly pulverising the soil, bring all to a firm, smooth surface level. The application of a given quantity, by measure or weight, of an artificial manure to each section as the work proceeds, and well incorporating it with the surface soil, is worthy of consideration as a tonic apart from any after measures of top-dressing. Bonemeal is sometimes used, but after various trials my experience does not commend its use either as a top-dressing or sub-dressing for lawns, and farmyard manure is a thing to be avoided for our purpose. For the sub-dressing from 2 to 3 ozs. per square yard of a prepared guano, several kinds of which are in use for farm purposes, with the same quantity of superphosphate of lime applied to the lawn surface when turfed, will, although it is apparently buttering the bread on both sides, prove to be as practically inexpensive as it will be found to be satisfactory and efficient. To resume the operation of turf lifting and relaying, the turf lifted from No. 2 section will be at once laid as it is removed on to No. 1 section already prepared, the principle of the operation being similar to that of trenching a piece of ground, the first removed being held in reserve for the final process.—SYLVA.

(To be continued.)

"BLACKS" IN POTATOES.

THE condition of the "noble tuber" is often very unsatisfactory when placed on the table. The cooked article may be apparently all right to look at outside, but when dissected for cutting is found to contain dark stains, agglomerations of adhesive matter—hard, unsightly, and of a bad tasting nature. In some cases a dark, flesh-like substance surrounds a core extending inwards from the skin to various depths, and this has a very unpalatable, earthy flavour. The defects are present whether the Potatoes are baked or roasted, steamed or boiled, pared or unpared, so we may conclude that the fault is not in the cooking, but is either induced by procedure in cultivation or storing, for the "blacks" are almost, if not quite, confined to the late varieties. I have known such defects more than half a century, and, in my opinion, there has been no improvement, unless in shapeliness without quality, in Potatoes since the advent of the disease in 1844, when, as now, there were two forms of blacks—namely:

1, "Skin or cylinder-black." This commences at the skin of the Potato, and may be compared to a quill-like body that has grown around the tuber and then entered it at right angles. This outer ring of dark flesh has a very unpleasant flavour when cooked, and besides being discoloured is waxy in texture. I have examined many such tubers in the raw state under the impression that the evil was caused by the larvæ of insects, but have not been able to detect any animal in the affected parts. The early varieties appear free from the discolouration, at least the earliest lifted, and it appears to a small extent only in the second early sorts, but the defect becomes very decisive in the late varieties, especially those of the Magnum Bonum type.

The stains always extend straight into the tuber at right angles to the skin, and the substance about the quill-like centres mostly egg-shaped, smallest end outwards, chiefly exist at the heel end of the tuber. The individual "cylinder-black" accords with a miniature stab or puncture, around which the flesh has healed, internally forming a sort of skin corresponding to the wound, the dark waxy core thus formed seldom exceeding one-eighth inch in diameter, and rarely passing into the tuber more than an inch.

On appealing to several veteran growers, suggesting some kind of grub or worm as the destroying agent, the verdict has invariably been decisively in the negative. However, I am not so certain about that, for the presence of scorpion flies (*Panorpidæ*), and observing that the Potatoes were always the worst affected when grown in the hollows of a field, or badly drained soil and indifferently tilled land, rather tended to confirm the view of the injury being caused by some pest from without. It seems strange that the producing agent, if of an animal nature—and it certainly is not vegetable—cannot be detected, but this may be my misfortune in not hitting the right time for catching the enemy. If any correspondent can throw light on this (to me) mysterious infection by sending to the Editor tubers con-

taining any creature suspected of giving rise to evil, I shall be very much obliged.

I have striven to connect the infection with the thread from an "eye," which has gone blind at a very early stage, the thread dying in consequence, giving rise to the egg-like substance. The physiologist and chemist rather support this view, as there occurs the same thing at the heel string in modified degree. Every "eye" of the stem—the tuber is an underground stem—has its central axis springing from the interior of the tuber, and if we kill this by salting the tubers to make them keep late in the season and weigh well for market, we get the blacks in the flesh with a vengeance. There remains also to be considered the important point of the assimilation of the nutrient elements by the tops, and the consequent nature of the plastic material composing the underground stem or tuber, which is waxy, dark coloured, and unwholesome or mealy, white and nutritive according to the contained components and measure of their elaboration.

2. "Flesh-black." This may obtain in either the waxy or mealy Potato, pervading the tuber, and forming lumps here and there through the flesh. There is nothing in either case of an organic alien body to account for the effect. Of course the raw Potato may be diseased, and in cooking have "blacks;" but this has no relation to the present inquiry. In perfectly sound tubers which turn black when cooked there does not appear any micro-organism, but the tissue is more or less broken down in the cell-walls, especially in the soapy stamp of Potato.

Nowhere does the Potato grow so well as on the warp lands and alluvial soils, or the washings from the hills of higher land—all mixtures of many earths, largely commingled with dead animal and vegetable remains. These alluvial silts and warps, where left high and dry, or drainage is properly attended to, do not, as a rule, produce Potatoes affected by "blacks," and even fens have been so improved that they have greatly lost the property for which they were long famed in growing "black" cooking Potatoes. Moor land also produces splendid tubers.

Granting some local land improvements, still Potatoes as now grown are, taking them in the bulk, a sorry lot. The Up to Date varieties all lack the high qualities of the Ashleaf, Lapstone, and York Regents. Quality has given place to appearance in the raw, and to waxiness and "blacks" with a modicum of mealiness in the cooked article. Worse Potatoes were never known within the past fifty years than the present day varieties as grown and placed in the market. Let both raisers and growers see to this, for assuredly if the home grower will not supply an unimpeachable article the foreigner can.

"Blacks" enter the underground stems or tubers of Jerusalem Artichokes, and even the true roots as well as the tubers. What are they but a product of unsweetened soil, such as exists in the fens and low-lying lands of Great Britain and in the bogs of Ireland? High land now receives very little real tillage as compared with former times. Aëration by tillage and sweetening by the periodical use of lime, with keeping drains in order, are matters that are not, broadly speaking, pursued with the same energy as formerly. This neglect of the land is seen almost everywhere in the fields and felt in every household.

"Potatoes will not pay for growing," is the modern cry, "therefore let us cheapen the cost of production." As a result, the land is "chemically manured"—stewed with acids, muriatic and sulphuric, along with the bones of countless animals? Is it not the way to produce "blacks" in Potatoes? Why not see to the drainage of hollows, thorough aëration of the soil, and dressing with lime? Surely the land contains enough acids from the long course of cultivation without adding more, especially for this important crop. Potatoes can only be improved by withdrawing the excess acids from the soil. Let anyone try the simple process of draining wet land, tilling the soil deeply, and dressing occasionally with lime.

A farmer, who had long been in the habit of using muriate of potash and superphosphate of lime for Potatoes, went back to the procedure of half a century ago, but instead of using lime, as then, had recourse to basic slag, relying on well-made yard manure for potash, and on rape dust for nitrogen. The farm, notorious for its black and waxy Potatoes when the "acid" manures were used, became again, as in former times, as famous for its white and mealy Potatoes; and though an agent for the sale of "acid" fertilisers, he gives them a wide berth in his Potato fields.

The chemist made out an excess of sulphuric acid and chlorine in the black Potatoes, partly due to the slow decomposition of crop residues in the soil through the low percentage of lime, which was considered the only thing the land needed to set it right. This the farmer gave, also a steady supply of phosphate in the basic slag. Muriate, or rather chloride, of potash has the well-known character of causing Potatoes to produce waxy tubers, sulphate being more appropriate; but I am not at all convinced of the innocence of sulphuric acid, for even without the muriate the tubers boil "black," while with neither in the land on the same farm the Potatoes cook dry, white, and floury.—EXPERIMENTALIST.

ODONTOGLOSSUM CRISPUM PRINCESS CHRISTIAN.

No new Orchids receive a better welcome than do varieties of *Odontoglossum crispum* that are distinctly above average merit. It matters not how many there may be, the best are sure to find a host of admirers. Such was the case on Tuesday, March 22nd, when Mr. H. Ballantine, gardener to Baron Schröder, The Dell, Egham, staged at the Drill Hall Show of the Royal Horticultural Society, *Odontoglossum crispum* Princess Christian. It is one of the handsomest crispums that has been seen of late both in its excellent form and the chasteness of its colouration. A glance at the woodcut (fig. 57) will convey an idea of the form of the flower, of which the ground colour is pure white. The fimbriated petals have occasional large bright chocolate red spots, while the sepals are similarly blotched and spotted. The plant was in robust health, and carried a grand spike. A first-class certificate was awarded by the Orchid Committee.

DENDROBIUM PULCHELLUM.

I HAVE seen this pretty Dendrobe growing in a variety of ways, and, perhaps, in none is it more effective than in baskets when allowed to grow out over the sides, rooting through the rods into the compost. The habit of the plant is very dwarf, the small stem-like pseudo-bulbs lying almost prone, and seldom exceeding 4 inches or 5 inches in length, but so free flowering that when thoroughly ripened the plants appear to be just a mass of flower. These occur singly or at the most in twos from the nodes, and are a pretty rosy pink with a golden yellow centre to the lip, which is delicately fringed.

D. pulchellum, as it is known in gardens, is not a difficult species to cultivate, and may as to atmosphere and temperature be treated much the same as recommended for the deciduous group generally. But even less in the way of compost is needed; in fact if the compost is provided it cannot be utilised by the roots, and only decays and makes the other material about it close and sour. If baskets are used they should be filled to within an inch of the top rods with clean crocks; over these a layer of rough moss, and then the compost consisting equally of peat fibre, sphagnum, and finely broken crocks. In fixing the material keep the centre well up to avoid accumulation of moisture.

In planting pull the plants to pieces and reject any old or shrivelled bits, or at all events lay them on one side and make up the best first, using the worst to grow for stock purposes. If well planted in good material no further disturbance will be necessary for a few years beyond cutting away some of the older shrivelled stems, and pegging down the young ones to take their places. It may be noted here that this species breaks naturally from many of the upper nodes, and not only from the base—or principally—as in some other kinds. Each season a few more stems may be brought down, and induced to root between the rods into the drainage material or about the rods of the basket.

After basketing, the plants may be returned to the growing quarters, and this should be a hot and very moist house, the baskets containing the plants being suspended in a good clear light. Water should be plentifully provided both at the roots and in the atmosphere, and a light dewing with water from the syringe is very refreshing and helpful on bright sunny days at closing time. It produces, in fact, the brisk, buoyant atmosphere that all Dendrobies delight in during the growing season, and owing to the mist settling on the inside of the glass the full force of the sun's rays is broken, yet its stimulating and quickening effect is unchanged.

There are various other ways of growing this pretty Dendrobium, some cultivators preferring large cork blocks for it lightly dressed with sphagnum moss. In this way the plants do well if properly attended to as to moisture, while they may also be grown in pots or pans in the usual way. On Tree Fern stems, too, the plants have a pretty and natural effect, and the roughness peculiar to these suits the

roots admirably. Bare block treatment is not good enough for it, the stems not swelling up to their proper capacity, or producing a proper complement of flowers.

Growth is rapid under the conditions indicated, and by about August the young pseudo-bulbs are fully developed as to size. When quite finished and the terminal leaves formed, hang the plants in the Cattleya house, and gradually reduce the supply of water to the roots. After a few weeks the foliage will begin to lose colour and fall, when remove the plants to a still cooler but light position, such as the front stage of a vinery, where the fruit is hanging, in an ordinary greenhouse. After this, little or no water will be needed during the winter, and the plants will be quite safe in a house that does not fall below 45°. As long as the bulbs do not shrivel, they will take no harm; in fact, in very cold, dull weather, they may hang for weeks without any water at all.

Insects are fond of this plant, especially of the young growing shoots; thrips and red spider often putting in appearance. Fumigation and repeated spongings are necessary to remove these, and must be persisted in until all the insects are killed. As noted above,

FIG. 57.—ODONTOGLOSSUM CRISPUM PRINCESS CHRISTIAN.

D. pulchellum is the name under which this plant is best known in gardens, but as a matter of fact *D. pulchellum* is an unknown plant in this country. Many years ago a species was discovered in India, and named *D. pulchellum*, but probably it was never introduced to cultivation. This was about 1830, and a year or two after Messrs. Loddiges, then a flourishing and important nursery firm, introduced the present plant, and figured it under this name.

Since then many botanists have found fault with the name, and some ten or more years ago the plant was figured and described as *D. Loddigesi*; but so firm a hold has the old name taken, that it is still, and probably always will be, known as *D. pulchellum*. It is a native of the Island of Hainan, and probably also the mainland of China; but it does not seem to have been found in India. It has not, I think, been very frequently imported, though doubtless this is more from design than from any scarcity in its habitat.—H. R. R.

MUSCARI BOTRYOIDES ALBUM MAJOR.—It does not appear to be generally known that there are two varieties of the pretty white forms of the common Grape Hyacinth, *Muscari botryoides*. The major form is much to be preferred to the smaller one. The latter has short racemes, with small closely set flowers; the former has a raceme of considerably greater length, and larger individual flowers. It is a very desirable variety, and should be secured by growers of early bulbous flowers.—A. HARDIMAN.

CULTURE OF MARGUERITES.

FEW easily grown flowers have enjoyed such a pronounced popularity as the white Marguerite. A few years ago there was no lack of prophets who predicted that they would rapidly decline in public favour. Instead of such being the case, I am bold enough to assert that Marguerites were never more largely grown than they are at the present time. The truth about the matter seems to be that plants which may be so managed as to produce white flowers at any season of the year are not yet numerous enough to enable us to dispense with such comparatively common flowers as white Marguerites. They possess, moreover, a type of beauty which ordinary individuals do not easily become tired of, and are also extremely serviceable in supplying both cut flowers and pot plants.

For many years I have made a practice of inserting a number of cuttings in September. These are transferred to small pots some time during October, and kept in cold pits unless very severe frosts are experienced. By covering the glass with a double thickness of mats such plants are quite safe when not more than 12° of frost occur. During the last two winters I have kept a good stock in frames without having lost a plant. I arrange them thinly, and thus secure very sturdy growth. Some time during March I place the whole stock in their flowering pots, the stronger plants being transferred to pots 6 inches in diameter, and the weaker ones into 5-inch pots. Two parts loam or good garden soil to one of well-decayed manure (or that from a spent Mushroom bed), with a little sand and soot added, is the standard mixture. The soil is pressed into the pots very firmly, and after being kept somewhat close in a cold pit or frame for a few days, abundance of air is given on all favourable occasions.

A week after the operation of potting has been performed the points are removed from each shoot, and as growth advances the plants are being continually given more space, to cause them to maintain their sturdy habit of growth. This continual thinning out is of the utmost importance in the production of good plants, and although it is sometimes difficult to perform it just at the right time through want of space, the exercise of a little ingenuity will usually help one out of the difficulty. I have frequently placed some in a sheltered position in the open air and protected them with canvas rather than spoil the whole batch by overcrowding.

As soon as the roots have permeated the new soil I like to commence feeding, as this, like all other species of *Chrysanthemum*, is a gross feeder. Soot water applied two or three times weekly is an excellent stimulant to begin with. After a few weeks of this treatment one of the many good fertilisers now in the market should be applied as a top-dressing once a fortnight, and liquid manure from the drainings of stables or cow sheds, diluted with ten times its bulk of water, be given three times weekly. During bright weather in April and May I like to remove the lights from the pits or frames so as to leave the plants fully exposed during the greater part of the day.

Many cultivators do not seem to recognise the great value of syringing the plants, but I make a practice of doing so each afternoon if the weather is bright, and I am convinced that it helps greatly in maintaining healthy and vigorous growth, and also in warding off the attacks of leaf miners, caused by the deposition of eggs by the fly. At one time I used to dread the attacks of this destructive pest, but by resorting to remedial measures at an early stage I am now always able to successfully combat it. The plan I adopt is this: As soon as I notice a single maggot in any leaf I dissolve 2 ozs. of soft soap in a gallon of water, and add to it half a wineglass of petroleum, mix this thoroughly, and syringe upon the plants. This will destroy all eggs it touches, and will also make the leaves distasteful to the fly. Starved plants, which are grown in a dry atmosphere and receive insufficient quantities of water, quickly fall a prey to this destructive pest, and I have no hesitation in saying that during the month of May I could cause a weakly plant to become badly infested with maggot solely by negligence or bad culture.—PLANTSMAN.

CALCEOLARIAS FOR BEDDING.

THE usefulness of these plants for the embellishment of the flower garden during the summer months cannot be disputed, yet they have of late years fallen into somewhat bad repute. This, doubtless, is largely owing to many of the plants dying suddenly in the beds when they should be at their best, which necessitates planting a large number in the reserve garden for the purpose of filling up. A discussion on the causes of this failure, and the means of preventing it, would be of great value to many readers of the *Journal of Horticulture*, for the Calceolarias stand almost alone for distinctness of character and profusion of flowering until late in the summer.

One cause of failure may, I think, be attributed to coddling the young plants in the winter whilst under glass. Then, again, notwithstanding the fact that the plants will root more freely in a cool soil, the time for planting in the beds is often deferred till the end of May. By this time

the soil has become warm from the action of the sun, and is therefore prejudicial to the plants starting root action at once.

The second week in March, if the weather be favourable, or at the latest the end of the month, the plants should be lifted carefully, and replanted in a bed of moderately rich soil in rows 6 inches apart, the same distance being allowed in the rows. The beds can be made up in any old frame, or even a turf pit in the open, provided they can be sheltered from severe frosts and keen winds, which often prevail during March and April. Throughout this time no more covering should be accorded than is absolutely necessary. Early in May the position in the beds which they are to occupy should be decided, and after giving them a good dressing of rich cool farmyard manure (cow manure for preference) or trench and digging this in, the plants may be carefully lifted and replanted with as little delay as possible, and be well watered in should dry weather prevail. They should receive copious supplies of water, the early morning and the evening being the best time for supplying it. By following the lines here laid down we lose only a very small percentage of plants. Our soil is of a very light open nature, and I incline to the belief that a retentive soil suits the Calceolaria much better.—CALCEOLUS.

NOTES ON CURRENT TOPICS.

AZALEAS.

THE painstaking article on page 232 of your Journal has all my sympathy, and so have these beautiful useful flowers. They are sadly neglected, and thus improved varieties, although abundantly existing, have been rarely seen during the last ten years, and were little heeded five or ten years before that. The varieties then introduced have hardly become generally known in the declining taste for these flowers, and yet they are a distinct advance, and to a considerable extent on such older varieties enumerated by your contributor, who only names Deutsche Perle of the newer ones. Within my recollection Sigismund Rucker and John Gould Veitch presented a new departure some thirty years ago as being the first instances of flowers of good substance, with a bold white border with salmon and lilac centres.

Since then brighter tints with a white border have been added. The very brightest of them all, *Souvenir de Prince Napoleon*, rich cherry-red with a clear white border, is seldom seen, although supplied at the time by Messrs. Veitch. Varieties like *Madame de Grevé*, *Madame de Kerchove-Lippens*, as well as *Fanny Boyé*, are very distinct in another way, having a smaller but more intense yet substantial blotch heavily bordered with white and most attractive. I think *Madame Louise de Kerchove* of very great merit, as well as the rather paler *Princess Louise*, both bordered with white. Among dark selfs are *Argus*, *Louis Lubbers*, and the newer variety of immense size, *Memoire de L. Van Houtte*, quite a first-class variety. A great contrast to the latter is *Comte Charles de Kerchove de Denterghem*, with a remarkably rich variety of tints. Lastly, but not least, among coloured varieties is *Madame L. Van Houtte*, a highly superior variety, very large, tender carmine margined with white. It lasted five to six weeks in flower, and no collection should be without it. Of white varieties *Madame Marie Planchon* is excellent, semi-double, with undulated edge. *Baronne de Vriere* is very large. Many more might be named.

The mention made of these plants deserving a house to themselves is well justified; but a combination with other classes succeeding well under similar treatment would probably suit amateurs better. I will refer to them on a future occasion. Meanwhile, I cannot help thinking that the claims of such old favourites, with the supplement of newest varieties, should induce growers to show them at the Drill Hall during the next month or two, where many might see the best of them for the first time, and certainly the younger generation would. If Camellias are worth showing as they are, surely Azaleas have a claim. Even our Continental originators of these lovely plants might be called upon to show what advance has been made; and as their appearance at the Drill Hall is by no means unheard of, the present flowering season of Azaleas seems to furnish an appropriate opportunity.

LANE'S PRINCE ALBERT APPLE.

In some horticultural journals this Apple is referred to at this season as excellent either "for dessert or cooking." A test would dispel the idea. It seems surprising that it should be described as suitable for dessert. Certainly, if dished to be looked at only, as at the Drill Hall meeting recently, it may be suitable for dessert as "a thing of beauty," but as to flavour it is in tartness hardly beaten by Dumelow's Seedling "at this season."

In penning such statements as to the quality of dessert Apples writers must not overlook the fact that they may disappoint numerous readers, who would find out their mistake only after growing trees a few years. A similar and frequent mistake is made with regard to the early variety *Duchess of Oldenburg*, when recommended as an eating or dessert variety, whereas it is a suitable complement in the trio of sorts named by me which are as sour as a lemon, figuratively speaking, and only useful for cooking purposes.

I should describe as an early eating Apple the *Yellow Transparent* (syn. *Grand Sultan*), which is indeed surprisingly sweet when fully ripe and eaten from the tree in July and August. It is a pity *Beauty of Bath*, *Duchess of Gloucester*, and *James Grieve* cannot be classed with the last named. They are described usually as dessert Apples, to which their tartness does not entitle them, however bewitching their looks, which is the only claim they can advance.—H. H. R., *Forest Hill*.

WEATHER IN LONDON.—On Thursday last, and throughout almost the whole of Friday, a heavy gale passed over the metropolis, bringing with it considerable quantities of snow and rain. The wind during those two days and on Saturday morning was bitterly cold, and pedestrians had much discomfort to put up with. About midday on Saturday it turned rather milder, and rain commenced falling, continuing almost without intermission until Sunday night.

— **WEATHER IN THE NORTH.**—During the last seven days a bitterly cold wind from the N.E. has continued, and a good deal of snow has fallen, both in the northern and the south-eastern counties. Throughout there has been little sunshine. On the mornings of the 25th and the 26th there were between 3° and 4° of frost. Monday brought sleety showers in the morning; the afternoon was dull but fair. Snow fell intermittently on Tuesday morning, but it melted rapidly on the lower grounds.—B. D., *S. Perthshire*.

— **GARDENING APPOINTMENTS.**—Mr. George Ellwood, for the past three years foreman at Lockinge Park, Wantage, Berks, has been appointed head gardener at Enbridge Lodge, Newbury, Berks. Mr. G. Kent, who has resigned his position as head gardener to the Earl of Yarborough, Brocklesby Park, Lincolnshire, has been appointed head gardener to Lord Mount-Stephen, Brockett Hall, Hatfield, Herts, and enters upon his duties this week. Mr. James Wyatt, for many years head gardener to J. Perry, Esq., Bradenhurst, Caterham Valley, has been appointed in the same capacity to W. Oppenheimer, Esq., Riversdale, Thames Ditton.

— **PRIMROSES AND HEPATICAS.**—When “E.” refers to double Primroses as not being readily propagated from seed, does he mean hardy ones or Chinese Primroses? So far as these latter are concerned it is known that the named doubles do not seed at all; but the semi-doubles do fairly well when artificially fertilised. But I know of no corresponding strain of hardy semi-doubles that seed. All double hardy Primroses are quite devoid of fertile organs, these having in the doubling process been converted into petals. How seldom do we see these Primroses in gardens southwards or round London? The hardiest are the white, lilac, and sulphur; but good clumps of them are rarely seen in gardens now. Like Hepaticas, they suffer much from dry, hot seasons, or from cold, wet winters. Both dislike a hot, arid atmosphere, and a soil that becomes waterlogged in the winter. Both like a deep sandy loam in which is an admixture of peat, with a gently sloping border somewhat shaded, where the foliage keeps vigorous and green during the summer.—A. D.

— **SPRING FLOWERS.**—After a winter of Arctic severity, and when for many weeks the earth is held in the iron grip of frost, early spring flowers come as something new and fresh to remind us that the hard time is over. The first Primrose and the first Violet carry with them a charm peculiarly their own, and envied indeed is the happy youngster who scours the hedgerows and gathers the first bunch. This season the interest in these harbingers has been small, as we have had them with us more or less all the winter. We seem hardly to have been without outdoor flowers on account of the extreme mildness of the winter. Long after we might have expected frost and snow the autumn flowers were blooming brightly—the Chrysanthemums, Roses, Dahlias, Asters, and all the rest of them; and hardly were these over when what are usually called harbingers of the spring began to make known their presence. Violets have bloomed outdoors in my garden nearly all the winter, and early in January Primroses were flowering freely. The Snowdrop was not to be cajoled by appearances, and did not come much earlier than usual, though its reign was shorter than in previous seasons. Not only in gardens, but in the woodlands has it been so, and with the new year came the early spring flowers. On this account the first Primrose and Violet have not carried with them their usual interest, as it is difficult to say when the first came. The early beginning seems like being continued, as fruit trees are showing abundant blossom, and everyone is pushing forward with work in the garden. All will be well if Jack Frost kindly hold aloof.—G. [“Jack” has not obliged our correspondent, who penned his note some time before he had to dig his way through the snow; he says he will not be tempted to prophesy again—at least in March.]

— **THE ROYAL GARDENERS’ ORPHAN FUND.**—We are reminded that the annual festival dinner of this most deserving charity will take place on Wednesday, April 20th, at the Hotel Métropole, under the presidency of C. E. Keyser, Esq., of Aldermaston Court, Reading, and late of Stanmore. Mr. Keyser is so well known as a patron of horticulture that we hope there will be a large number of gardeners present to give Mr. Keyser a cordial reception.

— **NATIONAL VIOLA SOCIETY.**—The annual exhibition of this Society is to take place on July 2nd at the Crystal Palace on the same day that the National Rose Society will be holding its Metropolitan Show. In the schedule now before us a score of classes are particularised, amongst which may be observed those for small as well as large growers of Pansies and Violas. The Hon. Secretary of the Society is Mr. R. T. Dougall, 52, Pembroke Road, Walthamstow, from whom schedules of the show may be had, and also full particulars as to membership of the Society.

— **HESSLE GARDENERS’ SOCIETY.**—A meeting of the above Society was held on Tuesday, March 22nd, Mr. Geo. Picker in the chair. The essayist for the evening was Mr. J. Lambert, and the subject “Hardy Fruits.” The essayist dealt with his subject in a masterly manner, giving the cultivation of the different kinds of fruits. He also gave the most suitable varieties for market. A good discussion followed, and several questions were asked, all of them being answered in a satisfactory manner. Mr. J. T. Barker showed plants of *Cypripedium caudatum*, *C. villosum*, *C. v. giganteum*, and some *Dendrobium n. nobilis*. Mr. J. P. Leadbetter, Tranby Croft Gardens, showed Carnations and Violets in variety. A vote of thanks to the essayist terminated the meeting.—G. W. G.

— **COOKING POTATOES.**—The proof of the pudding or the Potato is in the eating, and there are some varieties of pleasing appearance which are well known as prizewinners at shows, that in quality are very much inferior to others less attractive in appearance. In the case of Potatoes judging must to a great extent be done by appearances, and therefore the good-looking Potato stands the best chance of winning a prize. There is also something to be said about the cooking itself, as tubers in the hands of one cook will invariably present a different appearance than when boiled by another. At many shows prizes are offered for the best dish of cooked Potatoes, and this class might be encouraged still further. In the first place it is the quality, not the appearance of the Potato that is brought into question, as they are judged by flavour; and secondly, it is an encouragement to housewives to mark the difference between well and badly cooked Potatoes. Anything that can be done to encourage the growth of the best eating varieties of Potatoes is a right step. A Potato to thousands is but a Potato, and varieties are a myth, yet they are not slow in knowing which are the good cooks, and these they are anxious to purchase. The varieties of Potatoes now in cultivation are so numerous that something in the direction of classification might be done for the benefit of growers, and in the event of this, the point of cooking qualities should be clearly set forth.—G.

— **THE NEEDED RAIN.**—It is usually esteemed bad form to look a gift horse in the mouth, but badly as we needed rain, we could have wished that what has recently fallen had come in a warmer and more acceptable condition than it did. Certainly the ground had, because of such an unusually dry winter, become very dry, and in many places it has moved on the surface like dust. But much worse have been the grave complaints heard in many directions of the shortness of the water supply, wells and other water sources having already given out. No wonder if in such case those dependant upon uncertain supplies of water have felt anxious as to their position later should the comparative absence of rain continue. Even as it is we have not had very much, for snow, even if the fall be heavy, yet gives but a very small body of water relatively, and the snowfall generally has been light. That surface soil has been moistened to the depth of a few inches is something, but it has left that soil extremely cold, and many who have sown small or half-tender seeds have had cause to wish they had exercised rather more patience. Such weather as we have recently experienced, accompanied by such low temperature, could hardly be otherwise than harmful in its effect on seeds of many descriptions, especially those just bursting into growth. In spite of the beautiful weather we have from time to time experienced since the opening of year, yet there has been ample evidence that summer is not yet for us, and a cold ordeal has inevitably to be passed through. We now badly need sun heat to warm the cold saturated surface soil, and then also to open and fertilise the fruit blossom. But beyond that we need April showers, warm and abundant, to enable us to face the coming summer heat, which we shall doubtless experience in due course.—A. D.

— **SHIRLEY GARDENERS' ASSOCIATION.**—The annual general meeting was held at the Parish Room, Shirley, Southampton, on Monday, the 21st inst., the President, Mr. W. F. G. Spranger, presiding over an average attendance of members. The report showed that twelve meetings had been held during the past year, 516 members attending, giving an average of forty-three. The attendance, it was felt, should average more with a membership of about 140. The accounts showed a balance of £3 odd in favour of the Association, and there is still a number of subscriptions unpaid. The President, Vice-Presidents, Treasurer, and Secretary were re-elected. Votes of thanks were accorded to the President and also to the horticultural and local Press. Some of the members and their friends afterwards gave a vocal and instrumental entertainment, which was much appreciated.

— **GROWING VIOLETS.**—The method of propagation recommended by Mr. G. Hart, on page 236, has doubtless been proved by him to be a good one, as he prefers it to raising fresh plants from cuttings. I gather from his remarks, however, that it is necessary to allow the old plants to remain in the frames till the middle of April before they are lifted, and here arises a difficulty. Where frame room can be spared for this purpose all is well, but my experience of growing Violets is that the urgent need of the frames for the raising of early vegetables, annuals, and so forth does away with any possibility of leaving the Violets in them till the middle of April. Frequently the plants have to be lifted from the frames on this account early in March, and finish their blooming under the protection of a wall. It appears to be a matter of circumstances whether your correspondent's method is preferable to propagation by cuttings or divisions.—V. T.

— **THIBAUDIA MACRANTHA.**—Although there is a large and varied collection of plants in the conservatories at the Birmingham Botanical Gardens, none that I saw there interested me so much as the hardwooded plant from the Himalayas above named. It is so rare that it is known to very few gardeners. The plant at Edgbaston, now in a 10-inch pot, is of bush form, and has thin or meagre leafage. Its habit is loose, and by no means of dense growth. Out of bloom it would bear an insignificant appearance, but in bloom, as I saw it the other day, it was singularly pleasing. The flowers are produced singly and in clusters from the old leafless wood. They are mitre shaped, having fine segments at the mouth and ribs on the tube. They are about $1\frac{1}{2}$ inch in length, are pendant, and reddish-white in colour or veined. Altogether when in bloom the plant is a charming one. It requires conservatory temperature, and may be propagated by inserting tops of half-ripe shoots in sand under a bell-glass in good heat.—A. D.

— **THE MILD WINTER AND A STRANGE INSECT AT TORQUAY.**—Mr. Alfred Chandler, F.R.Met.Soc., the Meteorological Observer for the borough of Torquay, sends us the following from the "Western Morning News":—Amongst horticulturists in South Devon curiosity has been excited in the appearance of an insect supposed to be new to the present generation of horticulturists, and the product of the past abnormally warm winter—the mildest, perhaps, for the last twenty-five or thirty years. It should be stated that the infestation was discovered on a Cedrus Deodara tree in the garden of Mr. Dundee Hooper, Ardvary, Torquay. There was some difficulty at the first in finding an insecticide which would effectively destroy these insects. A few degrees of frost or a cold wind seems, however, to destroy them immediately. In connection with the excessively mild winter now just passed, we have had here in Torquay, which I see has also occurred in other parts of Devon, the Blackberry (*Rubus vulgaris*) in bloom in January, and setting for fruit in February. The high mean temperature during October and November of 1897, and December, January, and February last, was quite phenomenal. The mean temperature of the five months was 48.2° , or 14.8° of accumulated heat above the average of twenty-two years' observations at Torquay. Specimens of the insects were sent to Miss Eleanor A. Ormerod, who said they belonged to the genus *Lachnus*, known as the Pine aphid, possibly *Lachnus pinicola*, an English species, only more than usually noticeable, consequent on the mild season. For preventive measures kerosine emulsion was pronounced the best of all. Specimens were also forwarded to the Board of Agriculture, and Mr. Charles Whitehead wrote:—"It is undoubtedly *Lachnus pini* from which your Deodars are suffering. It is unusual to find these aphides so active at this time of the year, but it is due to the mild abnormal season." W. F. H. Blandford, of the Entomological Society of London, wrote to Mr. Dundee Hooper:—"It is certainly an aphid, and has nothing whatever to do with the American blight, usually so called, of Apple trees, or with the San José scale, which has lately created a scare in Germany, and appears to be in a fair way to do so in this country."

— **BIRMINGHAM GARDENERS' ASSOCIATION.**—At a recent meeting of this Society, Mr. W. B. Latham presiding, a very interesting and comprehensive paper, illustrated with coloured plates, on the genus *Iris*, was read by Mr. James Deans. The essayist's familiarity with the cultivation and study of the *Iris* specially qualified him to deal with the subject in an entertaining and instructive manner. A hearty vote of thanks was unanimously passed to the essayist.

— **DODECATHEON HENDERSONI.**—A pretty "American Cow-slip," or "Shooting Star," bearing the above name, has been introduced from California within the last few years. It occurs in the Ukiah Valley, as I gather from a note in a contemporary. It is a charming little plant, with crimson or rose-purple flowers, with a yellow ring at the base. Like the other Shooting Stars, the petals are reflexed like those of the Cyclamen, and this adds much to the interest of the plant in the eyes of many. It is dwarfer than several of the genus, and here has only grown about 6 inches high.—S. ARNOTT.

— **MUSHROOMS IN RAILWAY TUNNELS.**—It may not be generally known that the cultivation of Mushrooms is carried out most successfully in a disused railway tunnel at Edinburgh, known as the Waterloo Tunnel. In the course of a discussion on the proposed new Brixton and City Electric Railway, with stations at Brixton Hill, Lorn Road, Kennington Oval, Kennington Cross, Lambeth, St. George's Circus, and London Bridge, the construction of which was sanctioned recently by a Committee of the House of Commons, it was stated incidentally by Mr. Littler, Q.C., that although there might be Mushroom companies springing up on all sides, it was hardly the business of a railway company to engage in the cultivation of the succulent fungus. At the same time the City and South London Company, who will work the new Brixton line, are open to offers for the use of their disused tunnel at London Bridge for that purpose, as the new tunnel under the Thames which is now in course of construction will be utilised for the conveyance of their passenger and other traffic to Merrie Islington.

— **LEAF VARIATION.**—The varying forms of leaves on the same plant always attract the attention of the curious. On the Mulberry and others some leaves will be quite entire; others are deeply lobed. In none of our text-books does there seem to be any explanation of this. From what we read in elementary works one might almost believe that the tree first formed the nerves of the leaves, as if a sort of skeleton frame, and then spread the green matter of the leaves over it. But it would seem that these veins are to support the leaf—that is to say, to give strength to it. If this be granted, the leaves will not make veins or ribs when it has no green blade that needs this strengthening. When, therefore, there is a low degree of vital energy, and not much leaf-blade material formed, there would be no need of these supporting ribs. May we not, therefore, say that it is from some local weakness in not producing material to warrant the production of leaf-blade that accounts for the absence of the ribs, and which then results necessarily in a lobe, where otherwise the leaf would be entire?—LESTER BERNSTEIN (in "Meehan's Monthly").

— **VASES OR CUPS FOR CUT FLOWERS.**—When inspecting the collections of cut Narcissi at the recent show held at the Botanical Gardens, Edgbaston, my attention was drawn to what appeared to be a very suitable kind of vessel for the arrangement of such flowers as Daffodils. It is an invention by the Rev. J. Jacob, Whitchurch, whose collection of these flowers was arranged in them, and evidently they proved most suitable for the purpose indicated. The vessel is cylindrical, made of tin, about 4 inches in depth, and less in diameter. Some were painted green, and the remainder a chocolate brown—the latter, however, being the more appropriate in contrast with the green foliage of the flowers. At about half an inch from the bottom of the interior of the vessel is soldered a wire ring to form the base for a holder, and which consists to two disks of tin perforated with at least a dozen holes for the reception of the stalks of the flowers and foliage, each hole being no larger than for allowing the ready insertion of the flower stems—the insertion being specially suitable for the purpose, or indeed for any other kind of flower with no larger stems. The two disks are attached to the ends of a hollow tubular standard, also composed of tin, and of sufficient length to reach from the top of the inside of the vase to the ring below, thus affording a ready means of inserting the flower stems through the pair of disks, and holding them in the required position. As the standard or holdfast is moveable and fits easily inside the vase, either end of the former can be used, top or bottom. A small portion of dried moss was placed amongst the stems of the flowers and foliage to hide the inside of the vase. Altogether the arrangement seemed to be perfect, and Mr. Jacob intends to have it patented.—W. G.

— **BEEES AND HEPATICAS.**—Your note to my observation regarding *Hepatica angulosa* major leads me to say that I have not observed bees frequenting the Hepaticas. At this season their attention is greatly given to the Scillas, Chionodoxas, Crocuses and Daffodils, with the white Arabis and purple Aubrietias.—A. HARDIMAN.

— **JERSEY GARDENERS.**—The tone of the annual report of the Society of Jersey Gardeners is most pleasing. The three shows that were held in 1897 were very successful, while the list of members increased materially. The balance-sheet shows a satisfactory condition of affairs. Three shows were arranged for this year, one of which was held on the 24th inst. The summer exhibition will be held on July 27th and 28th, the Chrysanthemum one on November 9th and 10th. The Hon. Secretary is Mr. J. M. Gibbs, Spring Bank, Valley des Vaux, Jersey.

— **SWEET PEAS.**—A row, whether long or short, of Sweet Peas is desirable in most gardens. Failing rows, several patches in a flower border will provide excellent material for cutting. Sweet Peas remain in a flowering condition for a long period providing they have good soil to grow in and have copious supplies of water at the roots in dry weather. A further aid to continued flowering is to pick off all the seed pods as soon as seen if the flowers are not closely cut. Named varieties in special colours are numerous, but a sowing of mixed varieties is serviceable for general purposes.—S.

— **MINT.**—In response to "H. S.'s" inquiry (page 239), respecting the manuring of Mint, I would remark that I experienced a similar result some two years ago. I applied a thick coating of manure, composed chiefly of vegetable refuse mixed with coal ashes in a fairly decayed condition, when, to my surprise, in the following summer the whole of the long established bed was destroyed, excepting round the edge where the manure was very thinly spread or not applied. I had never known or heard of a similar occurrence before, and I thought it possible that the dressing was not sufficiently decomposed.—W. G., *Birmingham*.

— **EARLY CAULIFLOWERS.**—Early Cauliflowers are much prized, hence most kitchen gardeners make an early sowing in pans or boxes under glass in February or early March, following with another sowing about the present time. The young seedlings, properly hardened and kept sturdy, should be pricked out in a frame on a slight hotbed, but they will do very well without bottom heat if placed in good soil with a layer of rotted manure beneath them. This assists them to make rapid growth, and provides something which the roots will tenaciously hold, which is most desirable when planting out finally. Good heads may be obtained in July from the latter sowing. Sutton's First Crop is a good variety.—E. D. S.

— **WOOD PULP FOR PAPER.**—The requirements of the paper trade, according to a paper read recently before the Society of Arts, are likely to become a great drain upon the forests of Scandinavia, the United States, and Canada. Judging, says a contemporary, from the present rate of increase, the quantity of wood required will, before long, assume enormous proportions. It was estimated a few years ago that in the United States of America alone 500,000,000 cubic feet of timber were consumed annually, representing the destruction of 100,000 acres of forest. It was also estimated that each day the "New York World" consumed timber equal to 7 acres of an average forest. The world's timber suitable for paper-making is not inexhaustible, and we may some day be in a position in regard to wood as this country was at the end of the last century in regard to the supplies of rags.

— **SWEET VIOLETS.**—As Violets are much in evidence along the London thoroughfares, writes a correspondent, the following incident may be of interest. I was in a chemist's shop when a coster girl entered with a large basket of Violets and set it on the floor. I bought a bunch, and then noticed the chemist's assistant pass a small glass phial to the girl, the contents of which she emptied into the basket. "Tricks of trade," said the chemist with a smile, while the merchant gave him a look of sly humour from under her hat. "What was that she bought?" I asked. "A penn'orth of wood violet," he replied. "Those French Violets don't smell. They rest on moist moss in the basket, and the moist moss absorbs the perfume. That penn'orth will sell the basket." Then he told me that a "penn'orth" of musk perfume was used to improve the selling quality of pots of Musk, and that he had had a hawker similarly ask: "A penn'orth of white rose, guv'nor." As I went away I figured to my mind an old lady bending over that basket in response to the merchant's observation: "Fresh, ma'am? Just smell for yourself."

CHARACTER UNDER CANVAS.

PHILOSOPHERS AND —.

THERE must be something soothing in the word "philosophy," judging by the way it is hugged and fondled. It presents itself as a sort of infant phenomenon, prepared at a moment's notice to be cast for any part, to the joy and pride of its affectionate parent. But as in the talented company of Mr. Vincent Crummies, the unhappy player whom fate always flung into the same piece as the phenomenon grew deadly tired of the association, so possibly in the band of players who appear before the delectable audiences at the Horticultural Theatre there may be one or two who are weary of so much "philosophy," and pine for plain common sense.

The worst of philosophy is its irresistible attraction for many excellent and worthy persons, who like plain work but cannot bring themselves to call it by a plain name. Thus, when I start out to tilt at "philosophy" I may be unjustly suspected of tilting at men for whom I have nothing but admiration and respect. The philosopher who at the core is a true, sensible, honest soul gets mixed up with the large and increasing number aping the same name, whose voices are getting noisier in the world every day, yet whose heads are either empty or inflated. The sooner we make up our minds to call plain things plain names—when we learn to modify art and content ourselves with craft, to let common sense be our guide instead of philosophy—the sooner we shall be in a position to say that we are sure of our company. A good craftsman is better than a bad artist; a sound gardener can give useful lessons to any philosopher.

Passing to character under canvas at gardening exhibitions. The man who, in the disappointment of a defeat, hurls a torrent of abuse at the judges, represents human nature let loose that is a little unreasonable and a little vulgar, but still something that can be reckoned with and, with tact, controlled. On the whole, I respect the much-maligned "bad loser" rather more than the good one. It will be a bad thing for Britain when her sons all learn to take a thrashing "philosophically." Parliamentary proceedings have been enlivened of late by a discussion—and this is where the dash comes in—on "scallywags," and it has been elicited that the species known under this interesting name is usually the best fighter. He breaks bounds, derides discipline, and goes on generally in a way not approved in polite military circles; but when a bit of hot work crops up there he is in the van, laying about him with gusto. So the Army loves its scallywags, although it chastens them. In the same way, perhaps, the broad-minded horticultural judge has a sneaking respect for the noisy exhibitor whom defeat in the Grape class excites to angry reflections on the practical knowledge of the gentlemen who have "plucked" him.

But the philosopher in the tent is a different animal. He is not exactly human nature, and the less human nature there is in a man the more difficult it is to know how to manage him. Occasionally he is genuine. When he expresses open satisfaction with the judging and resignation to his defeat he means it; but far more often the philosophic outpourings are a cloak to something else. He is one of those who hold with the cynic that language is given to conceal thoughts; to bottle up for the time being, and uncork when the judge is safely departed and unable to defend himself against the insinuated charges of incompetence and favouritism. This philosopher of the tented field knows how and when to strike; he chooses his time with patience, but when an open fight comes he gets behind the scallywag.

There is another philosopher to be fought shy of, and that is the exhibitor who gives disinterested advice and assistance to rivals. He, too, is genuine at times, and nothing is finer than to see good sportsmanship holding sway; would there were more of it. But not infrequently the kind adviser has a thought for himself. There is a true story, known only to a select few, of two neighbouring gardeners who were competing with others in a class for a collection of vegetables very early in the season. Just on the verge of setting up, one of the two discovered that he had a dish too many. What was to be left out? He had to decide on the spur of the moment, and he was not strong enough to rise to the occasion. Happily he had his friend beside him, and that noble individual, with a self-abnegation worthy of the highest admiration, philosophically consented to give a piece of impartial advice. Critically surveying the collection, he pounced on a dish of French Beans. Not know what to take out! Look at those wretched Beans, and think again! The unhappy exhibitor fell into the snare and threw out the dish. He would have thrown the philosopher somewhere if he had caught him after the award was made, for the kind adviser was first, and proudly boasted of the ingenious way in which he had induced his most dangerous rival to get rid of his strongest dish.

There is a gay and humorous philosopher in a certain district who is noted for his smiling cheerfulness under all variations of the judicial barometer. When it is at set fair he smiles, when it is at unsettled he smiles, when it is at stormy he smiles. He is popular with judges because he never abuses them, but on the contrary always expresses his perfect confidence in them. Like the heathen Chinese he is ever child-like and bland. He thinks confidence begets confidence. He uses very large name cards for all his exhibits, and he consistently attaches them to the worst specimens in the various dishes. Extract the huge pin which secures the card, remove the latter, and a disease patch or other blemish is laid bare. But the philosopher still smiles. He is caught for once, but he hopes for better luck next time—and another judge. As for the judge himself, he sighs for the scallywag.—W. PEA.

ROSE NOTES.

WHEN I wrote the recent article on pruning we were having spring-like weather, and a large number of growers were busy with the knife. Although our Roses were by no means forward, neither for the date nor exceptionally mild season, one was tempted to begin earlier than usual. But we soon had a taste of winter, and although we happily escaped storms and snow, it was enough to check the rapid pruning going on. On the 13th inst. we had 13° of frost (Fahr). It has been advocated that such late growers and bloomers as Baroness Rothschild and Merveille de Lyon should be pruned a week or two earlier than other Hybrid Perpetuals; but did anyone really observe that this early pruning caused a correspondingly early break? I have pruned half a dozen plants of each at an interval of three weeks, and, although they were side by side, failed to discover any material difference.

Having recently seen some young Roses under glass that were badly attacked by mildew, it occurred to me how much more prone some varieties are than others to this pest, whether in the open or under glass. I noted that Innocente Pirola, Edith Gifford, and Souvenir de Paul Neyron were most affected in the above instances. They are also our worst Roses in this respect outdoors. One can scarcely put the attack down to a feeble constitution, for Edith Gifford is a hardy and robust grower. Then how seldom we find mildew on the Manetti stock while the Dog Rose or common Briar is particularly liable to infestation. We do not find it (except in rare cases) on the Banksians, which, although very strong growers, are certainly much influenced by chills. As further proof that feeble or tender-growing Roses are not prone to this disease more than others, let us call to mind how badly Her Majesty, Margaret Dickson, Abel Carrière, and Madame Gabriel Luizet are affected; while we find Ulrich Brunner and Gloire Lyonnaise almost exempt.

I am looking forward to reports from various growers of the way Rose wood has come through the winter. Perhaps this is premature, for I remember that the end of March was very severe in 1893. At present my own wood is in grand condition, and I do not notice that Fortune's Yellow (the tenderest Rose we grow) has any injured wood. When reports are given upon the wood, which can scarcely be done thoroughly except when pruning, I hope all will give their locality, and if close to water or upon high ground. Such reports can be of no service otherwise.

Already the Hybrid Sweet Briars are pleasing. They are considerably more forward than the common variety, and make their presence known by the perfume of bursting buds before coming into leaf. They are quite hardy in this country, and would soon make an impenetrable hedge. I have the first set over a large arbour, and which can be completely covered this spring when tying down the ripened branches. If Lord Penzance could only impart the scented foliage to our miniature Polyanthus without additional strength in growth, what pretty and sweet-scented little pot plants they would make!

How grandly Roses in unheated houses are coming on; but unless we keep them back as far as possible, we shall suffer later on. There is such a vast difference in temperature in an unheated house. A clear day, even with a keen wind outside, soon raises the temperature to 60° or 70°, only to fall to almost freezing point should the night be cold. It is a mistake to hurry Roses in such a house. We also suffer much from mildew, and the damping of young leaves during a spell of dull weather. Even one row of pipes around the house would avoid this humid atmosphere, and tend to equalise the temperature. In a house some 60 feet long, 24 across, and 12 feet to the top of the span, I have seen some grand Rose blooms cut already, and this house only had one row of 4-inch pipes around it. There will soon be a fine crop if the temperature can be kept fairly uniform. Climbing Perle des Jardins, L'Idéal, Rubens, Catherine Mermet, Niphotos, and Maman Cochet were the best when I saw them, on the 11th of the present month.

The foliage of Roses deserves attention. Some of them are by no means bad foliage plants in themselves. Take Perle de Lyon for example. This has the deepest shaded bronzy purple leaves we can imagine, and although not of much value as a flower, is well worth growing for its foliage alone. Maman Cochet is exquisite under glass just now; far deeper in its salmon shades than from open air plants, and although its own foliage is good, when the flower is placed with the bronzy leaves of Perle de Lyon the effect is greatly heightened. I do not care for other foliage with flowers than Nature provides, and have often been looked upon with horror by the gentler sex when disapproving of the universal use of Maidenhair Fern. But this is a different matter, for do we not try to get perfume, size, form, and various other characteristics transmitted to those not possessing it?

A deep green foliage suits a white Rose, but the bronzy purple is almost ideal for apricot yellows and deep salmon flesh shades. What beautiful shades a young leaf of Duke of Connaught possesses. Then we have the deep green of the Rugosas—Roses, by the way, that I have never found affected by mildew.

No less than three times during the present season I have been asked for the "Yellow Provence" Rose. This is so frequently the case that I have looked up many old authorities; but, as I felt sure would be the result, without success. Do any of your readers know of it? or could they give any aid? I believe either the Persian Yellow or Harrisoni was meant in each case.

Rose pests will soon be very numerous, but need do no great harm under glass, if we will only bear in mind the value of taking prompt measures towards their destruction. Nor need these be of so drastic a character as is often used when the enemy has gained a firm hold. It is easy to kill the aphides, thrips, and red spider if we syringe freely from the first and use a mild insecticide. I am not promising total extermination, but an early check that will prevent the insects doing irreparable damage and save our plants from the need of powerful insecticides. It is such an obvious error to leave the foes alone until they have increased in the enormously rapid way they do that there should surely be no need for any reminder. And yet we find, year after year, plants so left as to become hopelessly crippled.—PRACTICE.

PEACHES AND NECTARINES.

IN the majority of gardens these luscious fruits are extensively cultivated, and it is essential that those in charge shall annually produce good crops. Unfortunately the best results are sometimes prejudiced by neglect of one or more of the several operations, and I have penned the following brief notes as reminders to my brother craftsmen, who have probably found to their cost, as I have, that with disbudding and other points procrastination is one of the worst of sins.

DISBUDDING.

Attend to this early, but it must be done carefully, commencing as soon as the shoots can be displaced with the finger, and following up day by day until only the shoots required for future bearing are retained. Leave one shoot at the base of the branches or last year's shoots now fruiting, and another on a level with or above the fruit; the latter not being required for extension must be stopped at a few joints of growth. In the case of trees not fully grown it will be necessary to leave shoots about 15 inches distance apart, calculating from the base of last year's growth, to form the bearing shoots of next year, the terminals being trained in full length as space permits. The leading growths must not be less than 12 to 15 inches apart. Close training is practised, with the result of weak crowded growths, not nearly so satisfactory in fruit as growths fully exposed to light and air.

THINNING THE FRUITS.

Directly the fruit is fairly set and those properly fertilised can be detected by their taking the lead in swelling, commence thinning. Remove the smallest first and those on the under or at the back of the trellis, beginning with the weakest parts of the tree, thinning proportionately more than on stronger wood, which will tend to the equalisation of the vigour of the tree. The fruit ought not ultimately to be left closer than one to every square foot of trellis covered with growth, in order to have fine specimens of the large-fruited varieties; but the medium-sized kinds, such as Early Louise, Hale's Early, and Stirling Castle Peaches, with Early Rivers Nectarine—indeed, Nectarines generally—may have one to every 9 inches square of trellis covered by the trees; even the small varieties are the better for the latter mentioned amount of space, especially on weakly trees. The first thinning must commence not later than when the fruit is the size of horse beans, the second when the size of marbles, and again when the fruit is the size of Walnuts, leaving very few indeed over the proposed crop, though there must always be a margin for casualties.

SYRINGING.

Syringe all trees not in flower, but having the leaves advanced in formation, twice a day when the weather is bright, so as to keep them free of red spider. Attend to the afternoon syringing at closing time, or sufficiently early to have the foliage nearly or quite dry before night. Vigorous trees with sappy growths and large leaves require less syringing than trees with sturdy well-formed growth and stout textured leaves, the strong growth perspiring considerably at night, moisture often hanging on the leaves in the morning, whilst the foliage of the adjoining sturdy growing tree is dry. If the trees have water hanging from the points or edges of the leaves in the morning, omit the afternoon syringing, and on dull days damp the path and border instead of syringing the trees.

TYING-IN THE SHOOTS.

When the growths are sufficiently advanced tie them carefully to the trellis, not bringing the shoots into place too sharply. In securing the shoots to the trellis take care to leave sufficient space in the ties, for too tight tying, abrasions of the bark, and similar injuries, are prolific of gumming, and too tight tying otherwise causes an indent which renders the shoot liable to breakage at that point.—PRACTITIONER.

THE SCIENCE AND PRACTICE OF FORMING FRUIT TREES.

RESULTS OF PRUNING AND NON-PRUNING AFTER PLANTING.

THE non-pruning of a tree (P) at planting is shown in fig. 58. All the growths were left entire during the first season. Having a good root system on the dwarfing stock, and not of unduly vigorous development previously, such a tree will push most, if not all, of the buds from the extremities of the shoots to the base. The growths will be strongest at the top, weakening to the base. The leading growth (f) will be the most vigorous, the short and weak (g) stubbier or spur-like. Some buds, however, will remain dormant, as represented in Q at h, and the shoots on that part (R) will be wood buds (i). The roots will correspond with the parts above ground—namely, plentiful and fibrous (j).

Under favouring circumstances blossom buds will form the first season, particularly if of an early bearing variety, so that fruit may be had, if desired, in the second season, as indicated in the tree (S) at k. This

growth as outlined, while at its base also are smaller buds (s), these also pushing and producing stubby shoots or spurs.

The tree practically, under these circumstances, is on a level with that figured at 1 (page 263, last week), but a year older, meaning a year lost. The roots have also become similar; but those corresponding with free growth are stronger, as shown at t. The roots (u) in the mulching are adventitious and possess cuticular cells, imbibing nutriment fast enough without the aid of root hairs, and are relatively smooth, as shown at w.

There can be no question of the moderately shortened tree being the more profitable, but why a freely grown young tree should not be pruned the first year I could never understand. The non-shortening of short branches answers very well, because the root power may be strong enough to force free growths from them; but the shortened roots of the tree dug from a nursery are unable to produce free growths from the long strong branches. It is for that reason the branches are cut back, and then free growth follows, instead of premature fruiting and a stunted tree.

Endeavour has been made to point out the advantages or the reverse

FIG. 58.—RESULTS OF PRUNING AND NON-PRUNING YOUNG TREES AFTER PLANTING.

References.—P, Unpruned tree in leaf during the season following planting; f, long and strong unshortened shoots; g, growths from weak shoots of the previous season. Q, basal part of long and strong shoot, showing stubby growth; h, dormant buds. R, basal part of two-years branch; i, wood buds; j, root formation of tree. S, tree in the second season, showing—on one side results of non-pruning—k, fruit; l, fibrous root formation; m, feeding root in mulching. T, point of rootlet magnified, showing (n) root hairs. Opposite side, the result of shortening two-years branches at the marks under k closely: o, extension shoots in leaf; p, similar leafless, and marked for pruning; q, spurs. U, blossom bud of Apple; r, wood buds at base. V, terminal wood bud; s, small wood buds giving rise to spurs; t, root formation corresponding with strong wood growth; u, adventitious rootlet in mulch. W, rootlet magnified.

implies a stunted tree, though the roots will be fibrous (l), some of them pushing into the mulching (m). Such roots, if carefully lifted and examined with a lens, will be seen to have root hairs (n) for abstracting nutrition and transmitting it to the leaves and fruit. The check of lifting and the retention of all the growths have induced this precocious habit (k). All sudden checks and impaired reciprocity between roots and branches conduce to what we are pleased to call fruitfulness, but in reality a struggle for existence under threatened conditions of extinction.

But the wise cultivator does not want to laden his trees with fruit so early, as he knows there cannot be any real progress towards a profitable occupation of the space without growth on a more liberal scale. To insure this the four long and strong shoots are cut back as indicated by the bars below k, and in result we get free growth from each cut-back branch (o) in leaf, (p) leafless, while there are spurs at q. Some of these may probably have a blossom bud (U) relatively plump and round, and always with small buds at the base (r), which will develop into either spurs or shoots as the forces of the tree determine; or, the stubby shoots may be terminated by a wood bud (v), this in due course pushing a

of the systems most commonly in vogue in shaping trees for the natural or standard bush form. Young branches must be shortened to produce more and stronger, on the same principle that a maiden tree, with its solitary branch, is cut back to form a bush. When sufficient branches are formed to produce an open bush or head, the less of shortening the greater the production of natural spurs. With ample space every branch then becomes a cordon to be roped with fruit from base to extremity, and each should be strong enough to bear its load.—G. ABBEY.

A PLETHORA OF GARDENERS.

SOME articles have recently appeared in the Journal relative to the present outlook in the gardener's career. Without undue criticism I should like to touch upon some of the remarks which have been made by different correspondents. My observations will be solely confined to the position of gardeners in private establishments. There is no question

but that the outlook is a serious one, and requires remedial measures, which should rest with the gardening community to afford.

Young men commence their gardening career in one of the large establishments in the country, and pass from one noted place to another as journeymen. They have, many of them, a lofty ideal before them; they are enthusiastic. They "love to linger and survey the promised joy's of life's unmeasured way." They have cultivated their minds as much as the leisure and circumstances would permit; and for this purpose have read and studied current gardening literature, also some scientific works bearing on their vocation, while they have not neglected the works of the great masters in English literature. By these means the worthy aspirants have insensibly acquired refinement of mind and manners, added to proficiency in their business; but alas! with all these, and good moral conduct, they find themselves at the period when they hoped to obtain the position they have long desired, and for which they have worked, beyond their grasp. Thus, like the wise king of Israel, they find "the race is not to the swift, nor the battle to the strong," but that everything comes by time and chance.

The thought has occurred to me more than once, and I must confess has been forced upon me by many vicissitudes and changes, that the present system of manufacturing gardeners is the potent evil with which we shall have inevitably to cope in the near future. Have we not men distinguished in horticulture to whom the young aspirant looks up to with awe and wonder? Could not these men who have established horticultural societies form a committee who would assist journeymen and foremen in procuring situations? The present system seems to me to be very unsatisfactory. Young men have passed through gardens of considerable note where a large and continuous supply of fruit, flowers, and vegetables are demanded throughout the year, and where floral decorations are extensively done with much style and taste. They may have been foremen in one or two similar establishments, yet from force of circumstances over which they have no control are obliged to enter a nursery where they may be offered some half kept or small place where there is no demand for anything in particular. If they accept such places, the knowledge they have been at so much trouble to acquire is of little value. If it were possible for a committee composed of men who have had long experience as gardeners in good establishments, and who have perhaps vacated their situations, they would be able from their knowledge to select and recommend only such men as are qualified by former experience for the particular place in hand. Thus, perhaps, might be avoided the anomaly of men from large places going into small ones, and men sent into positions for which their former experience does not qualify them.

It would possibly be well if men should not be considered eligible to take a foreman's place in a really good garden without having first obtained a certificate of proficiency, not exactly in scientific attainments, but in practical knowledge. This would debar some of those whose leisure is spent in the public house, or in the study of the sporting papers; or whose winter evenings are passed at the card-table instead of acquiring mental improvement. To enter into such a scheme as I have endeavoured to point out, it would be necessary that funds should be raised for the purpose for supporting such a society or committee, but considering the vast community of young gardeners it would benefit, this ought not to be a serious difficulty.—F. STREET.

NOTES FROM WESTON HOUSE.

It is not my intention to notice in the present instance either the mansion or the delightful scenery by which Weston House, one of the estates of the Earl of Camperdown, is surrounded. Suffice it to say that from the summit of the ridge on which the mansion stands, and from many parts of the delightful grounds and well-timbered park, may be obtained extensive and picturesque views over a vast area of the fair county of Warwickshire to the south, whilst to the north and north-east the eye wanders over a wide and extensive district of undulating land, interspersed here and there with rich woodland scenery, the view in this direction terminating with the Malvern Hills.

Taking our route through the main entrance gates, we pass by the south front of the mansion, before which is an extensive flower garden laid out in geometrical designs with neatly clipped Box edgings. Many of these beds being of considerable size, large numbers of plants are annually utilised, the whole producing a charming effect from the terraces and windows of the mansion. To the right of this garden stands a magnificent *Araucaria imbricata* some 40 feet in height, and of great age and girth.

From the terrace gardens through a portion of the pleasure grounds, which are well studded with *Rhododendrons* (and choice *Coniferæ*, a *Wellingtonia gigantea* standing out boldly and forming a prominent feature in this part of the grounds) we reach an avenue of *Limes*, the turf beneath being covered with *Snowdrops*, *Daffodils*, and *Aconites*, which have a charming effect. I may mention that this part of the pleasure grounds is not mown except twice or thrice annually with scythes. This is in keeping with the beauty of the surroundings, and forms a fine contrast to the well-kept and closely mown terrace gardens adjacent thereto.

The kitchen garden comprises about 5 acres within the walls, which are 12 feet in height, and clothed with a collection of clean, healthy, and well-trained fruit trees. At the time of my visit dozens of trees of *Apricots*, *Peaches*, and *Nectarines* were a mass of bloom, and they gave every promise of a grand set of fruit, being well protected from spring frosts and keen winds by curtains of *frigi domo*, which are easily drawn when required, they being fitted with rings, which run along iron rods at the top of the wall. Large numbers of beautifully trained pyramid trees

of *Apples*, *Pears*, and *Plums* are dispersed over the garden. These all look in the best of health, and show evidence of a master hand. One quarter in this garden is devoted to bush fruits, as *Currants*, *Raspberries*, and *Gooseberries*, the latter being trained as pyramids, and which I am informed do remarkably well. They certainly looked far preferable to the low bushes so common in gardens, though I was pleased to see that the cordon system of cultivating this luscious fruit is obtaining favour with the gardener, Mr. Masterson, he having recently planted a long trellis of strong young trees.

The other quarters of the kitchen garden are devoted to *Strawberries*, *Asparagus*, *Onions*, *Celery*, *Peas*, and the many vegetables which are indispensable in a large establishment. I noted on the south border a long stretch of early *Peas* well through the soil, and looking in the best of health, being protected with branches of evergreens. On another border running north and south were some hundreds of *Carnations* grown for cutting purposes, and containing some of the newest and best of the older varieties.

The under-glass fruit department is equally well tended as the outside, the vineries being planted with such well-known varieties as *Hamburghs*, *Foster's Seedling*, *Muscats*, *Alicantes*, and *Lady Downe's*. The early house is well advanced, and carrying a good crop of well-formed bunches, the thinning of which has now commenced. In this house was noted a shelf of *Strawberries* (*Keens' Seedling*), the fruit of which had commenced to colour. Successional plants were being introduced into the various houses as required. The principal varieties grown are *Royal Sovereign*, *Vicomtesse H. de Thury*, and *Sir Joseph Paxton*. Then there are large quantities of bedding plants, and some well-grown *Cyclamens*, carrying large numbers of well-developed flowers, the colours being varied and beautiful. The Melon pits are at present utilised for propagating purposes, to be planted with *Melons* and *Cucumbers* shortly. The Peach house, which is span-roofed, contains some half dozen trees, well set with fruit.

The stoves, two in number, were originally vineries, for which they are better adapted than for plant houses. However, they are well furnished with climbers on the roof, which are found invaluable for cutting purposes. These comprise *Allamandas*, *Bougainvilleas*, *Clerodendron*, *Stephanotis*, and *Euphorbias*, whilst beneath these such plants are cultivated as *Gardenias*, *Pancratiums*, *Bananas*, and *Ferns*. They do not appear to resent the partial shade afforded by the climbers. Orchids are not grown to any great extent, though I noticed a few plants of *Cœlogyne flaccida* in bloom suspended from the roof, also fine specimens of *Dendrobium nobile* and *D. densiflorum*.

The number of heated pits and frames is considerable, and the majority of plants grown in them are such as are found most serviceable for supplying large quantities of cut flowers and for house and conservatory decoration. Several are occupied with *Violets* of the *Marie Louise* type, whilst in others are about 300 splendid plants of the newest *Chrysanthemums* on the large bloom system, and about 500 in bush form. Large clumps of *Lily of the Valley* are annually lifted from the open, and these, being forced in successionally, produce hundreds of spikes, which, when cut and bunched up with their own fresh green foliage, are much appreciated.

Much more might with justice be said concerning the features of these gardens, which have been under the management of Mr. John Masterson for over twenty years, and reflect great credit on his skill and assiduous care. I take this opportunity of briefly thanking him for his genial kindness to us on the occasion of our visit.

The conservatory, situated near the mansion, is a lofty well built structure, the roof of which is clothed with various magnificent climbers, including *Tacsonias*, *Fuchsias*, *Cobœa scandens*, and *Rhynchospermum*, while in the dome are rambling the beautiful *Lamarque* and *Devoniensis* *Roses*, giving indication of supplying in the near future thousands of blooms. On the centre bed some fine pyramidal-trained *Camellias* were in bloom, and interspersed between these are towering immense *Palms* and *Tree Ferns*. The back north wall is also well covered with *Camellias*, whilst round each side are arranged well flowered plants of *Cinerarias*, *Primulas*, *Cyclamen*, *Azaleas*, *Celsias*, *Callas*, and a host of others so indispensable for the embellishment of such a house.—VISITOR.

THE WEATHER AND FRUIT PROSPECTS.

THE weather during the past week has been of a variable and wintery character. The early part was fine and dry, with cold frosty nights, but on the 24th a bitterly cold north-easterly wind set in, which increased to a gale, accompanied by blinding showers of snow and hailstones. The snow drifted a good deal in places. The average depth was about 6 inches, but soon melted and percolated into the soil, which was dry and parched. The day temperature did not rise much above the freezing point. The two following days—25th and 26th—were of a similar character, with high and boisterous winds, doing some damage to trees and shrubs.

This cold wave has set in at an opportune time to check vegetation, which was getting in a forward state; but I fear *Apricots* in this neighbourhood will be a failure. *Peaches* and *Nectarines* on unprotected walls are in an advanced stage, but up to the present time they do not seem to have suffered much. A few *Plums* are in bloom, one tree of the *Grand Duke* on a north wall being in a very forward state. Owing to the late spell of arctic weather, *Pears*, *Apples*, and bush fruit seem to be a good deal retarded.

The lowest temperature registered during the month was 15° on the 7th inst.—G. R. ALLIS, *Old Warden Park, Biggleswade*.

A SUCCESSFUL YEAR AT WINCHESTER.

WE are glad to observe in the report of the Winchester Horticultural Society that as the result of the last Chrysanthemum show the balance in hand was raised from £55 15s. 9d. to £71 5s. 2d. The Society is admirably managed, and its autumn shows, though limited by the size of the Guildhall, rank as regards merit among the best in the kingdom. The executive committee, of which Mr. F. W. Flight is chairman, is composed mainly of professional and commercial gentlemen, but gardeners and nurserymen have each a representative. Mr. Chaloner Shenton is the Honorary Secretary.

NATIONAL CHRYSANTHEMUM SOCIETY.

FROM your report of the above Society's meeting it will be at once inferred that I had no confidence in Mr. Sanders' impartiality, and for that reason wished his removal from the chair. May I be permitted to say that the extreme opposite was my view of the matter? I called attention to the difficulties of his dual position, and to the fact that I believed the meeting had the greatest confidence in his absolute impartiality. The logical conclusion of this was that individually the decisions of the chair must be respected, and collectively they must be supported. I took this course in view of the pent-up feeling which seemed to exist, and could only do so under the cover of a motion—that of adjournment being the most convenient.—ROBT. FIFE.

[This is exactly what we apprehended on reading our reporter's "copy." We did not for a moment think the proposition a reflection on Mr. Sanders, whom we believe incapable of swerving from the line of right, and we cannot imagine anyone who knows him having a doubt as to his strict impartiality as Chairman of the N.C.S.]

THE "CARNOT MYSTERY."

AS a grower and exhibitor of Chrysanthemums, I should like to ask those who have had opportunities for comparing the various "Carnots" if they will kindly describe their colours as they have seen them.

I have only seen one of the so-called yellow varieties, and that under the name of G. J. Warren. The blooms which came under my notice have all been a very pale canary yellow. Mine are, or could be, described in the same words as used by Mr. H. J. Jones when describing Mrs. W. Mease.

Yellow Carnot or G. J. Warren are described as deep canary yellow. I am sorry to say I have not seen any of that colour yet, and would be glad if some of your correspondents would clear up what we might call the "Carnot mystery." Other growers are in the same fix as myself, and will not order Mrs. Mease, being, in fact, afraid to do so, in case the variety is not distinct enough to be placed on the same stand with G. J. Warren or Yellow Carnot. The Belfast dispute and Mr. Beckett's opinion of the flower staged as Primrose Carnot has something to do with the existing doubts; even Mr. Wells seems to have been in doubt, and when men like those mentioned are not sure, what about the rank and file of the growers? Therefore, in the interest of the latter class, I should be glad if a little explanation and instruction could be given in the *Journal of Horticulture*.

Will some disinterested growers describe, if possible, the different varieties of "Carnots," for we all dread disqualification when the critical moment comes? A case in point may be mentioned. I once staged Golden Queen of England and Emily Dale, when the latter was sent out as distinct, and being my first attempt to gain a prize, was very much annoyed on finding my card reversed, and the one word "disqualified" plainly written on it. That was a lesson never to be forgotten.

I enclose a circular by W. Wells; in it you will notice he places G. J. Warren and Yellow Carnot as identical, while he quotes Mr. Lees as praising the one and condemning the other. This all tends to mystification. I plead for enlightenment. I should be glad if some independent authorities could briefly describe the different "Carnot" sports for clearing up the mystery. I trust you may find room for the information requested, and which would be welcomed by many readers.—ALEX. HAGGART, *Moor Park, Ludlow*.

[We shall gladly find room for suitable communications on the perplexing subject.]

CHRYSANTHEMUM NOTES.

I NOTE this year a commendable practice is being adopted by many societies—viz., the early issue of the prize schedules. Both societies and exhibitors suffer when the schedules are sent out only a few days prior to a show. Especially to the smaller cultivator does this apply, for, as a rule, he confines himself to the strict requirements of his particular classes, want of space being the cause of this. Schedules issued in April or May admit then of no reasonable reconstruction of his forces in the matter of variety and number of plants.

So much interest is now taken in the cultivation of Chrysanthemums, that the class comprising the small grower and the amateur is distinctly on the increase, and their enthusiasm is unbounded. I have often been

surprised at the extent of the purchase of new varieties by the amateur. With this cultivator there is a distinct understanding that up to date they must be in the matter of variety.

The rate of progress in the quality and extent of the Japanese section of the Chrysanthemum is admittedly fast. If, however, some society would offer prizes for, say, two or three dozen varieties introduced previous to 1890, another series at a space of five years, and a third for up-to-date sorts, the real rate of progress and improvement could be accurately gauged. What is improvement in a Japanese Chrysanthemum is a disputable point, and one not universally acknowledged.

A brief reference to a few cultural points may not be unacceptable to the beginner. I note, too, a growing tendency amongst the experienced to treat the Chrysanthemum as hardily as possible. It is really a hardy plant, and any undue alteration cannot fail to be detrimental. To the inexperienced I would say, Root your cuttings under cool conditions, and grow them as sturdily as possible. Immediately the plants are well rooted get them into cold frames, where they cannot become weakened by undue heat, as is the case occasionally in the greenhouse or vinery. I need hardly emphasise the necessity of keeping the plants as near to the glass as possible in the early stages of growth, as it is common knowledge that without a stout foundation you cannot have a satisfactory superstructure. In the Japanese section especially is it imperative to secure robust leaves, and it is surprising what a difference is manifest in the manner in which the blooms, and the leaves also, remain fresh when cut as compared to those on weakly grown plants.

I am acquainted with cultivators who aim at reducing both the size of the wood and leaves. Especially does one instance of this occur to my mind. Calling on an enthusiastic beginner in August last year I remarked, "Your plants look nice, but I should have liked them better if they had been half as thick again." With a look of astonishment he replied, "Why, I have been trying to keep down robustness as much as possible." I said, "Well, results will prove the advisability or otherwise of such treatment." A very poor record of prizewinnings had my friend to show for his labour.

To the compost for the second potting I advise the addition of some directly stimulating food. For instance, I use Thomson's Vine manure, at the rate of 1½ lb. to every bushel of compost, for the reason that if the plants do not lay the foundation for a vigorous growth at the proper time, they do not thicken downwards afterwards in the right proportion. The attempt to accommodate too many plants is a common fault. Far better successfully manage fifty than spoil 100, is the maxim I would teach. Two other failings I have from time to time observed. One is, incorrectly supplying the plants with water; and the other, neglect in repotting at the proper time. In the first instance too much water is often given, causing a check to free root action, resulting in a loss of chlorophyll or colouring matter in the leaves. I have often been surprised to find how little water some varieties of Chrysanthemums will flourish upon. No plan will restore the lost colouring to the leaves as quickly as keeping the soil about the roots in a partially dry state after they decline in their natural colour. Stubborn cases may be remedied by the application of a pinch of sulphate of iron in the water, which ought to be applied in a tepid condition for a time.

Neglect in potting the plants in their early stages of growth means a loss of vigour by the continued cramping of the roots, which in itself cannot do otherwise than cause a check to that freedom of growth so desirable. Not only does it do this, but it is frequently the direct cause of a loss of many of the primary leaves at a time when we cannot afford to lose them. A check to the growth of Chrysanthemums in any form cannot be other than injurious to an extent not always appreciable at the moment.—E. MOLYNEUX.

ROYAL HORTICULTURAL SOCIETY.

MARCH 22ND.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair); Prof. A. H. Church, Mr. T. Hudson, Mr. Michael, Mr. A. Sutton, Dr. Müller, and Rev. Prof. G. Henslow, Hon. Sec.

Orchid Roots with Fungus.—With reference to the nature of the fungus attacking Orchid roots in a damp atmosphere, referred to at the last meeting, Dr. W. G. Smith of the Yorkshire College, Leeds, writes as follows:—"The Orchid aerial roots sent contained a fungus which lives on them and has killed some already. The absence of any form of reproductive organs renders it impossible to identify the parasite. Other portions of diseased plants (i.e., leaves) would be required to ascertain the true nature of the fungus. The fungus present attacks living cells, consumes the food laid up by the plant, and finally kills the roots. A disease having somewhat the same effects has been found in the Vanilla plants of Mauritius."

Palm Leaves Discoloured.—Mr. W. A. Holmes, F.R.H.S., of the Putney Nurseries, sent some portions of Palm leaves with numerous translucent spots. They were received from the Continent. An examination appeared to indicate a previous attack by insect grubs, but none were present, the interior tissue having disappeared from the spots; so that the new leaves would probably be quite healthy.

Vine-Browning.—Mr. Hudson showed a young shoot, the leaves of which were blistered and brown. This is due to the presence of the well-known myxomycetous fungus, *Plasmodiophora vitis*, allied to *P. Brassicae*, the "slime fungus," which gives rise to "club-disease," or "fingers and toes," in cultivated cruciferous plants. The only remedy is to cut away and burn all affected leaves or shoots. It is described and figured in Viala's *Maladies de la Vigne*, p. 400.

Ivy Sports.—Dr. Masters exhibited sprays of a peculiar small-leaved dwarf Ivy, remarkable for sending up vertical shoots with distichous leaves, though unattached to a wall. The habit appears to have become fixed, even in free-growing branches. On some shoots, however, the leaves were spirally arranged, as is usual on such branches. It may be observed that the change from the distichous arrangement of the leaves on the horizontal branches of the common Laurel to a spiral one, when the boughs grow erect, is common; but it is not a fixed character.

HARDY SHRUBS AND PLANTS IN TOWNS.

UNLIKE most if not all other departments in gardening, scarcely anything has been written about hardy plants and shrubs in towns. No one seems to have made them a special study. We have no authority to consult, but all has to be learned from actual experience, which is, of necessity, a slow process. I therefore propose to make reference to plants which have come under my own observation in a low, damp locality with a clay soil. Had they referred to a town situated in a high, rocky position, or in a light sandy or gravelly soil, the results would no doubt have been different.

It is not only the cold and smoke that act prejudicially on many plants, but excessive dampness causes not a few that grow well during the summer to succumb during the winter. Good drainage, the addition of opening material to the soil, and not planting too deeply, are the best methods to adopt with the object of reducing the losses to a minimum.

As might be expected, deciduous shrubs succeed better than evergreens. Amongst the former, the common Lilac always thrives well, and sometimes flowers freely. The Persian is not nearly so satisfactory. I could never make out why one is called the common Lilac (*Syringa vulgaris*), and the other the Persian (*S. persica*), seeing they are both natives of Persia. The so-called common one was brought to this country rather more than 300 years ago, and the Persian about forty years later.

The Gueldres Rose, sometimes called the Snowball Tree (*Viburnum Opulus*), and the Snowberry Tree (*Symphoricarpos racemosus*), both do well. The latter is a native of North America, the former of this country, and they both belong to the Woodbine family. The Dogwood (*Cornus sanguinea*) also flourishes. This plant is common in hedges and waste places in this country, also throughout Europe and North Africa. It is well known by its pretty smooth red branches and black berries. It received the name of Dogwood and Hound's Tree from the circumstance of a decoction of its bark having been used for washing mangy dogs. The Ribes or Flowering Currant, as it is usually called, answers fairly well.

Our old friend the common Elder of course grows vigorously. I wonder where it would not grow. There is one now growing in Chapel Yard, Hull. Once upon a time, those in authority connected with the chapel caused a large tree to be cut down below the surface of the ground, which was asphalted. The following spring growth from the stump lifted the asphalt, cast the fragments aside and proceeded quite comfortably to attain the former proportions. This process has been repeated from time to time for years, but still the Elder struggles on, although in a weakened condition. Good old Elder! The golden variety also grows well; but its leaves do not become nearly so yellow as when grown in purer air.

Roses do not flower at all satisfactorily, and in many parts they refuse to grow. The same may be said of nearly all Coniferous plants except *Thuia aurea*. This grows the best of any with which I am acquainted, but should not be planted in densely populated districts.

The Fig, which is so well known to gardeners, grows well in towns, especially when fastened to a wall. The Fig is believed to be a native of Western Asia, and was in early times introduced to the islands and countries on both sides of the Mediterranean and Southern Europe, where it has become indigenous. The Fig is so nearly the same in structure as our common Nettle that some botanists consider it belongs to the same tribe, for the following reasons. The Fig has leaves covered with very stiff short hairs, and with a pair of stipules at the base; so has a Nettle. It has flowers with stamens and pistils separated; so has a Nettle. Its flowers have no corolla, and the pistil is a little simple body which changes when ripe to a very small flat grain, all which are exactly what are found in the Nettle. In the essential parts of their structure the two parts are alike. There is, however, one important difference. The juice of the Nettle is watery, that of the Fig is milky. But someone may possibly say, Where are the flowers of the Fig? Cut a young Fig open and you will find the whole of the inside bristling with sterile and fertile flowers; the former have five stamens, and the latter a jagged calyx with a small white pistil sticking up in the midst of it.

Both the Greater and Lesser Periwinkle, *Vinca major* and *V. minor*, as they are called, prosper. There is nothing very particular to say about these glossy leaved creeping evergreens, which belong to the Dogbane family *Apocynaceae*. The Italians call this plant the Death Flower or Death's Violet. Some think it might have been intended for Sir William Fraser's death flower, when he was led to execution with a garland of Periwinkle, in mockery, placed upon his head. Sir William was the last destroyed of Wallace's adherents.

The *Aucuba japonica* has for some time been known as a good town shrub. Hollies and Laurels do not flourish in the district, and in very smoky places will not grow at all. The common yellow Broom grows and flowers fairly well for a time. The best way to succeed with it is, either sow seed or plant a few seedlings every year, so as to replace the four or five-year-old plants, which generally fail. *Euonymus japonicus* is rather tender, but when favoured by the shelter of a wall makes a charming shrub. Its glossy, dark green leaves, vigorous growth, and really handsome appearance will well repay anyone for the care bestowed upon it. The small English and the so-called large Irish Ivies are both useful; the latter as being far the more vigorous, soon covers the ground with a carpet of green, or a wall in the same way. It may also be trained in a pyramidal form, resembling a shrub when planted out, and is equally useful and ornamental, too, if grown in a large pot, tub, or box.

The king of all town shrubs is, I think, the Oval-leaved Privet. Given a fair amount of light, it will grow almost anywhere, either planted out or grown in tubs. It bears cutting well, even to the dimensions of a hedge, or a rounded shrub, and if left alone it will grow to the size of a small tree, but in this state it has a rather loose appearance. However, grown as a shrub, 6 or 8 feet high, it stands, in Hull, without a rival, and cannot be too strongly recommended, or too widely grown in towns. —A. E. PEAKE.—(Read at a meeting of the Hesse Gardeners' Mutual Improvement Society.)

(To be concluded.)

THE GEOGRAPHICAL DISTRIBUTION OF PLANTS IN RELATION TO WATERING.

How often do we hear and read that plants should not be watered until dry? This phrase has apparently different meanings with different individuals, as some go to one extreme and some to the other. Frequently we see plants in an unhealthy state, not because the temperature, ventilation, and soil are wrong, but because the watering is done in a rule of thumb manner instead of being based on scientific principles; and I am of opinion that if the rainfall of the quarter of the globe from which the plants were brought were imitated more generally, better plants and fewer failures would be known. And I propose in these notes to point out the broad principles of my text. As the capacity of the air for moisture increases with the temperature, it must follow, other things being favourable, that the amount of rainfall is greater in warm than in cold latitudes, and greater also in low-lying than in elevated districts. The amount of rainfall is greatest within the tropics, and decreases as we advance into higher latitudes. It is also greater at the sea level and moderate elevations than it is on lofty tablelands and mountains. In like manner more rain descends near the coast than in the central regions of a country. The ocean is the great source whence the atmosphere absorbs its aqueous vapours, which are eventually condensed in the form of rain.

The rainfall of the globe may be arranged under three great heads—the periodical of the tropics, the variable of the higher latitudes, and the abnormal of certain regions. The rainy season within the tropics is regulated by the monsoons, or periodical winds which blow in one direction for one half of the year, and in the contrary direction the other half. Beyond the tropics the rains no longer occur at stated periods, but become variable—that is, are distributed throughout the year in a very irregular manner. The mean annual rainfall of tropical countries is 200 inches, whilst the average annual rainfall of Britain is 36 inches.

Botanists have divided the globe into zones of vegetation. On each side of the equator, up to the tenth degree north latitude and the tenth degree south latitude, is the tropical region, within which there are two rainy and two dry seasons each year—a long rainy season of three or four months, and a short rainy season of about six weeks. Outside this zone, and extending to the thirtieth parallel of latitude, is the sub-tropical zone, in which the year is divided into a rainy and dry season, extending to six months of rains and six months of drought. This region is under the influence of the periodical winds or monsoons.

Before dealing with the average rainfall of different countries, it will perhaps be advisable to say that Palms are invariably found growing near rivers, watercourses, or on the seashore. Bamboos are mostly found in swampy places; *Nepenthes* inhabit swamps, as do *Utricularias* and *Sarracenias*. Orchids, whether terrestrial or epiphytal, are found mostly at elevations on the mountains of from 4000 to 6000 feet. Other epiphytal plants are *Eschynanthus*, *Pothos*, and most *Bromeliads*, and these should have a very free drainage to remove all surplus water.

India or the East Indies has its year divided into a very marked rainy and dry season, and plants from the plains or at moderate elevations require a long period of rest. On the west coast of India in the plains the average annual rainfall is from 78 to 100 inches, and at certain elevations on the mountains over 250 inches. The Neilgherry Hills have a temperate climate and moderate rainfall. The beautiful *Lilium neilgherrense* is found there. The rainfall of the Himalaya Mountains in Nepal and Sikkim at moderate elevations is 200 inches. The Khaysia Mountains have the largest annual rainfall on the globe; the average is from 500 to 600 feet, and as much as 30 inches has been registered in one day. This unparalleled amount is attributed to the abruptness of their slope, which faces the Bay of Bengal, from which they are divided by 200 miles of jheels and sunderbunds (being the deltas of the Ganges and Burrampooter). These mountains, from their insular position, are perennially humid.

The plants of the Indian plains include *Aristolochias*, *Beaumontia grandiflora*, *Cycas circinalis*, *Eranthemum pulchellum*, *Ficus elastica*, *Ipomoea Horsfalliae*, *Gloriosa superba*, *Hibiscus sinensis* and varieties,

Hoya bella, and some Ixoras, Jasminum Sambac fl.-pl., J. gracillimum, Plumbago rosea, Tabernæmontana coronaria, Linum trigynum, and Hedychiums. On the Sikkim Himalayas, at elevations of from 8000 to 14,000 feet, the Himalayan Rhododendrons are found as great trees. A cool temperature and great humidity of atmosphere is the requirements of this genus. This saturated state of the atmosphere in Sikkim is caused by the monsoon, which blows steadily from the ocean from May to October, and there is a current from the Gangetic delta during the remaining portion of the year.

The flora of the Khaysia Mountains is the richest in Asia, and includes Orchids, Palms, Bamboos, Balsams, and Scitamineæ. Amongst the Orchids are Vanda cœrulea, Dendrobium Farmeri, D. Dalhousianum, D. Devonianum, Cœlogyne cristata, Crypripedium insigne, Cymbidium eburneum, and Pleiones. Luculia gratissima is found in the valleys of Nepal below 5000 feet.

Taking into account the abnormal rainfall of the Khaysia Mountains, all plants from there should have water throughout the year and copious supplies during summer. Those from moderate elevations on the Neilgherry Hills and on the Himalayas below 6000 feet should have a period of rest extending over three or four months. The rainfall of Ceylon is from 60 to 80 inches, which falls during six months of the year, the remaining portion being dry. Cochin China has no distinct rainy or dry season, and the hygrometric readings are always high. Gardenias, Ixora coccinea, Clerodendron fragrans fl.-pl., Cycas revoluta, Musas, and some Nepenthes occur here. The Malay Peninsula has an average of 190 rainy days spread throughout the year, and an average of 100 to 130 inches of rain. Cyripedium barbatum is found on Mount Ophir. Burmah, on its coast, and the mountain slopes of Moulmein, have a rainy and dry season; the annual rainfall is 200 inches. Cyripedium villosum, Dendrobium formosum giganteum, D. infundibulum, D. Picardi, and Thunia Bensoniæ are found on the mountains of Moulmein.

Borneo has no marked rainy or dry periods. There is no day in which it rains incessantly, and no day in which there is not a shower. In Borneo are many fine Nepenthes. All tropical fruits luxuriate; Pines, Mangosteens, Guavas, Tamarinds, Pomegranates, and Musas. Hoya Imperialis is found here. Of Java the annual rainfall is 78 inches, and nearly one-half of this falls during the three months of December, January, and February; the remainder is distributed throughout the other portion of the year. Phalaenopsis amabilis, P. Schilleriana, and many Aeschynanthus are epiphytal on trees; whilst on the mountains, at elevations of 3000 feet, the original species from whence have sprung the Javanicum hybrid Rhododendrons are found. The Philippine Isles have their year divided into a rainy and dry season. The rainy season extends over 113 days, or four months; the average fall is 66 inches. Medinilla magnifica and Nepenthes Rafflesiana are natives of these islands.—F. STREET.

(To be concluded.)

LOROPETALUM CHINENSE.

THOUGH this early-flowering shrub has been in cultivation in this country for many years, it does not appear to be generally known or grown. It is very seldom one meets with it in gardens, notwithstanding the fact that it is very charming and distinct from other shrubs that are grown in similar positions. Messrs. J. Veitch & Sons, Ltd., the introducers of the plant, have shown it at the Drill Hall several times during the spring months, and it has always been much admired. *L. chinense* (fig. 59), possesses the merit of being quite hardy, and growing to a height of about 3 or 4 feet, produces its narrow petalled white flowers with the greatest profusion. It is a shrub to which more attention should be accorded, as it is very ornamental, and almost certain of extensive appreciation.

FIG. 59.—LOROPETALUM CHINENSE.

together with the prompt and satisfactory manner in which the claims were assessed and paid, have resulted in the operations of this Corporation becoming much better known and appreciated.

The directors are also pleased to draw attention to the fact that though the Corporation had only been established so short a time, the whole of the claims were paid without any further call on the shareholders being made.

Every possible effort has been made to inform the public of the special advantages and reduced premiums offered by this company, and the directors are gratified to be able to announce that the premium income this year is more than 50 per cent. over that of the preceding year.

The directors again desire to draw attention to the special advantage of insuring with this Corporation,—viz., that those insured can replace immediately their own glass broken by hail, the Corporation paying them at the rate per square foot at which the glass is insured. Another special advantage, and of which several insurers are availing themselves, is that of being able to cover wholly or partially the value of the contents of their glass houses by increased insurance of their glass—an advantage offered by no other insurance company.

Twenty-nine additional agents have been appointed during the year, making 101 in all—viz., ninety-five in the United Kingdom; five in the Channel Islands; and one in the Scilly Isles. All agents are paid by commission only. The directors invite applications from gentlemen who would undertake agencies in those districts not yet represented.

The Board of Directors meets not less than once in every three months, whilst a Committee of six of the Board meet as often as may be necessary to carry on the business of the Corporation. The total number of meetings held during the year has been twelve.

In accordance with clause 92 of the articles of association, no directors' fees have been paid.

[It appears from the financial statement that claims to the value of upwards of £1500 have been paid during the year.]

THE NURSERYMEN, MARKET GARDENERS' AND GENERAL HAILSTORM INSURANCE CORPORATION, LTD.

REPORT to be presented to the shareholders at the third ordinary general meeting to be held at Simpsons' Ltd., 101, Strand, London, W.C., on Thursday, the 31st day of March, 1898, at 3 o'clock, P.M.

The directors, in submitting to the shareholders their third annual report on the business of the Corporation for the year ending 23rd February, 1898, together with the audited accounts, have to state that no alteration in the amount of capital issued has taken place during the past year.

HAILSTORMS.—The hailstorms which occurred during the year 1897 will long be remembered for their extreme violence, for the large area over which they fell, and for the devastation and ruin which they wrought, more than eighty nurseries being very seriously damaged. On the 16th April, 1897, severe storms caused considerable damage to glass and crops at Luton, Dunstable, and Bedford, as well as in Lincolnshire, Cambridgeshire, and North Herts. On the 24th June, 1897, hailstorms of unprecedented violence occurred simultaneously in Essex, Hertfordshire, and Middlesex, the results being most disastrous at Chelmsford, Ingatestone, Ponder's End, Enfield Highway, Waltham Cross, Enfield, New Barnet, Heston, near Hounslow, and Harrow. The glass houses at over sixty nurseries were wrecked by these storms, and crops in several localities were completely destroyed. Many of the nurserymen, market

LONDON'S OPEN SPACES.

V.—HACKNEY MARSHES AND FINSBURY PARK.

OF northern and north-eastern open spaces, the largest, if in some senses the least beautiful, is Hackney Marshes, with its 335 acres of ditch-divided land. Subject to periodical inundations from the river Lea in the old days it was much frequented by fowling and hawking parties. In relation to this latter sport a curious story is told. In September, 1792, a hawk was caught at the Cape of Good Hope, and brought from there by an English vessel. The bird had on its neck a gold collar on which was engraved: "This goodlie hawke doth belong to his Most Excellent Majestie, James Kinge of England, A.D. 1610." The discovery created much discussion at the time, and it was recorded as a curious instance of the longevity and flying powers of the hawk, since the bird was believed to be one that "on the Lea marshes mounted so high with his game that both hawk and heron got out of sight and were never seen more. Inquiry was made, not only all over England, but in all the foreign princes' courts in Europe, the hawk having the king's jesses and marks sufficient whereby it might be known; but all inquiries proved insufficient." That the kings of England had long looked upon the Lea or Hackney Marshes as good sporting ground is shown also by an entry in the account of the Comptroller of the Wardrobe of King Edward I., 1299, "Paid to Will de Foxhunte for the keep of twelve hunds belonging to the king for his use on the Lee marshes, each dog per day a halfpenny—£9 3s."

The Marshes have also been the scenes of war and warlike preparations. It was here the Duke of Gloucester and his party appeared in arms in the reign of Richard II., and remained encamped while they sent John, Lord Lovel, with the Archbishop of York and others, to the king. It was during this sojourn on these then sodden and miasmatic flats that the duke contracted the ague, which, according to historians, so worried him. In the reign of Charles II. Hackney Marshes figured in a notable attempt to improve the ordnance of the time inaugurated by Prince Rupert. That fiery Royalist leader set up a water-mill, that gave him sufficient power to bore guns by a new method he had discovered, but the secret died with him, and the mill fell into ruins, which were still in existence at the beginning of this century.

Coming nearer to the present time we find the records of Hackney Marshes a mixture of accounts of floods, sporting events, and disorderly gatherings. In 1774 the remains of a great causeway of stone were discovered, with many Roman coins and pieces of pottery. It was probably one of the many great Roman highways, but though of intense interest to antiquarians the mob saw nothing in it but an excellent opportunity to make a little money, the stones being carted away and sold by the load, and the whole relic completely demolished. A good specimen of the sporting gatherings is afforded by one which took place on Thursday, August 13th, 1737, when a horse race was run, or rather swam, from Tyler's ferry to the bridge in Hackney Marsh, the competitors being two well-known sportsmen, and the first horse winning by two lengths. It is estimated by a writer of the time that 8000 persons gathered to see this contest. There is also the significant sentence that "upwards of 300 robberies were notified to the authorities as having taken place on that day." Hackney Marshes were also notorious for bull-baitings and prize fights.

Formerly Hackney Marshes were flooded to an extent unknown in late years, "St. James's Chronicle," of January 19th, 1841, describing a great flood of that year as being "like the sea," boats that ventured on it being upset, and many narrow escapes from drowning taking place. These things have all been bettered, the Marsh is properly drained, clumps of trees adorn it here and there, disorder is suppressed, the sports are cricket and football, and in the great stretch of land with its many quaint memories the County Council hold for the people one of the most valuable of our metropolitan "lungs."

Finsbury Park is another of London's great northern spaces, though why it should be called "Finsbury" nobody seems to know. It is a triangular space of land some 120 acres in extent, lying some miles from Finsbury proper, Islington, Hoxton, and Holloway intervening between it and the district after which it is named. The site was originally known as Hornsey Wood, which in 1774 was described as "a coppice of young trees, at the entrance to which is a public house to which great numbers of people resort from the City." This wood for some time shared with Chalk Farm the dubious honour of being a favourite meeting place for duellists, and at the tavern near by, "Hornsey Wood House," Mr. Reay and Mr. Lambton, two City magnates, drank coffee before they fought and killed each other. The tavern, which lay just beyond the "Sluice House," so celebrated for its eel pies in the last generation, became very popular. The grounds were laid out as tea gardens and a lake formed, the water being supplied by the New River, which runs near by. For a long time the grounds were devoted to pigeon shooting matches, but eventually the patrons of the sport found Hurlingham and the "Welsh Harp" more convenient, and "Hornsey Wood" was deserted by them. The spot was a favourite resort of the poet Crabbe when in London, and on one occasion, too tired to walk back to town, and not having sufficient money on him to pay for a lodging, he lay down on some hay in the coppice and passed the night there.

The Park, which is well laid out with ornamental walks and flower beds, was acquired by the Metropolitan Board of Works in 1866, at a cost of £142 per acre. It was opened by Sir T. Thwaites in 1869, and is now, under the control of the County Council, one of North London's most charming and popular resorts.

Another most important open space in North London is Clissold Park, a beautiful pleasure ground 53 acres in extent. It was purchased for

the public in 1887 by the Metropolitan Board of Works, the Charity Commissioners, and the local vestries, at a total cost of £86,000. Since it has been in the hands of the County Council it has been much improved, its flower beds being one of the sights of the district. The spot has no particular history, legend according it only the somewhat gruesome fame of being the place—or very near it—where the first gibbet was erected in England.—("Lloyd's News.")

SPRING SHOWS.

TORQUAY.—MARCH 23RD.

THE show held at Torquay adds yet another to the great successes which the local Gardeners' Association has achieved in this direction. The class for groups of miscellaneous plants was well filled, Mr. W. Satterby, gardener to Mrs. Rawson, taking first honours with a most attractive exhibit. Mr. W. H. Minifie, gardener to Mrs. Hassall, was a close second; Mr. C. R. Prowse, gardener to Dr. W. Ford Edgelow, and Mr. R. W. Hodder, gardener to Mrs. Trevor Barkley, being respectively third and fourth with displays very little behind the first in point of merit.

The Orchids shown by Mr. G. Lee, gardener to Miss Lavers, and the miscellaneous stand exhibited by Mr. W. Bale, gardener to J. Snelgrove, Esq., formed great attractions, as did the trade exhibits. Of these Messrs. R. Veitch & Sons, Exeter, contributed a large portion. The Committee had a specially constructed basin and fountains in the centre of the hall, and Mr. F. W. Meyer, of the above firm, had laid it out in the form of an artificial lake some 30 feet across. With the fountains playing and the whole illuminated with a unique arrangement of electric lights, as it was in the evening, a most charming effect was obtained, and great was the admiration expressed by the crowds of visitors. The other nurserymen exhibiting were Messrs. W. Allward, W. Burridge & Sons, Curtis, Sanford & Co., the South Devon Fruit Farm, Beachey & Co., and W. B. Smale, who showed a choice selection of Azaleas and Rhododendrons.

The table decorations were extremely good, Mr. F. Peacock, gardener to P. W. Bushby, Esq., being first with a light and tasteful arrangement of *Narcissus poeticus* and *Roses* W. Allen Richardson. Mr. J. Davis, gardener to Lady Macgregor, was a close second, with a lovely arrangement of Daffodils. The Cyclamens shown by Mr. R. W. Hodder were also noteworthy. The Corporation exhibited a stand of flowers from the open air, and Mr. C. H. Gerry some well grown Cinerarias. The arrangements were carried out by a hard-working Committee of gardeners, aided by Dr. R. Hamilton Ramsay (President), Mr. W. A. Masterman, and Mr. W. B. Smale, J.P. (Vice-Presidents), and Mr. Fred. C. Smale (Hon. Sec.). These all worked hard to secure success, which object was certainly attained, the attendance being extremely good throughout the day.

BRIGHTON AND SUSSEX.—MARCH 29TH AND 30TH.

THIS show was a decided improvement upon that of last year. Not because there were better exhibits, but on account of greater number and a good all-round competition. Mr. J. Hill, gardener to C. Wallis, Esq., Springfield, Withdeane, had a well-arranged group, which proved what a good effect can be gained by the simplest and easiest flowers and plants to grow. Mr. G. Miles, Dyke Road Nursery, followed very closely. Tables of plants were good, Mr. G. Miles being ahead, and having some exceptionally high-coloured *Begonia Gloire de Lorraine*. Mr. Bonson Lister, gardener to E. A. Wallis, Esq., ran this exhibit very close. Mr. Harper, gardener to E. A. Tucker, Esq., Vernon Place, Preston, was first for a collection of Orchids, *Lycaste Skinneri splendens*, *Sophronites coccinea* (very bright), and *Laelia harpophylla* being the best. Mr. H. Garnett, gardener to R. G. Fletcher, Esq., Mount Harry, Preston, also had an excellent stand.

One of the most pleasing exhibits was a class for a mantelpiece and hearth arranged with plants. In this instance, mirrors, and fire-places, were set in between screens, and the whole tastefully decorated by the Society. What good use can be made of our common Primrose was amply shown here by Mr. G. Miles, Dyke Road Nursery, who was ahead with a charmingly simple arrangement. Mr. E. Meachen, gardener to Mrs. Armstrong, Woodslee, Preston, followed very closely. Hyacinths and Tulips were good; Mr. J. House, gardener to Sir F. Mowatt, K.C.B., Withdeane Hall, winning for twelve Hyacinths, and Mr. E. Anderson, gardener to B. Parish, Esq., Preston Park Avenue, for a like number of Tulips. We have not seen Lily of the Valley so numerous here for many years, and they were exceptionally good; Mr. A. E. Golding, gardener to H. St. George Voules, Esq., Dyke Road, was only just ahead of Messrs. W. Miles & Co., Hove.

Lachenalias were largely shown, but all were the old *L. tricolor*. The pots from Mr. J. Turner, gardener to Sir Greville Smythe, Wick Hall, and Mr. J. Hill, gardener to C. Wallis, Esq., Withdeane, would have been hard to beat; so also would the grand pots of Mignonette from Mr. W. E. Anderson, gardener to B. Parish, Esq., Preston Park. Freesias, Violets, Primulas, Cinerarias, and Hydrangeas were good. The Spiræas were beyond the average, the twelve best pots coming from Mr. G. House, gardener to Sir F. Mowatt, K.C.B. Cyclamens were also very good, Mr. C. Murrell, gardener to Mrs. Jenkins, Burgess Hill, having a grand dozen. It was the same in a class for twelve Genista fragrans, the best coming from Mr. H. Head, The Drive Nursery, Brighton. There were some grand *Amaryllis* from Mr. G. House, some of the best we have seen. *Mollis Azaleas* from Messrs. W. Miles and Co., Hove, were also most noticeable, as were the six *Callas* from Mr. E. Anderson.

For twelve bunches of *Narcissus* there was strong and close competition, Mr. J. Harper, gardener to E. A. Tucker, Esq., Preston, winning with some very clean flowers, closely followed by Mr. M. Tourle and Mr. J. Hopkins. Some really good greenhouse and stove cut flowers came from Mr. H. Garnett, gardener to R. G. Fletcher, Esq. There were six boxes of twelve cut Roses, that from Mr. G. W. Piper, The Nurseries, Uckfield, being far in advance, and containing The Bride, Bridesmaid, Maman Cochet, Madame Willermoz, Jean Ducher, and Souvenir d'Elise Vardon as the best six. Mr. G. Miles, Dyke Road Nursery, followed. A stand of natural flowers for the dinner table was closely contested, Mr. E. Meachen just beating Mr. M. Tourle, The Gardens, Little Horsted. Groups of plants in the amateurs' section were good, first being awarded to J. R. Cattle, Esq., Dyke Road.

The most notable non-competitive exhibits, among a large number, were *Azaleas*, *Ericas*, and *Boronia megastigma* from Messrs. Balchin and Sons; a number of cut Roses from Mr. G. W. Piper, Uckfield (who had good examples of his new Tea Rose Sunrise; excellent fruit from Messrs. Cheal & Sons, Crawley; Ferns from Mr. W. Goodcliffe, Worthing; and hardwooded plants from Messrs. Cutbush & Sons, Highgate.

SOUTHAMPTON.—MARCH 29TH AND 30TH.

In the Victoria Hall, the Royal Southampton Horticultural Society held its spring show. We trust it will prove as successful financially as it was horticulturally, as the Society is sadly in need of funds to enable it to carry out its programme during the present year. The classes, though not numerous, were thoroughly representative of exhibits for the time of the year.

The centre of attraction was the group of Orchids arranged with Ferns and foliage plants, and which were effectively displayed in front of the orchestra. Mr. E. Carr, gardener to W. A. Gillett, Esq., Fair Oak Park, Bishopstoke, was an easy winner of the premier award with well-flowered plants. Mr. A. Pragnell, gardener to Captain Shaw Storey, Elm Lodge, Bursledon, was a creditable second. Mr. Carr also won the chief award for a miscellaneous collection of plants arranged for effect. Mr. W. Peel, gardener to Miss Todd, Sidford Lodge, Shirley, was second, and Mr. Wills, florist, Southampton, third.

Azaleas were a feature of the show, so well were they staged. Mr. Mitchell, gardener to J. Willis Fleming, Esq., Chilworth, was an easy first with well-flowered examples. *Deutzias* made a good display; the first prize plants of *gracilis* from Mr. Mitchell were excellent specimens. Mr. Wills had the best *Spiræas*, while Mr. C. Horsey, gardener to J. C. E. D'Esterre, Esq., Elm Field, Millbrook, staged the finest *Cinerarias*. Mr. Wills won premier award for twelve *Hyacinths*, with well grown dwarf specimens of popular varieties. Specimen stove and greenhouse plants were staged by three exhibitors in fairly good condition, Mr. Peel winning for eight.

Prizes were offered for the best decorated epergne. Three entered, making an interesting display. Mr. Carr, with capital Orchids effectively arranged with suitable greenery, easily won premier award. Mr. Peel second. Miss Wadmore, Basingstoke, in the class for one basket of cut flowers, open to ladies only, made a pleasing exhibit, and was awarded the first prize. Miscellaneous exhibits from Mr. B. Ladhams, florist, Shirley; Mr. E. Wills, Mr. Longster, Messrs. Brightman & Andrews, not for competition, were very interesting.

ROYAL BOTANIC.—MARCH 30TH.

The corridor at Regent's Park was capitably filled on the occasion of this the spring show of the Society, and the exhibits were finely diversified. As has become customary during the past few years, the competitive classes were practically nil, and if it were not for the miscellaneous exhibits the shows would certainly be a failure. It is regrettable that more exhibitors do not come, as it would bring back to mind the Botanic Shows of some years ago. The few exhibits that were staged in the competitive classes were of no special merit, and need not be particularised.

Messrs. B. S. Williams & Son, Upper Holloway, sent a collection of plants, mostly comprising *Azalea mollis*, *Clivias*, and *Amaryllis* in good variety, with some charming Orchids. Miscellaneous plants formed the exhibit arranged by Messrs. J. Laing & Sons, Forest Hill. There were *Clivias*, *Azaleas*, *Callas*, *Acacias*, Ferns, Palms, *Caladiums*, *Cytisus*, with several others. Messrs. J. Peed & Sons, Upper Norwood, arranged a bright group of flowering and foliage plants, as did Mr. G. Kelf, gardener to Mrs. Abbot, South Villas, Regents Park. *Hyacinths* and *Tulips* were conspicuous in the latter stand. Messrs. W. Cutbush & Son, Highgate, sent yellow *Callas*, *Oranges*, *Acacias*, *Ericas*, and others in good condition and great variety.

Messrs. J. Hill & Son, Edmonton, staged Ferns, and Mr. W. Kemp, Barnes, *Mollis Azaleas*. Mr. H. B. May showed a few Ferns, and Mr. W. Rumsey, Waltham Cross, some charming Roses in variety. Mr. W. Grant, Newport, Mon., was represented by a collection of *Narcissi*, amongst which were observed some good flowers of well-known varieties. Messrs. B. S. Williams sent floral devices of Roses, Lilies, Daffodils, and others. Messrs. J. Laing & Sons were represented by floral arrangements, some of which exhibited good taste, while others were rather too stiff. Messrs. Moule & Co., Finchley Road, sent *Azalea mollis* and splendidly grown *Mignonette*; while Messrs. J. Carter & Co., Holborn, staged *Cinerarias*, as did Messrs. A. W. Young & Co., Stevenage.

Messrs. H. Low & Co., Enfield, sent an interesting group of Orchids; and Mr. T. Jannoch, Dersingham, finely flowered Lily of the Valley. A handsome collection of Daffodils was staged by Messrs. Barr & Son, Covent Garden, the varieties being mainly represented by masses of

considerable size. The flowers were of good substance and colour. The St. George's Nursery Co., Hanwell, staged well-grown *Cyclamens*; and Messrs. W. Paul & Son, Waltham Cross, some grand *Hyacinths*. All the best known varieties were represented, as well as some of the newer ones. The same firm also sent a number of Roses in pots. The plants were carrying good flowers. Messrs. Paul & Son staged *Camellias*, both in pots and in a cut state, the flowers all being of the best quality. Mr. T. S. Ware, Tottenham, staged excellent Daffodils and alpine plants in variety.

THE YOUNG GARDENERS' DOMAIN.

POTATOES FOR EARLY WORK.

In most private gardens where early vegetables are required Potatoes are forced either in pots or heated pits. If the former plan be adopted good results may be had by the following method. About the 1st of January place the tubers singly in 8-inch pots (using those about the size of small hen's eggs for seed) in a compost of loam, leaf soil, horse manure, and old potting soil in about equal parts, with one good crock and a handful of horse manure for drainage. About half fill the pots with compost and put in the tubers, just covering them with soil; stand the pots in a vinery that has just been started, where they will soon commence strong growth. When the growth is a little higher than the pots the plants should have a top-dressing of the same compost, filling the pots to within about 2 inches of the rims. Care must be taken not to give too much water at first, but a plentiful supply will be needed as they advance in growth. When they have abundance of haulm liquid manure should be given occasionally, and a good crop may be had by the 1st of March. Among the best sorts for forcing are Sutton's Matchless and Myatt's Ashleaf.—W. W.

IPOMŒA RUBRO-CŒRULEA.

Ipomœa rubro-cœrulea is an annual climber belonging to the large and varied order of *Convolvulaceæ*. It is specially adapted for training on the pillars or trellises in the stove, or in a house of a temperature of not less than 60° at night. In such a structure it will produce an almost endless number of bright electric blue flowers, which are very effective arranged with *Adiantum cuneatum* for table decoration. The flowers only last twenty-four hours; but that is quite compensated by the number one plant produces. I have seen as many as 600 flowers expanded at one time on fourteen plants.

This plant is exceedingly easy of culture, and it is a great pity it is not more universally grown, as it does not need one-half the attention the evergreen species do, while at the same time it is freer flowering. To obtain flowers from the beginning of November till the middle of February the seeds should be sown in the month of June in small 60-pots, giving them two shifts into 24's. The soil best suited for them is a mixture of light loam, peat, and leaf soil in about equal proportions, with a sprinkling of silver sand. Care should be taken with them, as with all plants, in the matter of watering, not to go to excess either way. Too much stimulant should not be given, as it causes the foliage to fall or become discoloured, which is regrettable, as the natural colour of the foliage greatly adds to the beauty of the plants.—S. S., *Lockinge Park*.

THE ALTERNANTHERA.

The several varieties of this charming Brazilian plant are so extensively used for carpet bedding that it has become almost indispensable in the flower garden. Moreover, the requirements to insure its successful cultivation are so simple that a large number may easily be raised from a few stock plants. These should be wintered in a warm and airy position near to the glass, and before growth commences in February the plants must be carefully examined for any signs of spider or thrips, which often prove troublesome. An application of some insecticide will save much work later, and I have found that a mixture of softsoap and flowers of sulphur, made soluble, either for syringing or dipping the plants, is the most useful. Syringing on bright days materially assists growth.

By the first week in March cuttings may be taken, and where frames on hotbeds are at command the best way is to insert direct into them, but they do well if pricked into pans or boxes of sandy soil, placed on a hotbed of leaves. Maintain a warm temperature, and shade from bright sun for a few days to prevent flagging. When they are well rooted, however, allow all the light and sunshine possible to develop colour in the leaves. Gradually harden by allowing air and removing into cold frames, taking care to guard against sudden changes, or a check will result, which leaves its mark for a long time.

Of the varieties used for carpeting, perhaps *A. paronychioides* stands foremost, being a free grower, beautifully marked with orange and green. *A. p. major*, and *major aurea* keep a good colour throughout the season. *A. amabilis* and *A. a. amœna* are also very effective in the panels of beds, and form a fine mass of colour. *A. versicolor* is stronger and of more upright habit, rather difficult to retain in some soils. Curiously enough it is easily propagated in the spring, but almost refuses to root later in the season for stock. This difficulty, however, is surmounted by taking up a few plants from the beds and making cuttings with roots attached, or better still, by keeping some growing in pots all the season, and cutting over occasionally to keep them bushy. A few of the highly coloured varieties may be grown in 3 or 4-inch pots, the leading growths pinched back to encourage a compact habit, and used for house or table decoration where dwarf specimens are required.

There is a small thrips, almost invisible, which will devastate a houseful of young plants in a very short time, coming upon the foliage and causing

it to drop off or curl, thereby mutilating the plants. On its first appearance commence a vigorous attack. Fumigation does not disturb its equanimity much; tobacco water, quassia, and other things seem to agree with its constitution, but softsoap bothers it and has the desired effect. If any young gardener recognise the insect, and would state his experiences in combating it, in the pages of the "Domain," many others besides myself would be interested.—R. A. ANDERSON, *Alnwick*.

YOUNG GARDENERS' PREMIUMS.

It seems to me that the subject of premiums is less discussed than almost any pertaining to gardening. Why is this so? Is it because the older gardeners think there is no need for reform, or are the young gardeners somewhat afraid of expressing their opinions publicly? Their opinion of the premium or the premium system, is, I suspect, far from favourable, and this is not surprising, seeing that there are plenty of excellent men in high positions who have never paid a cent for learning.

Some gardeners there are (and I trust many) who take a youth, and from pure love of the work, give him a training in the craft, in the hope that some day he may attain a creditable position. On the other hand, there are men who enter into an agreement to teach a youth gardening in consideration of a fee for doing so; and the youth (or his parents) naturally thinking this will insure his advancement, the fee is paid. Still, how often does it happen on the expiry of the term that a youth finds himself no forwarder than his companions in other places who have paid nothing.

But does the gardener teach him? As a rule does not the teaching fall on the foreman who gets no recompense for it? I have not as yet met a single foreman who was in favour of premiums, and if they keep to that mind when they become head gardeners there is better times for apprentices in store. Many gardeners argue that the premium is a means of keeping gardeners select. That may have been the case in days gone by, but the argument is now obsolete, for there are so many men who spring from amateurs to professionals that the competition in gardening is as keen as in any other profession or vocation. Be that as it may, the premium system is a means of deterring many ardent, industrious, earnest youths from becoming gardeners.—REFORM.

FRUIT FORCING.

Cucumbers.—The bright sun has caused plants kept close during the severe weather to flag, and therefore light shading is desirable for a couple of hours at midday when the sun is powerful. Plants in bearing will need water with a little nourishing food in it once or twice a week, and the roots earthing occasionally. Old plants that have been in bearing some time should have the exhausted soil removed, not injuring the roots, adding a rich lumpy compost previously warmed. Exhausted growths should be cut out and young bearing shoots encouraged. Damp the floors and other surfaces in the morning and evening, and syringe the plants lightly on fine afternoons. Attend to stopping and regulating the growths not less frequently than once a week. To keep the plants in steady progress and secure straight, tender, crisp, well-flavoured fruit, a temperature of 65° to 70° at night, 70° to 75° by day artificially, 80° to 85° with sun, closing sufficiently early to run up to 90° or 100°, with abundance of atmospheric moisture, will be suitable. Ventilate early but moderately, avoiding sudden changes of temperature; pernicious cutting winds and currents of cold air cripple the foliage and deform the fruit.

In pits and frames the necessary heat should be maintained by renewing the linings, taking care to keep rank steam out of the frames. Train the growths rather thinly, and stop them one or two joints beyond the show for fruit. Supply fresh soil to the hillocks or ridges as the roots extend, and be careful in the application of water. Admit a little air early, so as to dry the foliage before the sun acts powerfully upon it. Keep the temperature through the day at 80° to 90° from sun, and close early in the afternoon, no harm accruing if the temperature rise to 90° to 95°, provided there is no rank steam.

Melons.—When the earliest plants are in flower and during the setting period water should only be given to prevent flagging, and the atmosphere must be kept drier, with an increase of temperature of about 5°. Fertilise the blossoms every day, pinching each growth at the same time one joint beyond the fruit. When the fruits are set and about the size of a bantam's egg give a thorough watering with tepid water or liquid manure, having the soil for earthing the roots warmed. Stop the subsequent growths to one or two leaves, and avoid overcrowding by removing superfluous growths. Maintain the bottom heat between 80° and 85°. The night temperature should be kept at 65° to 70°, 70° to 75° by day from fire heat, ventilating from that point, but allowing an advance to 85° or 90°, closing between these figures sufficiently early to run up to 90° or 100°. Syringe moderately about 3 P.M. on bright and warm afternoons, or soon after midday when the air is sharp. Damp the floor in the morning, and keep the evaporation troughs charged with liquid manure. Liquid manure will be needed by plants in restricted borders,

and a mulching of rather lumpy manure encourages roots and affords support.

Later plants will need the growths trained regularly, removing the laterals on the stem to the trellis, then rubbing off every alternate lateral directly they are perceived, leaving the rest right and left of the main stem, pinching the point out of the primary stem after it has extended two-thirds across the trellis. Increase the supply of water as the days lengthen, but avoid making the soil too wet, and secure a genial condition of the atmosphere by damping in the morning and lightly syringing on fine afternoons. Sow seeds to raise plants for occupying small houses or pits as they become cleared of bedding plants, keeping the seedlings sturdy and not allowing them to become root-bound.

Peaches and Nectarines.—*Earliest Forced Trees.*—The trees must not be hurried during the stoning process, but continue the temperature at 70° to 75° by day with sun heat, and about 65° in dull weather. Tie the shoots to the trellis as they advance, and regulate the growths for future bearing, so as not to have them too crowded. Shoots more than 14 inches long that are not required for extensions may have the points pinched out. When the stoning process is over the fruits will require regulating for the swelling period. Supply weakly trees with liquid manure, and inside borders must be kept properly watered, mulching the surface with partially decayed manure. The temperature may be increased to 65° or 70° at night, and in the day to 70° or 75°, maintaining 85° or 90° throughout the day by sun heat; ventilate from 75°, and close early with plenty of atmospheric moisture. The very early varieties will soon give indications of ripening, when syringing must cease, and the leaves that shade the fruit must be drawn aside.

Trees Started at the New Year.—The weather on the whole has been favourable to the swelling of the fruits, especially where a genial atmosphere has been maintained, and stoning is commencing. Avoid sudden checks by injudicious ventilation; cold air in the day, causing excessive evaporation, and too high a temperature at night are fatal.

Trees Started Early in February.—These have firm-textured and deeply coloured foliage when properly attended to, the set of fruit being satisfactory, and the swelling progressive. Syringing as soon as the fruit is fairly set on all the trees assists them to shed the remains of the flowers. Heavy syringing must be avoided; an occasional effective and judicious syringing is all that is needed until the foliage attains to nearly its full size in the first leaves. Maintain a night temperature of 55° to 60° in mild weather, ventilating from 65°, permitting an advance from sun heat to 70° or 75°, but with free ventilation.

Trees Started Early in March.—These are now flowering well. Provide a little ventilation constantly at the top of the house, and lose no opportunity of ventilating freely. The night temperature should be 50° in mild weather, falling 5° to 10° through the night, and in severe weather 50° to 55° by day and 65° from sun with a free circulation of air. Let there be no mistake as to the moisture of the inside border, giving a thorough supply of water when required.

THE KITCHEN GARDEN.

Asparagus.—If the beds were heavily dressed with manure, and the soil from the sides and alleys distributed over this—an old but faulty practice—the surface ought now to be lightly forked over, all stones and sticks removed, and enough of the top-dressing be raked off to cover the roots exposed when the sides were chopped down. It is a mistake to rake off all the soil and manure to the extent of nearly baring the crowns. Now is a good time to top-dress shallow beds with a mixture of fine loam, leaf soil, sand, and fine mortar rubbish. Do not disturb the soil in the alleys, as this ought to be occupied with Asparagus roots. If shallow beds are not top-dressed, the least that can be done is to hover strawy manure over them with a view to protecting the young shoots.

Manuring Asparagus.—Salt is often applied to Asparagus beds, and answers the double purpose of stimulating the growth of plants and destroying weeds. It should be used somewhat freely, or enough evenly distributed to well whiten the surface of the beds. Applied to newly formed beds, salt is liable to seriously injure the roots, and has been the cause of numerous partial or complete failures. Clayey soils are made still colder and closer when dressed with salt, and in all cases where the beds are formed with soils of a clayey nature, salt should not be applied unless, unfortunately, weeds cannot be kept down, otherwise than by its use. Guano and special manures applied as recommended by the vendors, greatly benefit Asparagus, but do not check the growth of weeds. Liquid manure, applied now, and again when cutting has ceased, acts beneficially, especially in the case of the lighter non-retentive soils.

Seakale.—Seakale that is planted permanently, and either forced or only covered with blanching material, ought not to be allowed to form stems much above the ground. After the blanched tops have been removed, cut all stems exposed down to the ground. They will break strongly, and if the shoots are freely thinned out three or four strong crowns will be the ultimate result. Where Seakale can be forced in Mushroom houses, or other heated structures, this simplifies matters, as it is less trouble than forcing permanently planted roots with manure and leaves. Single roots 2 to 3 inches in circumference for forcing can be grown in a single year from root cuttings, each when lifted and forced giving one strong growth and two or three smaller in size. All the thongs or thickened roots should be saved at lifting time, and these cut up into lengths of 5 inches, should be planted in March or early in April. If these cuttings are prepared in January or February and packed in soil or moist sand in a cool place, they form roots and buds by planting time. Seakale should be planted in a moderately rich, finely divided soil, dis-

posing the cuttings 1 foot apart in rows 18 inches asunder. The top of the cuttings ought to be sunk slightly below the surface of the ground. If permanent beds are formed with young plants from a seed bed or nursery, cut off the crowns to prevent their flowering, and plant either singly or in groups of three, disposing the stations 2 feet apart each way. A width of 4 feet of ground is not too much when a single row of Seakale for forcing where grown is formed.

Kidney Beans.—It is too early to sow seed in the open with a good prospect of a crop resulting, but as it is scarcely possible to grow too many Beans for use early in the season, a goodly number of plants should be raised for planting under hand-lights in pits, glazed or unglazed, and frames. They move best out of small pots, and form a good succession to early Potatoes, levelling over the soil and planting the Beans as each light is cleared. At this period of the year Kidney Beans succeed better in boxes than pots, suffering less from drought and red spider.

Tomatoes.—Plants intended for putting out against sunny walls or quite in the open late in May or early in June, should not have been raised yet, especially if large numbers are required. A few might be given a shift into 6-inch pots, and kept growing, not losing their first bunch of flowers, but this is out of the question on a large scale. Plants large enough for turning out into the open ground at the proper time can be had in about a month from the date of sowing the seed, and with only a warm frame or greenhouse at command six weeks is long enough to allow. Sow seeds of early ripening varieties very thinly in pans of light soil in gentle heat. Before the seedlings become drawn raise them up near to the glass, and when in rough leaf place them singly in 2½-inch pots. Grow the young plants in a sunny position.

THE BEE-KEEPER.

CONDITION OF STOCKS.

WHAT is the condition of the bees in the various districts throughout the country, and how have they wintered? are questions often asked at this season. It is gratifying to record the general good condition of stocks. They are, as a rule, more forward, and have more bees individually than is usually the case six weeks after this date. This is our experience in a fairly large home apiary, and is also the opinion of several correspondents in different parts of the country. We have not received such good reports so early in the season before. The only complaint in a few instances has been shortness of stores. This, however, can be remedied when steps are taken in time.

Where numerous colonies of bees are kept one may now easily make a comparison as to the amount of stores consumed during a mild open winter, one unusually severe, and an excessively wet season. The past winter has been exceptionally dry and mild, and our experience is that more stores have been consumed than in previous winters when the weather has been severe. Although this has been the case not a single stock has required feeding up to the present time, and to all appearances they are safe until their natural supplies come in. A wet season is to be dreaded by bee-keepers more than a severe one. Let the hive become saturated, or the floor board damp for any length of time, and the bees will suffer, if they do not actually succumb, so instead of strong colonies in early spring they will, with only a few exceptions, be weak.

DEARTH OF DEAD BEES.

A remarkable feature of the past winter is the scarcity of dead bees in the hives. Our usual practice during early spring is to place a clean dry floor board under each of the hives, as there is always a certain amount of debris to be cleared away, caused by the uncapping of their stores during the winter months. There are usually a few dead bees, sometimes more than others. We have always found them to be more numerous when there has been dampness in the hive than from any other cause. But lately, when removing the floor boards from our hives no dead bees were seen. This can only be accounted for by the mild dry winter, the old bees, which under ordinary circumstances would have died, having had their lives prolonged. They will be an advantage in helping to keep up the temperature of the brood nest. In no instance this spring have we observed any dead bees turned out of the hives, neither has there been any seen in the vicinity of the apiary.

So, taking all things into consideration, the outlook is encouraging to bee-keepers, and should the much needed rainfall come in due course, and warm weather and bright sunshine when the honey flow comes, it will give a stimulus to bee-keeping.

QUEENLESSNESS.

Why are there more stocks queenless at this date, or during early spring, than at any other time of the year? That such is the case few bee-keepers will deny. How often one hears the complaint from the straw skepist, it may be in February or as late as May, that "sundry skeps of bees are dead; there were plenty of stores still in the hive, but the few bees that remained in the skep were found dead

on the floor board." We have received a query similar to the above, and have no hesitation in saying that in nine cases out of ten it is caused by queenlessness. This is oftener observed when care is not taken in making a note of swarms casts or old stocks, as the case may be, when driving the bees in the autumn. The mistake many cottagers make is to keep their heaviest hive for stock. This is invariably the first swarm which is headed by the old queen from the parent stock. When this is done it must end in disaster sooner or later.

But queenlessness at this season is not confined to the straw skep; it will often happen in the modern frame hive. Old age and raising queens late in the autumn are the most frequent cause. Unless there is some particular reason, a queen should never be kept longer than two years. When a queen has become decrepit and worn out from old age they will often live throughout the winter, and then, owing to their ovipositing powers being on the wane, the workers will ball them and turn them out of the hives. If in early spring they will form queen cells; but if a queen should be hatched she will not become fecundated, and the bees will gradually dwindle away. But if the weather is warm they will often leave the hive in a body, and join the bees in another.

An old queen will often die at midwinter; the bees left in the hive then appear to die at a rapid rate, and the fact may not be discovered for several weeks. But when it takes place during the spring the bees should be united to the nearest colony, as advised in previous notes. It is quite easy for a practical bee-keeper to form a reliable opinion as to whether a stock is headed by a good fertile queen or not. If it is, observe them when the sun is shining brightly, and all will be activity; the bees will be carrying in pollen at a rapid rate. If queenless, the bees will remain about the entrance in a languid kind of manner. When this is observed the stock should be examined.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

* All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8, Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Wednesday Morning's Letters.—Letters and parcels which arrive on Wednesday morning can rarely be attended to, and replies published in the current issue. Some parcels and letters are delayed in delivery through being misdirected. The correct address for everything intended for the Editor is given above.

Camellias (Amateur).—If you will comply with our simple conditions above, as other inquirers do, we will answer all the questions you like to ask, and more than this expression of willingness cannot be expected under the circumstances.

Dracaena Leaf Spotted (C. L. H.).—The small spots on the leaf, dark in the centre, with a yellowish ring around, are due to a minute parasitic fungus (*Septoria insularis*), which causes the premature decay of the affected parts. It chiefly attacks the lower leaves, especially of plants grown in a somewhat low temperature, and during the winter or early spring months. The best preventive is sponging the leaves occasionally with any of the advertised insecticides containing soap, as most of them do, being more or less emulsions. Such adhere to the cuticle and even sink into the pustules, therefore apply with a sponge to effect that object.

Diseased Neapolitan Violet (H. L. C.).—The plant is attacked both at the root stems and in the leaves by the Violet disease fungus (*Peronospora violæ*). It is mainly induced by a stagnant atmosphere, not necessarily by keeping the lights of the frame closed, but through the plants being very close together and dense in the crowns, so that air does not circulate freely through them. The plant had at least a dozen apologies for crowns, and, in consequence, very weakly and crowded. We mention this, as to have healthy plants they must be from individual suckers or offsets planted singly each spring, at least 9 inches apart, in good rich rather firm soil in an open situation, kept free from runners and weeds during the summer, and properly supplied with water and nourishment. For repressing the fungus use a mixture of charcoal dust and air-slaked lime, dry and floury, dusting the plants lightly, and keeping them free from all dead or decaying leaves. This treatment answers well with us. Such plants as the one sent cannot possibly be satisfactory.

Boiler Leakage—Cucumbers, Tomatoes, and Mushrooms (A. D. H.).—Drive in the "tow" as you propose with a mixture of red and white lead, and bind a thick plaster of this mixture, if you can, tightly round the faulty part, which may be in one of the tubes. You will find practical information on "Cucumber and Tomato troubles," and how they were surmounted, by Mr. Iggulden, in the issues of the *Journal of Horticulture* of February 18th, March 4th, and April 1st, 1897. Mr. Mortimer's method of growing Cucumbers in a small quantity of soil is described by Mr. Dean in our issue of May 20th of the same year; and an excellent article on growing Mushrooms for market, by one of the most successful cultivators, was published on February 10th, 1898. The five numbers, if in stock, will be posted to you in return for 1s. 5½d. sent direct to the publisher, 12, Mitre Court Chambers, Fleet Street, London, but you must be careful to quote the dates we have given. You can also obtain Wright's "Mushrooms for the Million" (which has been helpful to many, including the writer of the article alluded to) from the same address for 1s. 3d., or by ordering through a local bookseller for 1s.

Tuberoses (E. T. S.).—These plants are usually grown and flowered in pots, but we have seen them flower freely in the open air. You had better pot the tubers on arrival in the same way, and in similar soil as you would Hyacinths, burying the pots in cocoa-nut fibre refuse or other suitable material, say under the close stage of a greenhouse, where no drip will reach them. If the soil is pleasantly moist when used no water will be needed if they are covered with damp material as soon as potted. When growth has fairly started withdraw the pots, and gradually inure the plants to the light, taking care that the soil does not get too dry. As growth advances syringe the plants daily in bright afternoons, and as the weather becomes warmer place them in a frame, keeping it rather close for a time, then gradually increasing the air for preparing the plants, as if they were Dahlias for planting out early in June. If you make no mistake in carrying out the advice given you may succeed in your object. The plants should be kept steadily growing without check. We have known tubers planted directly in the open at the end of May grow and flower towards the end of the summer, though some failed.

Eurycles Cunninghami (J. C. S.).—This is an Australian Amaryllidaceous plant near *Paneratium*. To be grown well it should be given a place in the stove, and be treated in a similar manner to *Eucharis* during the season of growth. Unlike *Eucharis*, however, it is deciduous, and requires a thorough rest during winter. Plenty of water should be given while growth is active, the supply being gradually withheld as the leaves show signs of decay in the autumn, no water at all being given during winter. At the beginning of March growth will commence, flowers being produced with or soon after the development of the young leaves. The best time to repot is in March, a compost such as is used for *Eucharis* being suitable. The plant does not resemble the white variety of *Agapanthus umbellatus* in any way. The foliage is very like that of *Eucharis amazonica*, but not so strong. The flowers also resemble somewhat miniature flowers of that plant. They are white, about 1½ inch across, and produced ten or more together on scapes 1 foot high. The species was introduced from Queensland and named after its discoverer in 1824, and was figured in the "Botanical Magazine" in 1835, t. 3399.

Various Plants (R. C. N.).—*Solanum jasminoides* is a greenhouse, wall, or pillar plant, as free in growth as a Jasmine when planted out, and it is better so, with its roots limited to a narrow border, than grown in a pot. We have seen it 15 feet high, covered with white flowers, in a house from which frost was excluded. It may be increased by cuttings in sandy soil under a bell-glass in genial heat in the spring. *Streptosolen Jamesoni* may be grown in the same way, but requires a warm greenhouse; it can be grown and flowered in pots, either in a small state, or shifted into larger and trained as free pyramids. It is beautiful in any form by its orange-scarlet flowers. Mr. Bennett Pöe usually exhibits handsome specimens at the May shows of the Royal Horticultural Society. Propagation is effected by cuttings, in the same way as the *Solanum*, but preferably with a little more heat. It is worthy of extensive cultivation. New Zealand Flax, popularly Flax Lily, botanically *Phormium tenax*, is occasionally seen in conservatories. It produces persistent leaves, 4 to 6 feet in length, and 3 or 4 inches in width. The dwarf form, *P. t. Veitchianum*, with its striped leaves, is the more ornamental and generally cultivated. *Phormiums* are increased by seeds and division. The Cactaceous plants to which you refer are *Phyllocactus Thalia*, which produces beautiful large crimson flowers, suffused with violet; and *P. Vesta*, which has pure white flowers. They are varietal forms, raised in the Chelsea establishment of Messrs. James Veitch & Sons, Ltd. The flowers are only of short duration. You do not say what kind of information you require, and trust that what we have said will to some extent meet your wishes.

Violets Damping Off (A Reader of Our Journal).—The Violets are simply damped through the foliage being forced and then subjected suddenly to cold. This is a common failing of the Neapolitan and the form of it known as Marie Louise—the lavender flowered variety with a white eye, not the deeper coloured form, which, with the variety you name, is much hardier in both flower and foliage. There does not appear to be any trace of Violet disease (*Peronospora violæ*) fungus, but there may be some on the root stems (see reply to "H. L. C."). We can only advise more careful ventilation, but with security from frost.

Marechal Niel Rose Blooms Damping (Gardener).—There was nothing of an organic nature to injure the buds. They had evidently suffered from some constitutional defect, probably lack of nourishment. Under similar conditions we have known a little extra feeding with a quickly acting fertiliser produce satisfactory results, a small pinch of the following mixture per pot acting like a charm:—Phosphate of potash three parts, dust charcoal one and half part, and sulphate of ammonia one and half part, mixed, a thimbleful sufficing for an 8-inch pot. It is difficult to account for some blooms being affected and others not; but the position of the plants and differences in vigour of the growths may account for the divergences.

Foster's Seedling Vine Leaves Curled (W. C.).—The cutting away of the Black Hamburgh on which the Foster's Seedling was grafted five or six years ago is sufficient to account for the crumpled condition of the leaves and somewhat stunted growth, as there would be a considerable deprivation of support. There is no disease, or anything than that stated to indicate the cause of the present condition of the growths. You say "the cut-back stem has not bled a drop," and that the top shoot of the Vine is all right. Just so, the flow of sap being always strongest at the extremity, and there was not sufficient for all the growths. No doubt the Vine will come stronger later on—that is, when it has made roots corresponding to the top, or sufficient to supply the requisite sap. As for the one shoot on the Black Hamburgh adjoining going in the same way, we can form no opinion as to the cause in this particular instance. Such isolated occurrences are not uncommon in vineries, and may arise from variations in bud development and maturation.

Planting Vines (G. Simpson).—The Vines should be planted out without delay, especially as they have not been cut down, which must not now be done, as they would no doubt bleed, and this weakens and retards the growth. Instead of shortening, rub off the buds at the upper part of the cane and down to a couple of buds from the base provided these are in a light position, and when the shoots from these are a foot long the cane may be cut away. Reserve the most promising shoot, cutting off the other when the one selected has got a good start. This will give you a stout cane, and a free rod has considerable value in after years. With good management the Vines will grow 20 feet or more, and can be cut down next season to three buds above the lowest wire of the trellis. By leaving the Vines full length now the growth will be relatively weak, though you may, if the wood of the canes is well ripened, allow a few more buds to start, pinching all but the leader. The other plan, however, is the more satisfactory in the end.

Seedling Cyclamens (J. Thomson).—The seedlings ought now to be placed singly in 3-inch pots, and after April grown in frames during the summer, with plenty of air after becoming established, shading from bright sunshine, a single thickness of tiffany when the sun is powerful being sufficient. By July most of the plants will have filled the pots with roots, and they should then be shifted into 5-inch, or if the plants are very strong into 6-inch pots, in which they will flower. Good drainage must be provided, and a compost used of turfy loam and leaf soil in equal parts, with a free admixture of sharp sand. The roots proceed from the base of the fleshy rootstocks, and these should only be about half covered with soil, leaving the tops clear from whence the leaves and flowers proceed. The plants must be kept near the glass to prevent drawing, shading in bright weather only, watering liberally, but not excessively, and sprinkling them on fine afternoons to encourage growth and keep the plants free from red spider and thrips. The plants should be housed in September, assigning them a light position in a greenhouse; but they flower best in a temperature of 50° to 55°, though when in bloom they last much longer in a temperature of 45°. They require a humid atmosphere during the summer, and the pots should stand on a damp base, not on dry boards or an open stage.

Figs Going Off (Wilts).—The cause is the failure to flower, and that is induced by excessive vigour, or the drawing away of nourishment by the growth. Thus Fig trees grown for the first crop are often stopped very closely at the commencement of growth to concentrate the energies on the Figs, and very little syringing is practised, as this tends to promote wood growth, and also interferes with the opening of the fruit for aëration of the flowers. Of course root action has a great deal to do with the vigour, the trees often being too rampant in growth, which can only be overcome by lifting and confining the roots to narrow borders of calcareous and firm material, then the trees grow slowly, sturdily, and fruitfully. After the fruit has taken its first swelling, and remains stationary for a time, water should be kept from the apices, then they will flower, and after that swell freely up to changing; when ripening, water must again be kept from the fruits. Fig trees are almost always trained with the points of the shoots away from the sun, and their last made growths, where the first-crop fruits are produced, do not get well ripened, then, when the rush of sap comes in the early stages, away the trees go to wood. In a house where Figs always cast the fruit, the trees on being moved to the back of the house, confining the roots to a narrow border, and training the shoots down the trellis, gave grand results in both the first and second crops, because the growth was then sturdy and the points thoroughly matured.

Tomatoes on Ashes (S. J.)—Your plan will do very well, or the ashes might extend beyond the boxes. Liquid manure would be wasted on them now. Plant nutriment will be washed into them from the boxes by the time the roots protrude. There are two kinds of superphosphate—bone and mineral, the former containing a little nitrogen, and that is why it was recommended. When the boxes are filled with roots you should add periodical top-dressings of rough rich turfy loam, which will become interlaced with roots for imbibing liquid nutriment. When the plants are bearing, much water will be needed.

Palms Raised Out of the Pots by Roots (G. S.)—You may cut off the lower part of the roots with a sharp knife, thus making the roots fit the pots and allow for a little fresh soil. Such practice, however, checks the growth. A wire edging placed around the rim of the pot to the height well above the roots of the plants, and this receptacle filled with fibry soil, using moss outside, answers for a time. We have had plants very useful in that way by having *Selaginella denticulata* growing on the basket-like girdle. The plants ought to be given larger sized pots, for to starve Palms, is to ruin them. Why not exchange them for smaller?

Artificial Manure for Nut Trees (F. M. M.)—The best we have seen used was equal parts of soot and air-slaked chalk lime by measure, half a pound of the mixture being applied per square yard and pointed in lightly. The following also answers well. Bone superphosphate, dry and crumbly, six parts; double sulphate of potash and magnesia, three parts; and sulphate of lime, one part, mixed, using 4 ozs. per square yard. This should be pointed in lightly, the dressing extending from the stems to the outside of the spread of the heads. For Hollies and Conifers—rape meal, five parts; steamed bone meal, three parts; sulphate of potash, two parts; and air-slaked chalk lime, two parts, mixed. Of this use 4 ozs. per square yard, and point in, or, if there are roots near surface, cover with a little soil.

Propagating Tuberous Begonias (W. C. S.)—The dry tubers ought to be started in boxes of leaf soil rather than in pots in gentle heat and a moist atmosphere. When both top and root growth have commenced cut up the tubers into as many pieces as can be had each with a shoot attached, and place them 3 inches apart in equal portions of fine loam, leaf soil, and sand. Keep these divisions steadily growing as before, and when the tops nearly touch each other move the plants singly into 5-inch pots, or larger sizes if strongly rooted. Tuberous Begonias never start so healthily in small pots as they do in boxes, and the latter are to be preferred for dry tubers, whether they are to be split up or not. One good shoot will usually develop into a strong plant, and if more form on the divisions remove them when 3 to 4 inches long, and insert singly in small pots of sandy soil. In a close frame and moist heat these soft cuttings are liable to damp, and they ought to be placed in a dry heat of 65° to 70°, with a bottom heat of 75°, shaded from sun and carefully watered till rooted. More cuttings may be put in as fast as they can be taken without spoiling the plants. In August cuttings will root if inserted in sandy soil at the foot of a south wall. Late rooted plants will form a small tuber, from which a strong growth may be had the following season.

Boronia megastigma (W. T. W.)—If you have not had experience in growing Heaths, say such as *Erica hyemalis*, from year to year, and raising plants from cuttings, you will not be very likely to succeed with this fragrant *Boronia*. They require substantially the same treatment in not being cut back below healthy leaves, starting fresh growth in a light warm greenhouse, with the pots on a close, not open latticework, stage, bringing on clear days, never letting the soil get once too dry or too wet, but keeping the roots active in firm sandy peat soil. They are best in frames during the summer. Cuttings are rooted in firm, very sandy peat, surfaced with pure sand, watered, the cuttings, 2 inches long, of rather firm tops, half divested of leaves, then inserted, sprinkled lightly to close the sand round them, covered with a bell-glass, and the pots plunged in a moderately warm pit or frame, shaded as needed for a time, the glass wiped dry daily, and water given with consummate judgment. Many persons have not exactly the right conveniences for propagating and growing the plants in question, and some have failed. If you succeed it will be a feather in your cap. We see no reason why you should not succeed with the *Cannas*. These plants and others you name are ten times easier to manage than Heaths, and the Heath-like *Boronia* and *Leschenaultias*.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*M. L. G.*)—1, *Iris chinensis* (fimbriata) (*Capel*).—A good form of *Camellia japonica*. (*A. A. T.*)—Though we do not undertake to name wild flowers, we give the names of those you have sent. 1, *Lamium purpureum* (Purple-flowered Dead Nettle); 2, *Mercurialis perennis* (Perennial Dog Mercury) male plant; 3, *Capsella bursa-pastoris* (Shepherd's purse). (*E. H.*)—1, 2, and 3 are all forms of *Dendrobium nobile*; 4, a variety of *Dendrobium Leechianum*.

POTATO EXPERIMENTS.

THE results of two sets of experiments in the growing of Potatoes have been recently published, and they are interesting as showing how much may or may not be learnt from them according as the conditions are favourable or otherwise.

It is too often the case that experiments are conducted in a way and under circumstances that are very far removed from those ordinarily met with on a farm; and for the average farmer, unless he can make allowances, knows his lesson beforehand, and therefore is able to read between the lines of the report, they are of little educational benefit.

The Cheshire County Council has inaugurated a series of experiments in Potato growing, and last season the first crop of the series was grown at their Agricultural School at Holmes Chapel. Unfortunately the field on which the Potatoes were grown has been recently ploughed up from old pasture, having grown a crop of Oats in 1896, and been grass for at least eighty years previously.

As the soil is heavy, there is a very large store of unexhausted fertility which must take the crops several years to reduce to ordinary farming condition. It is evident, therefore, that whilst the general results are good and conditions favourable for an equal test of the capabilities of the several varieties on a virgin soil; on ordinary farm land much greater variations might be found to exist between the different sorts as regards cropping qualities.

For instance, early kinds which never grow too much top would be favoured by a rich soil, whereas a vigorous late variety, such as would be suitable for medium soil, would grow too much haulm and a rough sample of tuber on newly taken up land.

The Oats in 1896 were not manured, but last year 20 loads of farmyard manure, 4 cwt. superphosphate, 1 cwt. kainit, and $\frac{3}{4}$ cwt. sulphate of ammonia per acre were applied for the Potatoes, and such a tilling as this should produce an excellent crop even on poverty-stricken land.

The varieties chosen to experiment upon were not very representative ones, most of them being comparatively new; this latter, however, might be a good feature. The Bruce was the one most generally known to the farming world.

The results were wonderfully even, the early kinds producing about 10 tons, and the second earlier about 14 tons per acre. Of the later kinds, Up to Date produced over 17 tons, and Bruce over 13, and these were respectively first and last in this section. Now, we have found that Up to Date can beat Bruce by much more than 25 per cent.; in fact, we have grown it two years, and each year it has just given twice as heavy a crop as the Bruce. Our experience of the two varieties convinces us that on ordinary arable land the Bruce is not in the running at all with Up to Date, but with very high cultivation it might more nearly approach to it. This view seems to be borne out by the result of the Cheshire experiments. There is one lesson also to be learnt from them, and that is that the Bruce is still one of the most valuable Potatoes for resisting disease, as it is easily at the top of the tree as regards soundness.

The other set of experiments to which we have referred is that worked by the Irish Congested Districts Board during 1897, and from this series we think much valuable information may be gleaned. Several well known varieties were tested side by side on ninety-seven plots to ascertain which was the best to take the place of the Scotch Champion. The varieties included the following well-known sorts—Beauty of Hebron, Up to Date, Antrim, Beauty of Bute, Garton, Maincrop, Irish White, and Champion. As the trials were spread over a large variety of soils in very widely differing stages of fertility, the net average results are far more instructive and valuable than those of the Cheshire County Council alluded to above.

For one thing, instead of an equality of results which the Cheshire experiments practically amounted to, we find in these Irish experiments very divergent returns, and as a whole the lesson learnt is that the Scotch Champion still fairly holds its own, easily distancing all competitors but one. This one, however, is proved to be distinctly its superior, and far away in advance of all the other kinds tried. The Irish White did fairly, but not as well as the Champion, and of the others the Antrim and Maincrop came in about an equal fourth. The results, as regards keeping qualities, are not yet published, but we should fancy that the Maincrop would stand well in this respect.

There is, however, one very striking result which is common to these two widely different sets of trials, and that is the distinct superiority of the Up to Date; and when we remember the wonderful result of the Lancashire County Council tests of 1895, when manures were really the subject of trial, but where the Up to Date easily out-distanced in every case the other excellent varieties used, there is only one conclusion to be drawn, that in the Up to Date we

have the Potato of the century. The Magnum Bonum was a great find; but Up to Date, as a cropper, is so immeasurably superior to everything that has been seen that it is almost a miracle. It has large size, good shape, and most vigorous constitution, the haulm being far in advance of any other variety for size and stability. As to quality, opinions differ at present; but if we were to hazard an opinion we should be inclined to say that the quality is too good to last. The demand for seed has been so great in our neighbourhood that £7 and £8 per ton has been a usual price, and offers can only now be obtained of very small quantities at fancy prices and quite as a favour.

What is most wanted now is a good second early. Up to Date has only one fault—viz., lateness. Can anyone find us a Potato as good, but to ripen in August? We should be only too glad to give it a trial.

WORK ON THE HOME FARM.

This is the time for sowing grass and Clover seeds, and though a few may have been sown, the bulk has yet to be put in. Many farmers like to sow their Clover with the seed grain, and even drill it mixed with grain, but this latter method results in burying the small seeds too deeply. They should be well covered, but near the surface, and they like a firm seed bed.

Small seeds are not easy to sow by hand, and now that good sowers are becoming so scarce, small seed drills are generally used; we, however, do not like them, unless they are used for simple broadcasting. The most successful method we know is to Cambridge roll the land, and broadcast the seeds either by hand or drill; the seeds fall into the numerous little furrows made by the ring roller, and a light set of harrows will cover all up, and still they will be quite near the surface. Heavy soil might have a flat roll over it after the harrows, but very light land would be better as the harrows leave it, for high winds sometimes make bad work of light soil if left too fine and smooth.

We have had a little rain, and the land harrows rather better; but Turnip land recently eaten off is turning up very rough, and requires a heavy rain to make anything like a fine mould.

Wheats are looking wonderfully well; they have been once more rolled, and will now have a good harrowing. A dressing of nitrate of soda will be given where needed in about a fortnight. Last year we used sulphate of ammonia as being relatively cheaper, but prefer nitrate when, as at present, it is the cheaper form of nitrogen available.

Pastures have been much refreshed by the rain, partial though it has been, and there is plenty of food for the young lambs. If frosts would keep off there would soon be a good bite for the cattle, and they might be got out from the yards. It is to be hoped we shall have more and copious rain next month, for the small crop of last year's hay is almost gone, and there will be another light crop if the season remain dry. Springs hold out well so far, but we fear they are not likely to stand the test of a long drought.

REMARKS.

- 20th.—Bright almost throughout, but cloudy about 2 P.M.; clear, cold night.
 21st.—Brilliant all day, and clear night.
 22nd.—Fog till 9.30 A.M., then fine, with faint sunshine; thick fog again from noon till 1 P.M.; clearing by 3 P.M., and fine after.
 23rd.—Overcast morning, with drizzle and showers; sunshine at midday and at 5 P.M.; N. gale in afternoon and evening, with alternate drizzle and clear sky.
 24th.—Alternate sunshine and showers of snow in morning, and of sleet and soft hail in afternoon; snow again in evening (snowflakes $\frac{1}{4}$ inch diameter at 8 A.M.); gale in afternoon.
 25th.—Gale, with incessant snow and occasional sleet or soft hail from 6 A.M. to 4 P.M.; overcast after.
 26th.—Overcast morning; rain with occasional wet snow from 2 P.M. to 10 P.M.; gale throughout.
 The latter part of the week very cold, and quite exceptionally uncomfortable.
 —G. J. SYMONS.

CARNATIONS

NEW TREE or PERPETUAL BLOOMING.

LADY GERTRUDE ROLLE.—Rich rose pink, Good sturdy healthy grower, free flowering. Will become popular for market work. 5/.

LADY DOREEN LONG.—Clear yellow, slightly pencilled carmine pink. The largest and most handsome of this class. 5/.

ETTIE MITCHELL.—Clear soft salmon pink. A perfect, large, and smooth flower. Has only to be seen to be admired. 5/.

MRS. RICHARD LEY.—Of the same colour as Mdlle. THERESE FRANCO, but the blooms are larger and of better form, whilst the plant is of superior growth. 7/6.

NELLIE STEVENS.—Pale rose, shaded salmon. Equal to the show selfs in form, strongly perfumed, and will prove a great advance. 7/6.

MRS. HUNTER LITTLE.—Soft salmon pink. A distinct and lovely variety, good in every respect; a charming acquisition. 5/.

For full descriptions of these and other Sterling Novelties in Winter-Blooming Carnations, see Special List, post free.

WILLIAMS' SHADING MATERIALS.

THE MOST SUITABLE FOR
SHADING ORCHIDS, FERNS,
PALMS, and STOVE and
GREENHOUSE PLANTS

It is a strong durable Cotton Netting, woven in squares so close as to exclude the direct rays of the sun, but admitting the greatest amount of light attainable through shading.

Blinds made up and Fixed Complete.

It withstands the weather better than any other class of Shading, and may be beneficially used on account of the thickness of its texture, during cold weather, to keep the frost out. The leading Orchid and Plant Growers in the country have used this material for some years, and speak very highly of it, pronouncing it to be the very best material for plants they have ever used.

Sold in pieces 30 yds. long by 1½ yd. wide, price 40s. each. Samples submitted gratis.

This new Shading is in the form of a white powder, and is prepared for use by applying boiling water to the compound, and allowing it to cool, when it can be applied by means of a brush.

It dries instantaneously, and can be rubbed off easily when moist. This Shading may be used for GREENHOUSES, SKYLIGHTS, WINDOWS, &c.

Sold in 1-lb. packets, with directions for use, price 1s. each.

1 lb. free by parcel post for 1s. 3d.

Each packet will make half a gallon of shading material when mixed. It is a great improvement on anything hitherto offered, and lasts the whole season.

1898-FORBES' CATALOGUE-1898

(Over 150 Pages, nearly 150 Illustrations)

Of FLORISTS' FLOWERS and HARDY BORDER PLANTS, is got up regardless of trouble or expense, with the result that it is by unanimous consent pronounced the most comprehensive, most accurate, most reliable, most complete, and best extant.

It gives full and accurate descriptions of everything in the way of Florists' Flowers, also colour, height, time of flowering, and price of all the best Hardy Border Plants, together with their English or common names, and a mass of other valuable information that cannot be had elsewhere.

It is, in fact, a veritable reference book, invaluable to all growers of these plants, and should be in the hands of all intending purchasers. FREE ON APPLICATION.

THE CHINESE BANANA.

A PROPOS of a query on page 268, respecting the culture of this, one of the most interesting and handsome of our economic plants, I venture to give details of treatment which afforded highly satisfactory results. In direct reply to the question concerning the particular case, judging from the description of the two plants in tubs, there is no need of despair of the fruit ripening, but to assist them in doing so the bunch should, if not already done, be shortened back as far as those "fingers" which have attained to nearly an average length. If it is possible to give the plants some bottom heat, either by standing the tubs upon the hot-water pipes and packing some conducting material about them, or by any other means suggesting themselves under the circumstances, it will probably facilitate matters considerably. As for cutting the "fingers" in a green state—No; only in particular cases, to be subsequently mentioned, is it advisable to do so, for the superiority of the English-grown Banana is dependant solely upon allowing it to ripen naturally.

Musa Cavendishi, probably the only Banana worth cultivating for its fruit (introduced from China in 1829, and apparently disseminated through nearly all tropical parts of the globe), is accredited with producing a larger quantity of food from a given area than any other economic plant. Whether, owing to the cost of production by artificial heat, home-grown fruit could favourably compete with imported produce, is at least doubtful, but the relative position of the two, so far as quality is concerned, is, I think, pretty much that which obtains with the Almerian and Muscat of Alexandria Grapes. Its culture for appearance as a noble tropical plant, which is of the simplest kind, appears to be wholly apart from the methods necessary to insure its success as a fruit producer, hence luxuriant plants are apt to disappoint expectation so far as that is concerned. I must confess that my ten years' experience of Banana culture for fruit commenced experimentally, and for a part of that time was but a partial success. The home-grown fruit, however, was held in such high esteem

by the family, that continual effort was at last rewarded by being able to supply a crop of Bananas annually, from a rather cramped space, with as much certainty as a crop of Grapes.

Under normal conditions of home culture for fruit, young plants—suckers—which are planted in the spring do not show fruit until the summer of the following year, when they have attained a height of from 7 to 10 feet. These fully developed plants often produce individual clusters of 90 lbs. in weight. The head room thus monopolised excludes their culture from many gardens where conditions exist similar to those it is proposed to detail. This amounts practically to biennial *v.* annual fruiting with a corresponding limitation of growth; and, it must be added, weight of fruit, for our average weight of the fruit clusters may be given as about 40 lbs. The house, which had originally been built as a Pine stove, and ran east and west, was divided by a walk under the apex of the roof into two hotbeds, one of which, on the southern side, was still retained for Pines, the other being partly devoted to the Bananas. Bottom heat was afforded by six rows of pipes in each bed, and on these thin flags were laid, forming a hot-air chamber. From this foundation, and as close as possible to the walls next the walk, the vertical measurement to the roof gave about 7 feet of head room. Starting with the empty bed, a thin layer of sods was placed grass downwards upon the flagged bottom, and upon this ten plants of Bananas were spaced out 4 feet apart, parallel with and close to the wall nearest the walk, the planting taking place in March. Equal parts of roughly chopped turt and decayed manure were then dressed over the roots about 18 inches deep to complete the planting; a high temperature was maintained and no shading permitted from start to finish, save such as was given by a shelf suspended from the apex of the roof, which broke to some extent the direct rays of the sun at midday.

Every inducement was now given to active growth by copious waterings with warmed water, and daily syringings when the house was closed, the temperature being allowed to run up on bright days to 100° Fahr., whilst the normal day temperature was seldom lower than 80°, and ranged from 70° to 75° at night. Towards the middle of June the plants had developed stout stems about 4 feet high, the foliage being here and there in contact with the glass. The conditions of excitement were now subdued by keeping the plants fairly dry at the roots, admitting more air—submitting them, in fact, to a kind of hardening process. From that time plants were daily watched with some anxiety for signs of fruit conception, for it is of vital importance that the short resting period conducive to it should on its occurring be at once changed to the stimulating conditions of active growth. If all went well, in about three weeks from the check being given a slight swelling of the stem some 6 inches below the base of the leaves would be noticed, and almost contemporaneous with it the last leaf was made, which there is no mistaking owing to its puny size. As soon as this was noticed in the majority of the plants tropical treatment, as previously detailed, was at once resumed, and expectation was soon gratified by the appearance of the great purple-bracted inflorescence, the end of which was cut off as soon as the successively developing whorls of “fingers” showed by a diminution in length that nothing could be gained by its retention. Under the active conditions of growth, still maintained, the “fingers” had generally by August swelled to their full size. From thence the ripening was a question of the family’s requirements as to retarding or *vice versa*. In an emergency some of the “fingers” have been cut green and laid up on the shelf previously mentioned in the sun; but this was always regarded as a sacrifice, for, as stated, they were similar to imported samples.

Naturally ripened “fingers” are of a rich, clear, golden hue, being at the final stage bletted with minute brown spots, when they part freely from the stem, although it is preferable to cut them carefully. At this time it may be necessary to examine the clusters morning and evening to remove those which are ready and prevent their falling. The delicate perfume of the ripening fruit will attract all ants in the vicinity to the feast, but a band of tarred sacking round the stems of the plants, and the bending down of any leaves in contact with the

roof, will obviate this. Suckers which spring from the plants early in the season must be repeatedly cut back to the soil surface until the ruit has swelled. One from each plant, in some cases two, may then be allowed to grow freely, and on the removal of the fruit the parent plant can then be entirely removed by twisting it out.

A few notes in conclusion may be of service. The most important thing in this method of growing Bananas is the resting period, which must also be regarded as the most critical stage of the whole operation. One year, owing to this check being unduly prolonged, the embryo inflorescence refused to emerge, swelling the stems to an abnormal size, and resulting in total failure. Another point to notice is that although our crop was an annual one, the last year’s suckers at planting time were really half developed plants. Under the conditions as described our gatherings of naturally ripened fruit extended generally over three months, and on an average seven plants out of the ten produced good clusters. The last year I thus grew them gave the best results, experience having taught us many things I have endeavoured to show in this paper. In that particular year the whole of our ten plants produced fine clusters, the aggregate weight of which was certainly not less than 400 lbs., and probably exceeded that figure, and I always look back with pleasure upon our endeavour to grow the Chinese Banana under difficulties, and the success which was eventually obtained.—MUSA.

FLOWERS AT THE END OF MARCH.

AMAZONIAN March has passed to her rest for the year, and the flowers of spring come with ever-increasing beauty. Their lot is not a happy one when bitter winds prevail. As this is written a fiercer gale than usual is afoot, and the Daffodils strain at their stems as if they would fain flee away to calmer lands. Few of us care for the month. Very beautiful are these Daffodils, and pitiful as it is to see them dashing out their beauty in the wrath of the gale, we look upon them with delight. The soft beauty of *Narcissus pallidus præcox* Blond d’Or, the deep gold of Santa Maria, the great blooms of *telamoni* plenius fill us with joy, added to by the charms of the others now in bloom. Common as is the last-named, it is unsurpassed in its way, and for the garden and the house cannot well be spared.

Sturdy and tall, of excellent form, and of lovely colour, is Henry Irving. The “prince among actors,” as the celebrated player is often called, has no unworthy Daffodil to bear his name. It is also one of the best of the varieties of the type known as *spurius*, and worthy of growing in large clumps in many gardens, in which it is yet unknown. Another fine Trumpet Daffodil is Mrs. H. J. Elwes, of different form, deeper colouring, and coming a little later into bloom. N. Santa Maria, which has been a little difficult to establish in my garden, seems at length to have made itself at home, and is very effective with its deep-coloured flowers, having the trumpets and perianth segments of uniform colouring. It is said to be “orange-coloured,” which is perhaps a slight play of fancy, but it is in truth the deepest yellow of all. Quaint looks the little double Rip Van Winkle, which, as is its wont, has awoke from its sleep to show its sharp petalled flowers. Others there are, with more to come, and April will be bright with the gold and silver blooms.

Too short-lived, but delightful while they last, are the Dog’s Tooth Violets, with their Cyclamen-like blooms and spotted or marbled leaves. We have many newly introduced species, yet none is more beautiful than the finer varieties of the old *Erythronium dens-canis*, which for long years has been grown in our British gardens. Such varieties as *blanca* (white), *Von Humboldt* (violet), or *rubens* (red), will be found to give much pleasure when their annual blooming time comes round. Gardens vary in their nature, but in some, such as this, planting in shade is found to be detrimental to free-flowering, and nowhere have these Dog’s Tooth Violets looked prettier than by the edge of a gravel walk or in the grass in full sun. Some experiments, continued for a few years, have shown that this applies to such Dog’s Tooth Violets as *Hendersoni*, *sibiricum*, *grandiflorum*, *Hartwegi*, *citrinum*, and others, and the clumps which have been grown in shade and moisture must be removed at the earliest opportunity. The puzzling *E. americanum* is best grown in an enclosed division of the rock garden, in stiff soil, and so planted that it cannot find its way, by means of its young tubers, deep into the ground.

Pretty, also, are the *Puschkinias*, which, after some trouble, seem as if they had now found a suitable place in which to grow. Their

clusters of pale pearly flowers, lined with blue, look very pleasing in a sunny part of the rock garden, where they grow in light peaty soil.

The dazzling Tulip has hardly begun its reign of splendour. It is unfortunate for the garden of hardy flowers that so many are unsatisfactory when planted permanently and not lifted and dried off annually. For many reasons it would be a great gain to have more of these Tulips, which might safely be left alone for several years. In some gardens *T. Greigi* is very accommodating in this respect, and is alike valued for its earliness and beauty. It also is all the better of being lifted occasionally.

A very fine Tulip which has flowered in my garden for three years in succession without removal is *Tulipa Kaufmanniana*, which was found in the mountains of Turkestan by Albert Regel. It has previously been mentioned in the *Journal*, but its beauty entitles it to another notice. Of exceeding beauty indeed is the form here, which is a pretty white with a bright yellow centre, the outside being of a fine red or carmine with a white bordering. The flower opens out quite flat in the sun. The variety of *T. Kaufmanniana* which received a first-class certificate from the Floral Committee of the Royal Horticultural Society appears to have been of a different colour, as it was said to vary from pale pink to pale rosy purple. Mr. H. J. Elwes considers the certificated plant inferior to a form he grew, and which resembled mine with the addition of a carmine band above the yellow centre. It is grown in the border, but a group on rockwork would form a delightful picture when the sun induced it to open its flowers to their fullest extent. Kaufmann's Tulip is one of the noblest of a noble race of garden flowers.

The gale blowing as I write is perhaps the severest of the year, and as with it come showers of snow and sleet, one of which now whirls through the garden, we think of broken flowers and injured beauty. A fine tree Lupin is ruined, Daffodils have been nipped off by the ground, and leaves of many kinds have been driven off the plants; yet through all are the white of the *Arabis*, the blue of the Forget-me-not, the purple of the *Aubrietia*, the yellow of the Daffodils, and colours and shades almost innumerable. The Glory of the Snow is with us yet; the Snowdrop has still a few late flowers. There are Scillas, Anemones, Polyanthus, Primulas, Primroses, Grape Hyacinths—white and blue. The round-leaved Cardamine, Megaseas, dwarf Rhododendrons, Heaths, Crocuses, Dodecatheons, Daisies, and others to hold aloft the banner of hardy flowers. When the gentler days come, as come they will, we shall look upon them with greater delight as we think of the wild days of the stormy amazonian month.—S. ARNOTT.

HARMFUL AND HARMLESS GARDEN MOTHS—18.

JUST now, when those species of Sallow and Willow which flower in spring are opening the bloom which has been held back by easterly winds and dry weather, it is not unusual for persons to go out and gather it for decorative purposes. Upon visiting a row of these trees or shrubs by day, should it be fine, we are likely to see a numerous gathering of bees and flies refreshing themselves after their winter's sleep. Then, after dark, appear larger representatives of the insect people, stout-bodied moths, mostly of the *Noctua* tribe we are now considering, who come to take their share of the nectar, to strengthen themselves for the work of oviposition. There may be, perchance, a couple of moths on the same spray, not very unlike each other, but yet the history of the two is quite different. One has burst the pupa shell, influenced by the rising temperature, and is taking an early flight; the other appeared on the wing during autumn, and passed the winter in some retreat.

Gardeners frequently come across such moths during winter and spring. Occasionally, no doubt, their proceedings are the cause of some of these insects waking up from their six months' repose; they disturb them in houses and sheds, probably they now and then kill the insects as "suspects." One of these moths is the herald (*Gonoptera libatrix*), which is a visitor to the flowers of spring, but is said to have received its name from the fact of its emergence towards the end of autumn, when it is regarded as a herald of winter. However, the moth very soon settles down, and it has a curious liking for the dwellings of man. I have seen it hunted out of rooms on the supposition that it was a species which would prey on woollen or silken materials. An entomologist once discovered about a dozen of the herald moths in a garden tool house which had been locked up all the winter, and which they had evidently entered by a small opening. The scolloped, or cut, wings are very distinctive; they are downy, as also the thorax, and the general colour greyish-brown, crossed by a bar of bright red, in the centre of which is a small but conspicuous white spot. The caterpillar I have often taken in June; it is thin and velvety, of a deep green hue, with a pale stripe along each side. Unlike most *Noctuas*, it spins a cocoon of fine silk upon a twig when adult.

Returning to our foes of the genus *Agrotis*, we come to a moth

nearly allied to the species named after the Turnip, but of very promiscuous tastes (*A. segetum*), referred to in the last article. This is *A. exclamatoris*, or otherwise the heart and dart. I do not think the insect ever exclaims, but the gardener may, on discovering the mischief done surreptitiously by the caterpillar. The English name is suggested by a couple of marks, nearly black, upon the brown ground of the fore wings. Mr. Newman has pointed out, also, that the erect collar of the thorax resembles a figure of a flying bird. The moth, therefore, cannot be mistaken for its relative, but the caterpillars of the two are scarcely distinguishable, showing the same series of shining spots on the surface of the body, which varies in colour; usually it is some shade of brown.

Commencing to feed early in July, this caterpillar at first feeds above ground on young plants, or on the lower leaves of garden vegetables; about two months later it takes to an underground life, at least during the day, for an examination by night will often show it busily mining heads of Cabbages and Cauliflowers, sharing the spoil with the equally detestable Cabbage moth caterpillar. Right on into autumn it is eating the crowns or roots of Parsnips, Carrots, and Turnips. Probably it eats occasionally through the winter months, changing to a chrysalis in April; its cell is 3 or 4 inches under the earth. When the Lime tree is in blossom the moths may be noticed hovering round its branches soon after sunset.

Then we have another familiar *Agrotis*, which is called the garden dart, *A. nigricans*, a dingy coloured species, the brown slightly tinged with red; there are a couple of pale spots, rather like a half moon in shape, and a blackish streak joining one of them to the base of the upper wing. It is a July moth. The caterpillar resembles others of the genus in habit, feeding from autumn to spring; it is most frequently noticed in May. This caterpillar is of a greenish brown, sometimes it appears rather of a reddish brown, with a shining plate behind the head. It is best distinguished from its relatives by a double white stripe above the feet, and the rows of black warty spots. It is occasionally taken upon low plants about gardens, no doubt, but its favourite food is Clover, and a company of them has been known to entirely strip a field, finishing off upon the banks and hedgerows near. Another common species is the white line dart (*A. Tritici*). Though thus named after Wheat it does not usually feed upon cereals, but eats Cabbages, Onions, and other vegetables in gardens; also it devours some weeds. It is seldom found above ground, chiefly attacking roots or stocks, excepting along the coast of Ireland, where this caterpillar has been taken freely on the Sea Plantain. On the back it is grey, the sides of the body being green without black dots, but there are some narrow stripes; its head is glossy and small. When dug up it at once rolls into a compact ring. The moth is rather of a grey brown, the wing rays pale, with a white line or streak generally conspicuous on the upper edge of the fore wings. It is a quick flier.

There is scarcely need to describe the common yellow underwing (*Tryphæna pronuba*), a moth no gardener can well mistake for another; the orange-yellow under wings, edged with black, are conspicuous; the upper wings vary much. Some specimens are much darker than others, and the markings differ in their number or tint. This moth is fond of introducing itself to public notice—it enters sitting-rooms, concert halls, churches too; and an individual will be seen careering about a good while from light to light, till at length it gets a fatal burn, or dashes off into the open air. One thing in this moth, only noticeable when it is turned over, is a beautiful golden streak beneath the upper wings. On taking a moth into the hand we are astonished at the muscular power the insect possesses. The moth appears in June and July; there is but one annual brood, eggs being laid at night upon a great many garden plants, on which the caterpillars feed from autumn to spring; possibly they are inactive during very cold weather, remaining then under the earth. A few years ago this caterpillar was found in several instances to be attacking *Chrysanthemums*, and, as I am informed, it not only devoured the foliage, but it was also detected while young hidden in the flower heads. Recently, however, I have had no reports of its occurrence upon these favourite plants. When adult this is a good-sized caterpillar, nearly 2 inches long and stout, of varying shades of green and brown, but always shows a double line along the back, and upon each side a row of black spots.

This insect may be killed, or starved, by the application of soot and wood ashes to the soil, also by watering with diluted gas lime, paraffin, or soapy solutions. It has been recommended to employ children in the work of hunting for the moths during their season of flight, because in the day they lurk amongst herbage, or get into grass, and being conspicuous, may be easily captured. Rather less abundant, yet distributed throughout the British islands, is the lesser broad-border (*T. Janthina*) which has been called the handsomest of the *Tryphænas* on account of the rich colouring on the upper wings. The caterpillar does not seem to have been noticed by gardeners, nor is it often discovered by entomologists; it feeds from autumn to May. It has a

velvety brown body, spotted and striped, with a shining head, and has been caught infesting Primroses and Polyanthus. Sometimes the broad-bordered yellow underwing (*T. fimbria*) flies out of a garden hedge in the summer; the caterpillar lives on Birch and Sallow chiefly. —ENTOMOLOGIST.

LAWNS AND ALLIED SUBJECTS.

(Continued from page 276.)

TOP-DRESSING of impoverished lawns may, under some circumstances, be worthy of consideration where more drastic measures previously advocated do not find favour. The operation is simple, inexpensive, and non-laborious; yet in bad cases, although paying for the little time and trouble it entails, it probably does little if anything more. This is mentioned because more than one case has come under notice where too much has been expected from top-dressing, and apparently too little return given. An instance of this was noticed in a garden where the soil is of an unusually tenacious character, and where at all seasonable and unseasonable times a rather heavy roller had been in use for years, resulting in a most unfavourable condition of soil texture. Those are, however, natural conditions where the soil is superimposed upon a bed of gravel, producing a kind of earth hunger, where occasional top-dressings may be advantageously employed.

COMPOST FOR LAWNS.

For the purpose in question a compost sufficient for even distribution over a given area should be prepared during the winter by collecting in a heap old potting soil, especially such as is provided by the turning out of a quantity of well-fed Chrysanthemums, as well as burned vegetable refuse, wood ashes, with any spare leaf mould or peaty matter. To this may again be added any good ordinary garden soil, to make up the probable quantity required. The whole should be stored under cover, or in such a manner that it will be dry for use in the spring, when a half hundredweight of superphosphate of lime, representing about a cubic yard of soil, may be incorporated with it. After several turnings to mix the whole, the concluding operation of passing it through a half-inch sieve will give a well blended and valuable compost for applying to the lawn during a spell of dry weather in early spring, at the rate of an 8-inch potful to the square yard, to be sown by hand. A good rough bush-harrow, made of stout Thorn bushes, weighted sufficiently to be easily drawn by two men, is a capital implement for finishing off the distribution, and may, in fact, take a few turns with advantage prior to applying the top-dressing.

TRIMMING VERGES.

Passing notice may be given to the trimming of verges, an operation performed every year where neatness and order are appreciated. No more suitable time for this work can be chosen than the present, when all the winter's work, comprising any alterations in the pleasure ground, is practically completed. Previous to paring the edges it is necessary that the margins, rendered more or less friable by the action of frost, should be well consolidated by repeated rollings, or even beating with the turf-beater or back of a spade. A uniform depth from the grass to the gravel is essential to a well-finished appearance, and the verge-cutter being held in such a manner as to give a slightly angled face towards the walk, a more durable edge will result than when the cut is made directly vertical, but the slope to the walk should not be very apparent.

The neat workman will, as a preliminary, scrape well back from the grass margin all loose gravel, thus allowing for cleaning up the parings before it is replaced. Care will be taken that the necessary curves, or any deviations from a straight line, will be outlined in good taste. The garden line, which should be sound and free from knots, will at first be lightly laid in the supposed position, following the line of the curves, which on the concave side will require the staying support of small stakes placed sufficiently close to preserve a graceful outline when the line is drawn fairly tight.

At intervals of a few years certain encroachments made upon the verges at either side of the walk will necessitate a reconstruction of the outline; this, in some cases, will entail the labour of piecing the verge on one side only. The simplest and best method of doing this is to set the line 9 inches back on the lawn, following any curves in the walk, and cut down the whole length, then push the turfing-iron under the sod from the walk along the whole face, and draw the liberated strip of turf forward on the walk as far as may be required, the bared strip behind being made good by the insertion of new sods. This method of piecing by insertion, unless an extraordinary depth of margin has to be made up, is infinitely preferable to patching by addition to the face. The opposite edge may then be cut to match, but in certain cases has to be treated similarly. It is a question for judgment.—SYLVA.

(To be continued.)

CHINESE PRIMULAS.

THE Primula family is a very numerous one, and embraces both greenhouse and hardy species. Everyone is familiar with the Auricula, the Primrose, and the Polyanthus, which brighten beds and borders in spring. These are members of the Primula family, and in their season of flowering are perhaps as much appreciated and probably more popular than the less hardy Primulas which require greenhouse cultivation. Chief among the latter stands the Chinese Primula, one of the best of winter and early spring flowering plants for conservatory decoration. Easily raised from seeds in spring and needing no extraordinary skill in its cultivation, it may be had in bloom from September to April. It was introduced from China in 1820, but since then it has been immensely improved in habit, colour, size of blooms, and floriferousness to such an extent that the transformation is marvellous. The highly developed condition which the Primula has reached at the present time has been effected by careful and persistent efforts in improving step by step on previous attainments, and the floricultural world owes much to those who have striven and succeeded in reaching the present perfection.

There are two distinct divisions of the Chinese Primula—namely, single and double, both of which have numerous shades of colour in the flowers. Strictly speaking there are three divisions when the semi-double varieties are included. The latter and the single flowered can be easily raised from seed, but the double varieties require to be propagated by cuttings. An important point in the habit of Chinese Primulas is their dwarf compact growth of foliage, the best grown examples seldom reaching a greater height than 9 or 10 inches, including the flower truss, which should be thrown up amidst but well above the leaves.

Seeds of Primulas are best sown in April and May on the surface of the soil in well-drained 5-inch pots or shallow pans. Loam and leaf soil, the latter predominating, with plenty of silver sand, forms a suitable medium on which to sow the seed, which must be done thinly. Some cover the seed and others do not. If covered, it should only be lightly, using fine soil or sand. In a mild bottom heat, the pot being shaded with glass or paper, the seeds will soon germinate. A bottom heat of 65° is suitable. As the seedlings advance in size prick them out round the edges of 3-inch pots filled with similar compost as recommended for sowing. Three large or four small seedlings may be placed round each pot. Water lightly at first, but sprinkle daily, shading from sun when it is likely to do the young plants harm. They, however, soon strengthen, and when the leaves begin to overlap each other, divide, and pot singly in 3-inch pots, employing a compost consisting of fibrous loam and sweet leaf soil in equal parts, with the addition of a fourth part of thoroughly decomposed manure, a sprinkling of crushed charcoal and silver sand freely intermixed with the whole, in order that the complete porosity of the compost may be insured.

The pots should be quite clean and dry, crocked carefully with a few potsherds, over which place a layer of moist moss or fibrous portions from the compost, which must be moist, but not at all wet, at the time of potting. In separating the young plants it is necessary to be careful, as the leaves frequently adhere one to the other, and the stalks are liable to be snapped. It will also be evident how much easier and safer it is to handle short and sturdy young plants that have previously had light and airy treatment. A tender brittle condition is a characteristic of young plants which have developed in a too warm, moist, shady, and confined position. Crowded plants, too, seem to have a less number of roots, the lack of which is more unfortunate than the size of the plant.

An important point to observe in potting is to sink the plants low enough, so that no part of the stem below the base of the leaves is above the soil when the potting is finished. This steadies the plants, and the buried portion of the stem emits roots. Pot moderately firmly, yet not compressing the soil to an undue extent. Leave the surface level, and slightly below the rim of the pot.

The treatment after potting insures the best results if the plants are kept rather warm and close for a brief period, so that the roots make an early and vigorous start in the fresh soil. When they have done so more air ought to be admitted, as well as all the light possible, without exposure to direct sunshine in the middle of the day during the summer. Water to the roots will only require lightly applying at first, but when growth increases adequate supplies must be given as needed. As the young plants develop, and the roots commence to run round the ball of soil, either an airy shelf in a greenhouse or a position in a cold frame is desirable.

The next potting may be to 5 or 6-inch pots, or 48's and 32's, as some prefer to term them. The drainage must be again ample and perfect, the compost fairly rich, consisting of rather more fibrous loam and a little less leaf soil, with an increased proportion of decayed manure, thoroughly pulverised cow manure being suitable. Sand and charcoal are also essential. As in the previous potting, sink the plants low down, potting firmly. The compost being moist when used, water will not be required for several days; then give a copious supply,

which may probably serve for a week. Keep the frame close the first week, which will induce the plants to root quickly into the fresh compost, and shade from strong sunshine. The base on which the pots stand ought to be fine cinders or ashes, as this material prevents worms, to some extent, finding their way through the drainage to the soil, and insures regular moisture. The plants are best not far from the glass. When well established give air freely and constantly.

During July and August a frame with a northern aspect obviates the necessity of frequent shading; but the position ought not to be one subject to rough winds or shaded otherwise than from the direct rays of the midday sun. After the end of August Primulas are better for full exposure to sunshine with abundance of air. During that month and September there will be frequent occasions when the lights may be drawn completely off the frames, hardening and strengthening the plants for housing in October.—E. D. S.

BULLFINCHES VERSUS CHAFFINCHES AS BUD DESTROYERS.

THE recurrence of complaints regarding bullfinches of damage done by them among fruit buds and seed beds seems founded on a popular mixing up of two distinct birds. The said damage is undoubtedly done by the chaffinch (*Fringilla cælebs*, L.), and not by the bullfinch (*Pyrrhula vulgaris*, syn. *Loxia pyrrhula*, L.), and yet we only hear the bullfinch alluded to in correspondence, while hundreds are reported shot or caught during those depredations. I take notice of birds in gardens, and constantly see chaffinches, but bullfinches never. Is this singular misconception to continue and the misnomer to be perpetuated?—A GARDEN AND BIRD LOVER.

[Thinking the "misconception and misnomer" ought to be proved, we consulted a very experienced fruit grower, and an equally devoted bird lover, on the subject—so devoted that if a doubt could be discovered the bird would have the benefit of it; yet he is constrained to say:—"The chaffinch, a lively and handsome bird of the finch family, very common in Britain, chiefly haunts gardens and shrubberies, hedgerows, and plantations, and its food consists of seeds, and of insects and their larvæ. The latter are the favourite food of this bird, and it does good service in the destruction of them. It is also fond of the sprouting or newly-sprung seeds or plants of Radishes, Turnips, and other small seeds, practically spoiling seed beds and drills of such seedlings, unless prevented. This may be effected by an occasional evening sprinkling with paraffin solution when the seeds 'peep' through the soil. The chaffinch otherwise does no harm, but much good, in gardens, never interfering with fruit buds or fruit crops. It feeds its young mostly on insects, chiefly small caterpillars, the neat and elegant nest being frequently placed in a fruit tree in a garden or orchard.

"The bullfinch has a short, rounded, robust bill, which it uses very effectively for destroying the buds of fruit trees, and also for getting at the seeds of various plants, such as those of the 'Hardhead' (*Centaurea nigra*). Its food consists chiefly of seeds, mostly weeds, and the buds of various trees, but prefers those of the Plum (of which it has its favourite varieties), Gooseberry, and Red or White Currants, less so those of the Pear and Apple. It seldom visits town gardens, the sturdy-billed sparrow taking its place there in destroying buds; but in the country the bullfinches sometimes appear in such numbers during the spring as to ruin the fruit crop in bush and tree plantations. In one season we have known fifty-seven of these very beautiful birds shot by one person. They nest in large hedges or thickets away from the garden or fruit plantation, hence the little good they do in clearing a few soft insects at breeding time is not felt in gardens, or only indirectly."

We have to confess that the record is in close accord with our experience, and we think the great Plum grower of Mentmore, Mr. J. Smith, knows which variety of Plums in the bud state "bully" likes best.]

HABENARIA BONATEA.

I AM sending for your inspection a fairly good example of the somewhat uncommon S. African terrestrial Orchid *Habenaria Bonatea*. Although not particularly fragrant during the day, at night the flowers emit a very dainty yet penetrating odour, suggesting a combination of *Nicotiana affinis* and Tea Rose. An interesting and peculiar characteristic of the flowers is the provision made for their ready impregnation. The green and white flowers, with their prominent spurs, are rendered all the more attractive by the purity of the white and the freedom with which they are produced on the scapes of well cultivated plants, and these are seldom met with outside botanical collections.—JNO. E. JEFFERIES.

[The spike sent by our esteemed correspondent was a fine one,

and the species is very interesting. It has been known to botanists for some considerable time, but is not sufficiently showy for the majority of growers, except those who pride themselves on the botanical treasures that are comprised in their collection. As Mr. Jefferies says, the green and white flowers are pleasingly fragrant in the evening.]

DENDROBIUM NOBILE ASHWORTHIANUM.

IT is probable that no section of the great family of Dendrobiums is more popular than that of *nobile* and its several varieties. Free in flowering, chaste in colour and form, and comparatively easy to grow, they will long remain in the front rank of Orchids. No wonder then a white form should receive great admiration and practical

FIG. 60.—DENDROBIUM NOBILE ASHWORTHIANUM.

appreciation from the Orchid Committee of the Royal Horticultural Society in the form of a first-class certificate. Such was the fate of *D. nobile Ashworthianum* when it was staged by Mr. H. Holbrook, gardener to E. Ashworth, Esq., Harefield Hall, Wilmslow, at the Drill Hall, and of which we give (fig. 60) an illustration. As will be perceived the form is not quite that of the type, but as such it is classed. The sepals and petals are pure white, and slightly twisted. The broad open lip is also of that colour, and has the slightest suffusion of light yellow in place of the familiar blotch.

ODONTOGLOSSUMS.

PERHAPS at no other time of the year is the cool house so gay as now, the number of species of the above genus in flower being very large. It is necessary to visit a large trade or private collection to get an idea of the number of fine forms the genus contains, for every importation of well-known kinds is sure to contain something new in the way of spotting or colouring. The lovely forms of *O. crispum* alone are so varied that to describe half of them would take up many columns, while the many hybrid forms, natural and artificial, are getting a numerous lot.

O. Pescatorei is a species that will always be in demand, the chaste and beautiful flowers so freely produced being second to none. Those with large heavy blotches are more valuable than the white ones, simply, of course, because of their rarity, for they are not more beautiful than the ordinary type if a good form of it is obtained. *O. triumphans*, again, is a splendid species for display, the large bold flowers being a bright golden yellow more or less spotted with brown. It is, perhaps, the most free-flowering of all the cool species, and very easily accommodated. Hardly less so is *O. tripudians*, a rarer kind, often imported with *O. Pescatorei*, which it closely resembles in habit though differing entirely in the colour of the flower.

Between these is the fine natural hybrid *O. excellens*, grand forms of which have recently been exhibited. *O. luteo-purpureum*, too, in its many forms is one of the best and freest, while the smaller and more delicate *O. blandum* is a gem in the cool house just now. *O. Sanderianum* comes very near to, if it is not a variety of, *O. constrictum*, and both are charming when seen in good condition. Equally so is *O. Andersonianum* and the many forms of *O. odoratum* and *O. gloriosum*, while many more might be named that are now flowering.

Enough have been mentioned, however, to show how gay the house may be just now, and a few remarks on management will probably be of more interest than a long string of names. In the first place it is very necessary to see that the plants do not flower before they are really strong enough to bear the strain, and, again, those that are allowed to flower should be relieved of their spikes

directly the pseudo-bulbs show the least sign of distress. If these points are not attended to the greatest care and attention in other ways will be futile, for one season of overflowing will take years of careful growing to make it up, if, indeed, the plant ever recover. It has been the cause of the death of hundreds of good plants.

The atmosphere of the house wherein these plants are grown is an important point, and though when many flowers are open one is tempted to use very little water about the floor for fear of spotting, this must not be carried too far. The whole of the Peruvian and New Grenada *Odontoglossums* like a moisture-laden air, always kept moving by free ventilation. Shade, too, is necessary now for the sake of the flowers as much as the plants themselves, but it is not wise to allow the blinds to remain down too long. If a suitable amount of air is put on the first thing in the morning this will prevent the house getting hot all at once when the sun shines.

Keep increasing the air, so that the temperature rises slowly, and at the same time damp freely every part of the house. Thus the foliage will be kept cool, and until the temperature has risen to 60° or thereabouts, the shading is best off the roof. This, of course, refers to the present time; later, in the summer, it is better to shade much earlier, the whole trouble then being to keep the temperature low enough night or day. Recourse is had to wet mats and other things in addition to the usual shading material, but when the sun is pouring down on the glass at midsummer it is impossible to keep the house as cool as the plants require.

With regard to compost it is quite a mistake to be always loading the roots with compressible material, as peat and moss. If, when top-dressing is in progress, a few pieces of crocks and charcoal were provided the evil is not so pronounced, but instances are repeatedly coming under my notice of plants with their roots embedded in sodden material, simply owing to neglect of this matter. It is not, in fact, a good time now to be pulling cool *Orchids* about at the roots at all. If I had a number of plants in bad order, so bad that the roots were not thriving, I should certainly shift them at any time of the year, but for a general repotting there is no time like the early autumn.

Insects at this time of the year seem especially voracious, and many a grand spike has been ruined by slugs eating it at the bottom. If there is an *Odontoglossum* coming into flower these pests are bound to find it if they are in the house, and a continual watchfulness must be kept up by day among the bases of the bulbs, and in the compost at night when the insects are feeding, this by the aid of a light. Traps made from hollowed-out Potatoes are as good as anything for woodlice and small snails, while cockroaches are destroyed by poisoning with arsenic in the form of beetle paste.—H. R. R.

THE AMARYLLIS.

THE present *Amaryllis*, or *Hippeastrums* as they are now commonly called, are descendants of *vittatum*, *reticulatum*, *aulicum*, *psittacinum*, and other species, mostly natives of South America, where, I am informed, they grow naturally in shady copses, woodlands, and on the banks of rivers, and when in flower they form a gorgeous display. By constant and careful hybridising, however, the flowers of the original species have been vastly improved upon, both in size, brightness of coloration, and the general quality of the flowers, so at the present time it would indeed be a retrograde step for any cultivator to go back to the original species.

In dealing with the cultivation of these handsome and gorgeous bulbous plants, this paper will be divided into the following different headings:—Raising of Seedlings, Treatment of Flowering Bulbs, Hybridising, Insect Pests, and General Remarks.

RAISING SEEDLINGS.

Amaryllis are very easily raised from seeds, which in all cases should be sown as soon as ripe, and presuming the plants flower in March and April, the seed will be ripe before the end of May. The most suitable soil is composed of an equal mixture of light fibrous loam and leaf mould, with the addition of a good portion of silver sand, and a sprinkling of wood ashes. Drain the pots or pans thoroughly, and cover the crocks with moss to prevent the soil being washed into the drainage. The seeds may be covered about $\frac{1}{8}$ of an inch with fine sandy soil, then watered with tepid water. Plunge the receptacles in bottom heat of about 75° to 80°, place a sheet of glass over each, and shade from bright sunshine. In about three weeks the seedlings will appear, when the glass may be gradually removed, and by the time the young plants are producing their second leaves they may be pricked off an inch asunder in either shallow boxes or pans, using a little more loam in the compost. They should again be plunged into bottom heat until fairly growing, when they may be placed on the stages of an ordinary stove, where they can be conveniently shaded during very bright sunshine, always keeping them where a genial, moist atmosphere is maintained.

By the autumn the plants will be fairly established, and must be encouraged to make strong, sturdy growth, and when the days begin to shorten place them in the lightest part of the plant stove for wintering. Keep them growing all through the winter, using care with the water-

pot, as if over-watered many roots will perish, and the foliage will be lost at a time when it is most required. The winter temperature for the young plants may range from 60° to 65° by night, with a rise of 5° or so by day, always taking advantage of a sunny day to dew them slightly.

As soon as the days begin to lengthen in spring increase the temperature, when growth will be more rapid, and a further shift will be required. If only a few plants are grown they may be potted, using well drained pots according to the size of the bulbs and roots. A little more substantial soil may be used. We find light fibrous loam, three parts to one part leaf mould, with a fair amount of sand, wood ashes, and a sprinkling of soot, to produce satisfactory results, although where the soil is of a heavy or retentive nature the admixture of fibrous peat and powdered charcoal would doubtless be beneficial. Efficient drainage is always essential, and after potting it is advisable to replunge in bottom heat of about 70°. Should the soil be fairly moist at potting time no water will be required until the roots begin to take hold of the new compost; but a moist atmosphere must be maintained by syringing on all favourable occasions and damping the floors and walls. At this potting the leaves of the plants are tender, so in order to prevent their being broken it is better to stake them.

Where many plants are raised it is better to have a bed in one of the houses, preferably over the hot-water pipes, making up the soil about 4 to 5 inches in depth, and plant out the young bulbs 3 or 4 inches apart, and otherwise treat in the same way as the potted plants. Shade during very bright weather, and when the bed is well filled with roots commence feeding by giving soot water, liquid manure made from sheep's droppings (always in a weak state), and occasionally a slight dressing of Clay's, Standen's, or any other quick acting, stimulating manure. By keeping the plants in a constantly growing condition for about sixteen months they will have made fine bulbs, and as autumn comes on they may be gradually brought to rest by inuring to sunlight, withholding water, and reducing the temperature. These points must be carried out gradually, it often being three months before the foliage all dies down. Those that are in pots may then be placed in their winter quarters on shelves in the greenhouse, and those planted out will be a regular network of roots, which may be torn into convenient sized clumps and wintered on the border of a vinery which is at rest.

FLOWERING BULBS.

A few of the seedlings will now have attained flowering size, and all may be treated as flowering plants. We will assume that when the bulbs are placed in their winter quarters they are devoid of all foliage, and unless they get quite dust dry receive no water at all through the winter months, any greenhouse where frost is excluded being suitable for wintering them. Early in the new year signs of activity begin to show themselves, flower spikes generally being the harbingers of growth. The bulbs should be firm and hard, and it sometimes seems impossible for the spikes to push their way through.

Presuming we have a stock of flowering bulbs, which the previous season were established in 6-inch pots, it is unnecessary to repot them; simply turn them out, rectify the drainage, and place them back again, shaking off any loose soil, and top-dress with fairly good rich soil. Previously prepare a place for them in an intermediate house, where a bottom heat of about 60° can be maintained. This may be done either by means of hot-water pipes or a bed of prepared leaves and stable litter. If the latter course is preferred, the materials should have been mixed some time previously out of doors, and occasionally turned in order to get off the rank ammonia. We find it simpler to utilise the beds in a Melon house, where hot water is used for supplying the bottom heat, the pit's refuse being filled up with cocoa-nut fibre refuse, and the pots plunged therein.

The temperature of the house should be kept about 50° to 55° at night, with a slight rise by day. Do not water the plants until growth has fairly commenced, but keep the house moist by syringing and damping. Give air on all favourable occasions, and as the plants grow afford water at the roots as they require it, and occasionally a little weak manure water, as before advised.

Now let us turn back to the seedling bulbs that have rested. They will require potting, with any flowering bulbs that have not been repotted for a couple of years. The same soil as used at the previous potting will be suitable, and pots 6 inches in diameter are generally large enough for the biggest bulbs. Shake all the old soil from the roots, and pot firmly, then plunge them in the same place as recommended for the plants that were top-dressed. Newly potted plants require no water at the roots for some time, as the damping and syringing is sufficient for them. While in flower the house is kept fairly cool, say about 50°, plenty of air admitted, and always shaded during sunshine.

After blooming the house is required for the cultivation of Melons, when all the plants are placed in a heated pit, shaded during sunshine, and kept at a moist growing temperature of 65° to 75° until about the end of August. Water is afforded as required, and an occasional sprinkling of any quick-acting plant food, also a little soot and liquid manure in a weak state. Towards the end of August they are gradually brought to rest as before advised for the young plants, and when the foliage has died down are placed in their winter quarters until required for starting again.

HYBRIDISING.

This is probably the most important feature in the cultivation of the *Amaryllis*. Not that there is the slightest difficulty in raising any

number of progeny, but in the fact of using suitable varieties for cross-breeding. For instance you may take the pollen from a good dark variety and use it on the fine light one, or *vice versa*, but with what result? You would naturally expect beautifully striped varieties, but would be disappointed, although occasionally you might get a good striped one. The majority, however, would do credit to neither parent. If improved flowers are wanted select two good darks, two good lights, or two good striped, carefully remove the pollen from the flowers that are to be operated on, fertilise with the required pollen, and the results will be both satisfactory and interesting. While speaking of the seed-bearing plants, it is best if possible to keep them plunged until the seed is ripe, as the ripening takes a great deal out of them. Do not leave more than one pod to a plant if it can be avoided. A pod contains usually from fifty to eighty seeds, although I once had an Empress of India with over 100 ripe seeds in it, and from 90 to 95 per cent. of freshly sown home grown seeds will germinate under favourable conditions.

INSECT PESTS.

Bug is a very bad thing to deal with, as when the leaves die down it hibernates in the soil and in the scales of the bulbs. Where any has been detected during the growing period remove all that can be reached, and in winter remove all loose scales, and wash with XL-All insecticide, rubbing it well into the scaly portion of the bulbs with a small painter's brush. Brown scale is also troublesome at times, and must be washed off with an improved insecticide whenever detected. It is always best to keep these pests thoroughly in check, as any handling of the plants results in some of the leaves being broken when they are most required. Black thrips are also troublesome, but fumigating with XL-All vaporiser speedily puts an end to them. Slugs are very fond of the flower spikes when they first appear. They may be trapped with Lettuce leaves, Orange peel, or bran, and caught at night time, or where slugs abound many spikes will be devoured.

GENERAL REMARKS.

It is six or seven years since we took up the cultivation of this handsome class of flowers. We had then a few seedlings which had attained flowering size, and a few bulbs of leading varieties were purchased from a noted firm. From these and purchasing seed our present stock has been worked up, and we have a good supply of flowers from the latter part of February until the end of April. They are always much admired by visitors to the gardens, and are most useful for decorations in the house in a variety of ways. We have found their cultivation much easier and simpler since devoting a house entirely to them; when we had only a few they seemed to be always in the way and wanted moving. Some people talk of flowering them two and three times yearly. They are welcome to do it. We are quite satisfied with their blooming once. Others keep them moist always, and make them semi-evergreen; but they are not so satisfactory as when thoroughly rested in winter, neither are they so good to rid of insect pests.

Size of blooms seems now to be one of the chief requirements in a high-class flower, and blooms with green centres are denounced. A good bloom should be, if a self, of bright colour; sepals and petals as nearly equal as possible, large in size, and quite round. In the striped ones the markings should be clear and distinct.—W. J. IRELAND.

HARDY SHRUBS AND PLANTS IN TOWNS.

(Concluded from page 286.)

AMONGST climbing plants the Virginian Creeper, which belongs to the Vine tribe, stands well to the front as an ornamental plant. In autumn, with its beautiful tinted leaves close carpet-like growth against a wall, it stands unsurpassed in neatness and beauty. This plant does not climb by twisting like the Convolvulus and Scarlet Runner, or by aerial roots like the Ivy, or by ordinary tendrils like Peas, but by those which are furnished with suckers at their ends, and by them adhere to their supports, whether boards, trees, or walls, the latter being far the best. Another trailing plant which may be used as a climber in towns is called the Tea Tree, Box Thorn, Lycium barbarum, or the Duke of Argyle's Tea Tree. It gained the latter name by its leaves being used as a substitute for China Tea, about 100 years ago by the then Duke of Argyle. There may be a little difficulty in inducing it to grow at first, but once let it get established far more difficulty will be experienced in removing it. Although the words Thorn, Box, and Tea are so much used in its popular names, it has no affinity with any of them, but belongs to the Nightshade family, and is a native of the countries bordering on the Mediterranean.

Of the common White Jasmine (*Jasminum officinale*) Lindley says, "The pride of the cottagers, and the envy of the citizen, within whose smoky streets no arts can make it flourish." This, however, is not so; it grows very well in Spring Street and other places in Hull. It is a native of the mountains in India, whence years ago it found its way to the Persians and Arabs, who called it Yasmeeen, and thence passed to Europe, and was known in this country about the middle of the sixteenth century. The flowers yield the oil of Jasmine, but not by distillation. It is obtained through the agency of oil of Ben, which is afforded by the seeds of *Moringa aptera*, and this in cotton wool extracts the fragrance of Jasmine and other flowers placed on it which have not sufficient basis in themselves to fix their scent. This Jasmine affords a good example of unequally pinnated leaves.

Clematis vitalba, popularly called "Traveller's Joy," because it beautifies the roadside hedges; "Virgin's Bower," because it often covers arbours and summer houses; "Old Man's Beard," alluding to the silky elongated styles; "Smoke Wood," because the boys sometimes use the dry hollow stems for a cheap smoke, stands at the head of the list for hardihood, rapidity of growth, defiance of smoke, dust, and crowded places. It will grow in sunshine and out of it, but rather objects to winds, which often break off the ends of the shoots and so retard its growth. I have seen it growing well in a back yard, where it had been planted in a hole cut through a flag-stone. It soon covered the walls, then coolly climbed over into the next yard and filled it, and the next and next too. I have seen it growing vigorously in a passage. True its flowers are not very grand, but it produces an abundance of green leaves, and will cover very quickly a great extent of walls or fences with a little assistance in securing the growths. What more can be expected in a town plant? It does not climb by twisting round, or by aerial roots or tendrils, but uses the stems of its leaves for the purpose. It just turns the entire leaf once round anything it can grasp, taking a strong, firm grip of it, finally placing the leaf in its proper position, and a very simple and effectual mode it is. Another peculiarity of this plant is the growth of the pistil after fertilisation has taken place, imparting a fluffy appearance.

Now for a few words about herbaceous plants. The good old *Iris germanica* grows and flowers well in town gardens. This plant is said to have been introduced to this country from Germany in 1573. There are a very large number of varieties, all very beautiful, and deservedly becoming general favourites. This *Iris*, commonly called the blue *Iris*, or *Fleur de Luce*, was the emblem of the French kings.

Another plant that succeeds admirably is the London Pride (*Saxifraga umbrosa*), also known in some places as "None so Pretty," which name has been corrupted into "Nancy Pretty." Smith, writing of this plant, says it is a pretty rosulate-leaved herb, a native of this country and Ireland. It appears to have been first brought into special notice as a garden plant by George London, who was, between the years 1681 and 1717, a celebrated nurseryman and gardener, and with his partner, Mr. Wise, held more than 100 acres of ground known as the Brompton Park Nursery, now occupied by the South Kensington Museum and the Albert Hall. What a change!

Another excellent town plant is found in the Evening Primrose (*Oenothera biennis*). It is called Evening Primrose because its flowers open about 6 or 7 P.M., and are of a pale yellow colour, smelling like a Primrose. It has no botanical affinity with Primroses, but belongs to the same order as Fuchsias and Willow Herbs. Some people consider it to be a doubtful native of this country, while others believe it to be indigenous.

None of the Heaths or their allies will grow with me, but nearly all hardy bulbs succeed, such as Tulips, Hyacinths, Lilies, Snowdrops, Bluebells, and Narcissus, though the sparrows often eat the flowers of the latter. Antirrhinums grow well, as do Wallflowers and Lily of the Valley. This plant is a native of Britain and other parts of Europe, being generally found in shady places in woods, and as commonly cultivated in gardens. The Foxglove may be added. This is one of our showiest native plants, generally found growing on the margins of and the open parts of woods, where it is conspicuous by its tall spike of handsome flowers. Many garden varieties are very beautiful.

There is a small creeping or trailing plant, called by the learned *Lysimachia nummularia*, popularly Loosetrife, Moneywort, Twopenny Grass, Herb Twopence, and about London Creeping Jenny. This much-named plant should, I think, be much more grown than it is. I often see it in vases, hanging gracefully down, studded with its yellow flowers, and think I must make more use of it.

Dielytra formosa, Michaelmas Daisies, *Epilobium angustifolium*, and *E. hirsutum* must not be forgotten as good growers under adverse conditions, and I therefore regard them as useful plants. *Calystegia pubescens*, the American Bell Blind, and *Convolvulus sepium*, the large white-flowered Bindweed, make two serviceable climbers in small places, where their roots, or rather underground stems, are prevented from spreading too far, and so causing trouble. I think everyone must have seen the giant Siberian Cow Parsnip (*Heracleum giganteum*). It often attains the height 10 or 12 feet. I believe it is the tallest plant in all the order Umbelliferae. It is a stately plant, and will grow almost anywhere. Lupins also do well. In Germany and in some parts of this country the yellow Lupin, *L. luteus*, is cultivated for ploughing in as manure.

Another old vigorous plant should be mentioned, I mean the common Tansy. Much cannot be said about the beauty of its flowers, but the leaves are finely cut and curled, and are of a pleasing green. This plant will, like the *Heracleum*, grow almost anywhere, and is credited with many virtues, besides yielding tannic acid.

I have named a few shrubs and plants which I have found to grow under adverse conditions. I hope there are many more plants that will grow in towns, and this is, I think, a proper time to make a special study of them; also I would hope that many towns will gradually be made more suitable for plants by the provision of wider streets and open squares where the sun can shine on every habitation, and where trees, shrubs, plants and flowers will flourish, purifying the air, beautifying the scene, and giving pleasure to all who see them. Will it not, then, follow that dwellers with such surroundings will have better health, live happier lives, and have better reason than now to say, "There is no place like home!"—A. E. PEAKE.—(Read at a meeting of the Hesse Gardeners' Mutual Improvement Society.)

WEATHER IN LONDON.—In our last issue we had to tell of wintry storms of snow and rain, but since then there has been a return to the spring-like weather. Scarcely any rain has fallen during the week, and on most days the sun has shone with great brilliancy and power. One or two nights have been frosty, while the wind has occasionally felt rather keen. At the time of going to press on Wednesday it was bright and warm.

— WEATHER IN THE NORTH.—The last two days of March were variable, although pleasant on the whole, with 6° of frost on the 31st. April opened with a very slight frost, and one of the finest days of the season. A rather squally wind and heavy showers followed on Saturday and Sunday, and Monday was rather cold, but the evening somewhat milder. On the morning of Tuesday, which was bright and fine, 6° of frost were recorded.—B. D., *S. Perthshire*.

— ADMISSION TO KEW GARDENS.—Mr. Akers-Douglas, in response to a question in the House of Commons on Monday, said he had decided to admit the public to Kew Gardens (not including the plant houses) at an earlier hour than noon on week days in the ensuing months of June, July, August, and September. He should thereby be in a better position to judge of the extent of the demand by the general public for the earlier opening. There were many details involved in the proposal, into which he was having an inquiry made, and he hoped to give further information in a few weeks' time. He hoped that the Queen's Cottage grounds might be formally added to the gardens about the 1st of June, but he could not absolutely bind himself as to date.

— THE AMARYLLIS.—For a number of years Mr. W. J. Ireland, gardener to J. Wakefield, Esq., Sedgwick House, near Kendal, has devoted considerable attention to cross fertilisation and raising improved forms of this gorgeous plant. On the invitation of the Bradford Paxton Society Mr. Ireland read an interesting and practical paper at the bi-monthly meeting of the Society on the 26th ult. The essayist exhibited upwards of thirty cut blooms of high-class named varieties, and several splendid seedlings raised at Sedgwick. The self-coloured varieties were especially conspicuous for enormous size and brilliance of colour. One of the best of this class received the Society's certificate of merit, and was at once named the Bradford Paxton Society by Mr. Ireland in return for the compliment. The substance of this valuable paper will be found on page 300.

— ISLE OF WIGHT.—The Isle of Wight Horticultural Improvement Association held its second annual show of Daffodils and spring flowers at Shanklin on Saturday last. Mrs. White-Popham, who was introduced by Dr. J. Groves (Chairman of the Association), opened the exhibition with a few appropriate remarks. Amongst the principal exhibitors (the exhibits were non-competitive) were Messrs. Barr & Sons, London, with nearly two hundred vases of Daffodils. This exhibit was much appreciated, and fully deserved the Association certificate for cultural merit. First-class certificates were also given to each of the following varieties—Duchess of Westminster, M. J. Berkeley, and Barri conspicuus. Mr. John Gell, Home Farm, St. Lawrence, staged a collection of Narcissi which fully merited the award of certificate for cultural merit. Mr. F. Woods, Steephill Castle, Ventnor, exhibited well grown Cinerarias, which received the Association certificate for cultural merit. Mr. W. H. Jobling, Spring Hill, East Cowes, exhibited a miscellaneous collection of hardy cut blooms and several fine pots of the Blue Primrose. It fully deserved the Association certificate for cultural merit. Mr. J. H. Silsbury exhibited a collection of Daffodils which received the certificate for cultural merit. Amongst other exhibits which added to the interest of the show, which was visited by over a thousand people (admission free), were Palms and Dracænas from Mr. F. Silsbury, Clarendon Lodge, Shanklin; a miscellaneous collection of pot plants, effectively arranged, from Mr. C. H. Snook, Westhill, Shanklin; cut blooms of Tulips from Mr. J. H. Perkin, Los Altos, Sandown; blooms of seedling Amaryllis and fine spikes of *Iris fimbriata* from Mr. W. Tribbick, F.R.H.S., Brooke House, Brooke; and floral decorations by Mrs. A. Carter, Rosendale, Shanklin.

— ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, April 12th, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. A lecture on "Blight and Blessing," illustrated by lantern slides, will be given by Mr. F. Enock, F.L.S., at three o'clock.

— STATION NURSERIES, HORSHAM.—We are requested to state that Mr. Riley Scott, for upwards of twenty years gardener and steward to Miss Foster, The Holme, Regent's Park, and Oakover, Ticehurst, Sussex, has purchased this business. We wish Mr. Scott, who is well known as a constant exhibitor at the shows of the Royal Botanic Society, every success in his new venture.

— CUCUMBER EVERY DAY.—We learn that the new Cucumber Every Day, raised by Mr. Owen Thomas of the Royal Gardens, Windsor, and exhibited by him at the Royal Horticultural Society's meetings on December 14th, February 4th, and March 4th, will be sent out next year as a novelty by Messrs. Sutton & Sons of Reading. On February 4th this variety received an award of merit, and on March 4th the Fruit Committee thought so highly of it that a first-class certificate was awarded.

— DORONICUM PLANTAGINEUM.—Among the early flowering plants now showing themselves in the gardens is the Plantain Leopard's Bane, which is always welcomed as being the forerunner of many bright flowers. As clumps along the borders the plants are highly effective, and will last in bloom for some weeks, while for indoor decoration this *Doronicum* has no superior in the early spring. The long footstalks and yellow starlike flowers are well suited for furnishing light vases, and though the flower is old and well known it is nevertheless welcomed with a fresh interest as each spring rolls round.—H.

— BIRMINGHAM GARDENERS' ASSOCIATION.—The final fortnightly meeting of the winter session took place on the 4th inst., Mr. W. B. Latham presiding over a very good attendance of the members, when Mr. E. J. Mustin, gardener to A. F. Bird, Esq., The Firs, Moseley, Birmingham, read a practical paper on the cultivation of the herbaceous *Calceolaria*, accompanied by a robust specimen in a 10-inch pot as illustrative of the system of culture that he has proved to be so successful. An instructive discussion followed the essay, and a hearty vote of thanks was accorded to the essayist. Messrs. C. R. Bick and Walter Jones exhibited stands of cut blooms of fine Cinerarias, and not the least interesting feature was a flower of the quaint and sombre-looking Chalcædonian *Iris Susiana*—known also as the Widow, the Mourning, the Sad, and the Guinea Fowl *Iris*—shown by Mr. W. Gardiner, obtained with a consignment of other cut flowers from the South of France. The flower had been kept for over a week in a room, and this, combined with the fact of the time in transit from abroad, goes far to prove the durability of the flower in a cut state.

— MR. PETER BARR, V.M.H., AND HIS TRAVELS.—For some years it has been the custom of the founder of the well-known and highly reputable firm of Messrs. Barr & Sons, King Street, Covent Garden, to spend his summers in different parts of the Continent of Europe. His quest originally was for new forms of *Narcissus* for enriching the remarkable collection at Long Ditton, and the great bulbarian eventually became known as the "Daffodil King." More recently, however, he seems to have travelled for seeing the sights and studying the manners and customs of the people, not in the cities alone, but also in the rural districts of the countries which he visited, Spain having been one of his happy hunting grounds. Mr. Barr has just commenced an extended tour. He was booked to sail on Tuesday last by the ss. "Scythia" from Liverpool to Boston, U.S.A., with the intention of passing from there to Vermont, Middleton, and New York, thence to Philadelphia, Baltimore, and Washington, doubling back to New York. He designs seeing what he can in Canada, crossing the Niagara into the States again, visiting Buffalo, Cleveland, Chicago, Milwaukee, and other places. Then he goes to Salt Lake City to see the Mormons, from thence to California and on to Vancouver, there shipping for Japan, China, New Zealand, and Australia, returning by the Cape of Good Hope in about two years. Such is the plan and programme. It is sufficiently comprehensive, one would think, even for a much younger man, though few young men are more active, physically and mentally, than the energetic explorer, and it is hoped that nothing will occur to impede his progress. Mr. Barr has departed with the best wishes of a host of friends, who will be glad to see him home again. He was chosen as one of the sixty recipients of the Victoria Medal of Honour in recognition of his unwearied efforts and success as a pioneer in the improvement and popularisation of the *Narcissus* mainly, and other flowers on which he concentrated his attention. The business of the firm has long been conducted by his diligent and competent sons.

— **GARDEN CHEMISTRY.**—One of the best scientific and practical gardeners of the day writes:—"What an excellent little book is 'Garden Chemistry' by Mr. Cousins. I have been reading it with the keenest relish. It is a long way ahead of all other treatises dealing with this subject, and is absolutely free from a suspicion of trade influence, which mars several chemistry manuals."

— **ASSAULT ON MR. J. DEACON.**—Two men were remanded at Birmingham on Monday on a charge of assault on the Right Hon. J. Chamberlain's head gardener at Highbury. On Friday night the men were discovered in the garden, and afterwards made an attack on the lodge in which the gardener, Mr. John Deacon, lived, smashing windows and doing a considerable amount of damage.

— **HYBRIDISATION AND CROSS-FERTILISATION.**—These terms are not very clearly defined even by the best botanists; that is to say, the line which separates them is not a hard and fast one. Some say that the union of different varieties of the same species is hybridisation, while others term it cross-fertilisation. It is on this point we find botanists differ. There is, however, no difference of opinion as to the term hybridisation when a union is effected between two distinct species.—E. D. S.

— **TEMPERATURES REVERSED.**—An authority on the subject says that up to the present the annual march of temperature this year has been all in the wrong direction. According to rule, February should, of course, be warmer than January, and March warmer still. This year an abnormally mild January was followed by a colder February, and by a still colder March. The decline is not likely to go on much longer, and it would therefore be scarcely safe to predict good skating in July. It is, however, seldom that the ordinary conditions are so completely reversed as they have been this year. In London the mean temperature of March was about half a degree lower than in February, and nearly 3° lower than in January, the month being the coldest March we have had since 1892. The coldest of the past five-and-twenty years occurred in 1883, while the warmest occurred, singularly enough, in the year immediately preceding it. In March, 1883, the mean temperature in London was not much above 37°, while in 1882 it was exactly 47°—a difference between the two of nearly 10°.

— **HESSLE GARDENERS' SOCIETY.**—There was a large attendance of members present at the last meeting on the syllabus, which was held in the Parish Hall on Tuesday, March 29th, when a general review of the past session was taken and the prize essays read. This session has been, in every respect the most successful the Society has had, and hearty votes of thanks were given to those members who had filled the various offices. Medals were won by Mr. Geo. Picker for fruit, and by Mr. J. T. Barker and Mr. Blakey for plants. The essay competition was divided into two classes, one for foremen and journeymen over eighteen years of age, the subject being "The Management of Stokeholes and Boilers;" and for those eighteen years of age or under the subject was "A Year's Management of the Potting-shed and Tool-house." Seven competed in the former class, and the prizewinners were:—First, Mr. J. F. Donoughue, Tranby Croft Gardens; second, Mr. Geo. Giles, Hesslewood Gardens. Mr. M. Skinner, Bishop Burton Hall Gardens, was placed third. In the junior class the first prize was awarded to Mr. C. Hollingsworth, Cliff House Gardens; second to Mr. G. Mason, West Hill Gardens; and third to Mr. Geo. Hardy, Hesslewood Gardens. Messrs. Geo. Gordon, and H. J. Clayton were the adjudicators.—G. W. G.

— **TORQUAY GARDENERS' ASSOCIATION.**—From time to time we have inserted notes relative to the meetings of this Society, and we now have the report and financial statement that were presented at the annual meeting held on the 1st inst. The Committee is evidently well satisfied with the state of affairs, as is only reasonable when it is noted how successful the meetings have been, and also that the balance in hand is larger than it was a year ago. After this and other business had been settled satisfactorily, the Hon. Secretary, Mr. F. C. Smale, on behalf of the members, presented the President with a beautifully illuminated address in a massive gilt frame, surmounted by a monogram (R. H. R.). The supporting easel was included in the presentation. The exquisitely executed work in the address was from the hand of Mr. A. Shelly, one of the Vice-Presidents, who kindly gave his services. Mr. Shelly also received a souvenir of the occasion from the members. The address was signed by 133 members, and ran as follows—"To Robert Hamilton Ramsey, Esq., M.D., C.M. We, the undersigned members of the Torquay District Gardeners' Association, desire to present to you this address as a token of our personal esteem and regard, and in acknowledgment and appreciation of the invaluable services rendered by you to the Association as President."

— **GENTLE SPRING.**—Those are very charming lines that close your leading article on Spring (page 274), and I am rather more disposed to quote "Punch" on the same theme, which possibly are bad enough to be good enough for insertion:—

"Come, gentle Spring! ethereal mildness come!"
Oh, Thompson! void alike of rhyme and reason!
How canst thou thus unhappy mortals hum?
There's no such season!

Dean Mansell used to say that if March "went out as a lamb" it was indisputably "cold lamb." Certainly this year it has gone out "like a madman;" its terrible three-days blizzard, and accompanying loss of life, will not soon be forgotten.—A. C.

— **READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—Mr. W. H. Lees of The Gardens, Trent Park, New Barnet, read a paper on "Profitable Orchids" before the members of the above Association on Monday evening, Mr. C. B. Stevens presiding. The formal business having been transacted, and a sum of £5 5s. been voted to the special fund raised by the Reading Horticultural Society, the President called upon Mr. Lees to give his paper. In introducing his subject the essayist said that it was not his intention to treat the subject from a market grower's point of view, as the title seemed to imply, but from that of the private gardener, dealing with those varieties most suitable for cutting and decorative purposes. The general routine of the cultivation was briefly dealt with under the following headings:—Ventilation, Heating, Staging, Watering, Manuring, Potting, Compost, Insects and Fumigating. An interesting discussion ensued. A splendid exhibit of Orchids was made, which added greatly to the interest of the meeting and helped to illustrate many of the remarks made by the speaker. A hearty vote of thanks was passed to Mr. Lees and to those members who had been the means of bringing together such a beautiful collection of flowers.

— **THE NURSERYMEN, MARKET GARDENERS', AND GENERAL HAILSTORM INSURANCE ASSOCIATION.**—THREE GOOD P's.—Mr. Alex. James Monro, Secretary, 1 and 2, King Street, Covent Garden, places in condensed form the growth of this useful Corporation. As we published the report on page 287, last week, we can now only indicate the position in 1895-6 and in 1897-8. In the period first named, the premier income was, in round figures, £681; at the end of the financial year just closed, £1360—a gain of more than 100 per cent. During 1895-6 the policies in force numbered 235; square feet of glass insured, 10,408,161; value, £132,215. During 1897-8 the policies increased to 550; glass insured, 20,098,104 square feet; value, £263,590. Claims paid in 1895-6, £283; in 1897-8, £1532—all within six days of the storms occurring. Mr. Monro might not inappropriately head his prospectus the three P's—Prudence, Progress, and Promptitude—prudence in insuring; progress in business; promptitude in payment. Mr. Monro evidently thinks there is another not very bad P—Publicity, and we have pleasure in giving him a friendly advertisement for the good of the cause. If he wants more of this "P," he must Patter out. Mr. Harry J. Veitch is Chairman of the Corporation.

— **"BLACKS" IN POTATOES.**—Is not the dictum of the writer on this topic in last week's issue (page 276) rather strained when he avers that "worse Potatoes were never known within the past fifty years than the present day varieties, as grown and placed on the market?" Perhaps I might ask, Is it not untrue? Because in some districts Potatoes may be indifferent in quality, it far from follows that they are bad everywhere, and indeed they are not so. We should have had just as good Potatoes during the present season as at any time, had we not had to suffer last summer from a severe attack of the Potato fungus. Even in spite of that, what tubers were sound have given little relatively to complain of. But we cannot overlook, in relation to tuber quality, the grave harm that is done when the foliage is destroyed fully a month or six weeks before the tubers are matured. There is no cause, in my estimation, so productive of that discolouration of the tuber when cooked, which the writer terms "blacks," as is this early denudation of leafage. There may be defects in the soil undoubtedly, especially absence of lime, for that is a valuable constituent in the production of starchy matter in the tubers; but nine-tenths of the varied soils in which Potatoes are grown do produce good tubers when the tops are not early destroyed by the disease. The value of spraying with Bordeaux mixture there can be no doubt is not so much the protection of the tubers from disease, as in maintaining the foliage some few weeks longer in a green vigorous condition, and thus enabling it to manufacture starch granules for tuber requirements at the most important period of the tuber's life—that is, just as it is becoming matured or ripened. This phase of the matter demands the fullest consideration.—A. D.

THE YELLOW PROVENCE ROSE.

"PRACTICE" asks about this Rose, and thinks it might be either Persian Yellow or Harrisoni. I turn to my dear old "Rivers" of 1863, the first book on Roses I ever bought, and read as follows:—"The Double Yellow Rose (*Rosa sulphurea*).—It was brought here from Constantinople toward the end of the sixteenth century. It is a native of the Levant, and said never to have been seen in a wild state bearing single flowers. As yet we have but two Roses in this division—the Double Yellow, or Yellow Provence, with large, globular, and very double bright yellow flowers, and the Dwarf Double Yellow, both excessively shy of producing full-blown flowers, though they grow in any moderately good soil with great abundance." I have grown it with some success, and budded it on the Briar; but it is very easy to lose. A very fine specimen grows, or did grow, in great perfection at Burghley, near Stamford town. Exhibitors in the eighties will remember the grand heaps of these Roses which Mr. Webb of Calcot, near Reading, used to exhibit. His Maréchal Niels from the same nut garden were also marvels of colour. This Rose is well worth endeavouring to grow, and is as good a yellow as the two mentioned by "Practice." There is not a yellow Tea Rose which can come near it for depth of golden colour.

I am aware that high authorities identify it with Harrisoni. In my experience it is even a deeper yellow, and of far more solid buds—so solid, indeed, that sometimes half the blooms will not open.

Rivers writes of Harrisoni also, and as follows:—"Rosa Harrisoni is also a double yellow Rose, said to have been raised from seed in America, and sent from thence to this country. This has proved a pretty yellow Rose; its flowers before expansion are globular, but a hot sun makes them expand and lose much of their beauty."—A. C.

THE "GOLD MEDAL" ROSES OF THE NATIONAL ROSE SOCIETY.

THE National Rose Society (founded in 1876), finding that so many inferior Roses were being sent out as new and distinct from existing varieties, all of which were invariably described in the most glowing terms, decided to offer gold medals for any new seedling Roses or distinct sports that were considered of sufficient merit by the judges. Unlike the majority of classes, which are judged by three members, this important class has frequently been judged by from seven to ten or twelve picked judges. To win under these circumstances is a safe test that the novelty is distinct and of genuine merit. In order that the judges may be able to form a better opinion, not only are three blooms to be staged, but a plant from the open ground must be shown at the same time. Thus we not only see the bloom, but can judge of the growth as well. I think the last point of great importance, especially so now that we have so many grand Roses in both habit and flower. It was in 1883 that this class was instituted, and the first gold medal was secured by the late Mr. Henry Bennett of Shepperton.

HER MAJESTY.—This is one of the finest H. Perpetuals we have. We have the pedigree of this grand Rose given as a cross between Mabel Morrison and Canari, and it may seem almost incredible to many that two dwarf Roses should have produced one of such vigour and robustness as Her Majesty. But if we look at other seedlings we find many cases wherein changes play a most surprising part. I do not intend to go into this now, but I do think Her Majesty, as a cross between a H. Perpetual and Tea-scented Rose, should have been classed among the Hybrid Teas. We find evidence of its Tea-scented blood in the foliage. Her Majesty is one of the largest Roses we have, and when caught young has no suspicion of coarseness. More than once it has gained the N.R.S.'s silver medal as the best H. Perpetual or H. Tea in the whole of the large exhibitions of that Society. The description of "pale rose" only does not do this Rose justice. I would rather describe it as a beautifully clear and bright satiny rose. It should be cultivated upon the Briar stock, and comes very good on "cut-backs" and plants well established.

MRS. JOHN LAING.—Mr. H. Bennett, in 1885, showed this variety, which is one of the most useful, reliable, and distinct Hybrid Perpetuals grown. It would indeed be difficult to say too much in favour of it, which, like most of those gaining the gold medal, has also secured the silver medal as the best of its class in the show on more than one occasion. It is large, of perfect shape, sweet scented, and a continuous bloomer from early until late in the season. The colour is a soft rosy pink of a very pleasing shade. Whether as dwarfs or standards, in the open ground or in pots, this Rose is difficult to beat. It also has the desirable quality of coming good every season, and is one of our best Roses for town and suburban gardens.

SIR ROWLAND HILL.—This, staged by Messrs. R. Mack & Son in 1886, was a sport from Charles Lefebvre, and is a counterpart of that variety in growth and form. The colour is a deep velvety plum, most distinct, and really good when in its best form. But I fear it is not quite constant, occasionally reverting to Charles Lefebvre.

SOUVENIR DE S. A. PRINCE.—Introduced by Mr. G. Prince in 1889, this was a sport from Souvenir d'un Ami, and, like most sports, partakes of its parent in all but colour, which is a pale lemon white when young, becoming a pure white as it expands.

MRS. PAUL.—This is one of the most distinct Roses grown. It is a large flower with very thick petals, and when young has a decided Camellia form. The colour is blush white, with rosy peach shadings when growing in the sun. Very hardy, strong growing, and flowering freely when pegged down. It was shown by Messrs. G. Paul & Son in 1890.

SALAMANDER.—A H. Perpetual from Messrs. W. Paul & Son, Waltham Cross. This is an imbricated flower, of a bright scarlet and crimson shade. I have found it very free and good in the autumn, but it is not sufficiently double to retain its best form during a hot summer. It also is an 1890 variety.

MARGARET DICKSON.—This was the first gold medal Rose from the famous Irish firm at Newtownards, and was staged in 1890. Margaret Dickson has made growths of 10 to 12 feet with us, and when these have been pegged down few Roses could surpass it in free flowering. The first two seasons after introduction it was somewhat of a disappointment, few of us succeeding in opening it well. Whether it has become acclimatised to some extent or not, it is now a very reliable and beautiful Rose. It is of perfect form and shape, with grand foliage. Colour white with soft flesh-pink centre. I note that the N.R.S. catalogue calls it an ivory white, and does not mention its charming and delicate shade of flesh pink when young.

MARCHIONESS OF DUFFERIN.—In 1891 this was brought by the Irish firm. It is a Hybrid Perpetual of globular and slightly imbricated form. The colour is a soft rosy pink. It is a free bloomer, and a very vigorous grower.

MRS. W. J. GRANT.—In 1892 Messrs. A. Dicksons & Son exhibited this Rose, which resulted from crossing Lady Mary Fitzwilliam and La France. It is an exceptionally free bloomer, and a neat and compact grower. The flowers are made up of very large and deep petals, and are good from the bud stage until fully expanded. It is one of our best deep pinks for indoor culture, and I have found it a grand Rose for early forcing.

MARCHIONESS OF LONDONDERRY.—The year 1893 brought this dwarf and robust grower with its almost thornless wood. As a cut-back we have few Roses so floriferous. The flowers are very large and full, petals stout, and the colour almost pure white. This, as well as the next, came from the Newtownards firm.

MRS. R. G. SHARMAN-CRAWFORD.—One of the most reliable Roses we have. Its habit is much after Mrs. John Laing, but both shape and colour are distinct. The latter is a deep silvery pink with a clear flesh shade on the borders of its petals. The form is partially reflexed and imbricated, while it is a very free and continuous bloomer.

CRIMSON RAMBLER.—So much has been written about this Rose, which received the gold medal in 1893, that I need do no more than record the fact of its being the only non-exhibition Rose—as the term "exhibition" is understood by rosarians—to win a gold medal up to the present date.

MARCHIONESS OF DOWNSHIRE.—This was the winner in 1894. It is a soft satiny pink of good form and size, very free-flowering, and the blooms set well into handsome foliage of the Baroness Rothschild type. It has come good with me both upon cut-backs and maidens. A compact and robust grower, and one well suited for pots. This, with the three following, emanated from Newtownards.

HELEN KELLER.—The winner in 1895, is one of the most distinct H. Perpetuals. The colour is a bright rosy cerise, while the flower, if not so large as many, is well built up and the petals evenly arranged. It is a fairly good grower and very free blooming.

MURIEL GRAHAME.—The only remark needed in describing the Rose of 1896 is that it is a counterpart of its parent, Catherine Mermet, except in colour, which is a pale creamy white, very faintly flushed with rose while young. Nor can I dismiss this Rose without noting that during the first summer it was in commerce it secured two of the silver medals as being the best Tea Rose in the Crystal Palace and Norwich Rose Shows of the N.R.S. last year.

ULSTER.—This Hybrid Perpetual was the only winner in 1897. We can know little of this Rose, as it is not yet in commerce. But from the flowers shown, and the ground plant, I think it will be an acquisition, especially when we bear in mind that the raisers have never yet sent out a bad variety. It is a robust grower, smooth-wooded, and apparently free blooming. The flower is very large, and upon referring to my notes taken at the Crystal Palace, I find it described as "a very high coloured Caroline Testout, with its deepest shade prevailing throughout." That was my impression at the time.

It must not be forgotten that the dates when these Roses won the medal have no connection with the dates of their introduction to the public. In looking over the above list, it is very pleasing to note that all but one are of British or Irish origin, the exception being Crimson Rambler.—A. PIPER.

GEOGRAPHICAL DISTRIBUTION OF PLANTS IN RELATION TO WATERING.

(Concluded from page 287.)

THE West Indian Isles of Jamaica, Trinidad, Cuba, and Barbadoes have two rainy and two dry seasons each year, the average rainfall being 63 inches. *Ardisia crenulata*, *Pancratium fragrans*, *P. speciosa*, *Passiflora edulis*, *P. laurifolia*, *P. quadrangularis*, *Rondeletia speciosa*, *Xylophylla latifolia* are amongst the West Indian flowering plants. Orchids are represented by *Oncidium papilio*, *Phaius grandifolius*, *Vanilla aromatica*

and *V. planifolia*. Amongst Ferns there are *Phlebodium aureum* and many *Gymnogrammas*, the Palms also being abundant.

The rainfall of tropical Africa is considerably less than that of other parts of the tropical world, and even in its central equatorial belt 50 inches is rarely registered. Included in this category are Senegambia

Thunbergia alata (fig. 61), *Strelitzia regina*, and *Bertolonias*, with such Palms as the distinct and beautiful *Latania Commersoni*, *L. borbonica*, and *Areca rubra*. Also in the central equatorial belt, including Zanzibar, are found *Impatiens Sultani*, *Dracæna Goldieana*, and *Sanderiana*.

Passing to that portion of the New World within the tropics, Mexico

FIG. 61.—THUNBERGIA ALATA.

on the west coast, and Mozambique on the east, with the Islands of Madagascar, Socotra, Mauritius, and Bourbon. They have the year divided into rainy and dry seasons, the annual rainfall in Mauritius being 32 inches. The plants of tropical Africa comprise *Stephanotis floribunda*, *Clerodendron Balfourianum*, *Pentas carnea*, *P. Kermesiana*,

has a rainy and dry season, and the annual average fall is 90 to 100 inches. As its flora is distributed over the tableland, and not in the burning plains of the eastern and western coasts, the whole country is raised by a succession of mountains into the air from 4000 to 6000 feet, and although within the torrid zone possesses a temperate clime and moderate rainfall.

Amongst Mexican Orchids are *Cattleya citrina*, *Chysis bractescens*, *Lælia anceps*, *Lælia majalis*, *Lycaste aromatica*, and *Odontoglossum citrosum*. Succulent plants found growing on rocks include *Echeveria retusa*, *E. secunda*, and many Cactuses. Other native plants are *Aphelandra aurantiaca*, *Achimenes patens* and *picta*, *Bouvardias*, *Cobaea scandens*, *Cuphea platycentra*, *Habrothamnus elegans*, *H. fasciculatus*, *Lobelia fulgens*, *L. splendens*, *Lophospermum scandens*, *Dahlias*, *Fuchsias*, *Mina lobata*, *Poinsettia pulcherrima*, *Salvia patens*, *S. splendens*, *Sericographis Ghiesbreghtiana*, *Tigridia pavonia*, *Zinnia elegans*, and *Pentstemons*. One peculiarity of Mexican plants is their love of full exposure to sunlight. *Monstera deliciosa* is found where its roots can reach water in Mexican forests.

Brazil has no really rainy or dry season; the rainfall of its capital, Rio de Janeiro, is 75 inches, and at other stations 100 inches is registered. In the Departments of Ecuador, Guayil, and Rio Amazon, the annual fall is 276 inches. The air is continually humid from the vast forests in the plains of the Rio das Amazonas, where the mighty river Amazon flows; the winds blow alternately daily from land and sea, and it has a coast line of 4000 miles. Brazilian Orchids include *Cattleya labiata* varieties, *Chysis lævis*, *Lælia elegans* varieties, *Lælia purpurata* varieties, *Miltonia spectabilis* varieties, *Oncidium flexuosum*, *O. sarcodes*, and *Zygopetalum Mackayi* varieties. Amongst Palms are *Cocos flexuosa* and *C. plumosa*. On trees and rocks, as epiphytes, are found many Bromeliads, such as *Æchmeas* and *Vriesias*. Besides these there are such flowering plants as *Dipladenias*, *Begonia manicata*, *B. agrostigma*, *Epiphyllum truncatum*, *Franciscea*, *Gesnera zebrina*, *Hippeastrum aulicum*, and *Manettia bicolor*. *Adiantum cuneatum*, and *Philodendron Lindenii* are indigenous. On the Organ Mountains are found *Streptosolen Jamesoni*, *Pleroma elegans*, and *Lasiandra macrantha*, and at very high altitudes *Sophranitis grandiflora*.

Central America, including Guatemala, Venezuela, Costa Rica, and Colombia or New Grenada, have two rainy and two dry seasons annually, the average rainfall being from 40 to 60 inches. Indigenous Orchids are *Cattleya Trianae*, *C. Mendeli*, *C. chocoensis*, *Miltonia vexillaria*, *Odontoglossum crispum*, *Lælia albida*, *Lycaste Skinneri*, and *Sobralia macrantha*. *Utricularias* are found as aquatics, and *Anthurium Scherzerianum* in swamps. Other native plants are *Anthurium Andreanum*, *Centradenia floribunda*, *Thysacanthus rutilans*, *Amasonia punicea*, *Achimenes*, and *Cestrum aurantiacum*. Peru has a rainy and dry season, and its flora is distributed over the sierra or mountain slopes and valleys of the Cordillera of the Andes. *Bilbergias* are epiphytal here, and amongst native plants are *Daturas* or *Brugmansias*, *Heliotropes*, and *Urceolina pendula*.

Passing from the torrid to the temperate zone we find the rainfall is spread over the whole year. China proper has a very extensive range of climate. At Pekin in the north the average rain is 36 inches, while at Canton in the south 75 to 90 inches is the usual average. Chinese plants should at no period of the year become dry, and during the growing season unlimited supplies of water should be given. Amongst Chinese plants inhabiting our greenhouses are *Abelia rupestris*, *Akebia quinata*, *Camellia japonica*, *C. reticulata* fl.-pl., *Azalea indica*, *A. obtusa*, *A. ovata*, *Chamærops Fortunei*, *Bambusa Fortunei variegata*, *Daphne odorata*, *D. indica*, *Dianthus chinensis*, *Dielytra spectabilis*, *Farfugium grande*, *Hydrangea hortensis*, *Lobelia Erinus*, *Primula sienensis*, *Saxifraga sarmentosa*, *Rhynchospermum jasminoides*, *Spiræa palmata*, and *Chrysanthemum sinensis*, the original species of the race.

Madeira, in the Atlantic, at the extreme north-western point of the African continent, has an average of eighty rainy days spread throughout the year, and an annual rainfall of 30½ inches. The native plants are *Caladium bicolor*, *Clethra arborea*, *Jasminum odoratissimum*, *Solanum jasminoides*, and the red-berried *Solanum capsicastrum*. In the Canary Isles, close to the N.W. coast of Africa, the rainfall is small, and amongst native plants are *Phoenix canariensis*, the greenhouse *Statice*, the *Marguerites* or *Paris Daisies*, and *Senecio cruenta*, the original of the greenhouse *Cineraria*.

Cape Colony, in its elevated table land, has four months of summer, extremely hot and dry. The rainfall of remaining eight months is from 24 to 33 inches. On the slopes and plains are found *Freesias*, *Lachenalias*, *Ixias*, *Gladiolus Colvilli* species, *Nerine Fothergilli*, *N. sarniensis*, *N. corusca*. In the moister parts of the Table Mountain are found *Agapanthus umbellatus*, *Agathæa cœlestis*, *Aphelaxis*, *Burchellia capensis*, *Diosma ericoides*, greenhouse *Ericas*, *Pelargoniums*, *Plumbago capensis*, *Polygala Dalmaisiana*, *Tritonia aurea*, *Schizostylis coccinea*, *Vallota purpurea*, and *Calla æthiopica* (aquatic). On the sandy plains of the Karro are found *Mesembryanthemums*, *Aloes*, *Kalosantes coccinea*, and *Crassula jasminea*.

Chili in South America has a climate warmer than the South of England, and a rainfall of 60 to 90 inches spread throughout the year. Its flora is chiefly on the Andes—*Alonsoa incisifolia*, *Aloysia citriodora*, *Alströmerias*, *Calceolarias*, *Francoas*, *Schizanthus*, *Salpiglossis*, tuberous *Tropæolums*, *Mitraria coccinea*, *Desfontainia spinosa*, and *Lapagerias*.

The southern portion of Australia, whence all those plants styled New Holland plants were imported, has a season of three months of great heat and drought. The remaining nine months have a rainfall of very moderate degree. At Perth, in Western Australia, the average is from 23 to 30 inches, and at Adelaide, in New South Wales, the average is 20 inches. The native plants are *Dendrobium speciosum* and *D. s. Hilli*, *Dicksonia antarctica*, *Alsophilas*, and *Adiantum formosum*, *Acacia dealbata*, found in swamps; *Aotus gracillima*, *Blandfordias*, *Boronias*, *Chorozemas*, *Correas*, *Croweas*, *Epacris*, *Eriostemons*, *Grevilleas*, *Kennedys*, *Lachenalias*, *Phœnocomia prolifera*, *Pimeleas*,

Metrosideros, *Swainsonias*, *Tetratheca verticillata*, *Tecoma jasminoides*, *Seaforthia elegans*, and *Phoenix reclinata*.

New Zealand possesses a uniformly moist climate, without any seasons of drought. Its native plants are *Clianthus puniceus*, greenhouse *Veronicas*, *Coprosma Baueriana variegata*, *Nertera depressa*, *Dracæna australis*, *Clematis indivisa lobata*, *Dicksonia squarrosa*, *Cyathea dealbata*, *Areca sapida*, and *Caladium esculentum*.

To sum up, we find that in the temperate zone plants from China, Chili, and New Zealand require liberal supplies of water, and should never be allowed to get dry; whilst those from Australia, South Africa (Cape Colony), Palestine (whose rainfall on the mountain slopes is only 20 inches), Madeira, and the Canary Isles should be most carefully watered, and excess should be guarded against. In the tropical zone—West Indian, Brazilian and the Central American States, Cochin China, Borneo, Java, Sumatra, and Khaysia Mountains—plants should at no period of the year suffer from extreme drought; whilst Indian, Mexican, and Peruvian plants require a period of rest. Tropical African plants should be most carefully watered, and have a short rest in winter. In my last notes the rainfall of the Khaysia Mountains was given as between 500 and 600 feet instead of that number of inches.—F. STREET.

NOTES ON SALADS.

THE first thing I would like to impress upon the mind of the cultivator of salading is, that what may be termed the essential qualities of the produce can only be fully developed by the careful and timely observance of a few leading rules and principles of cultivation, and that mere cultural details are an elastic and variable quantity, which may be made to fit in with the circumstances of time and place; and secondly, that whatever is destined for the salad bowl should be grown well, and as quickly as is consistent with the nature of the plant and the season of the year, and this should be accomplished by what I will call "fair means." I would deprecate the use of sewage under any circumstances, and even ordinary liquid manure should be eschewed in the finishing stages of growth; in fact I would insist upon the cultivation being throughout of a cleanly and wholesome character, and this it may be if the land is kept in good heart, deeply and well worked, and the crop is allowed sufficient room for full development. These are what I will call "fair means," and by them we can surely and unfailingly raise salading of the necessary succulent quality. Everything, then, should be fresh, clean, crisp, juicy, and "nutty;" nothing of a woolly character is admissible.

It is well, too, to provide as much variety as means will afford, and though some portion of green is generally liked, we must never be short of well-blanced foliage. A Frenchman, whose salads used to be much admired and praised, once observed to me that in England a salad is often spoiled by too much vinegar and too much water. Well, I suppose the grower has seldom anything to do with the vinegar, but he may be responsible for some of the water if his salading happen to require much washing, a condition which I know full well is not easily avoided in a climate where clouds of dust and showers of rain come alternately. But that does not matter; what we have to bear in mind is, that the less washing is requisite the better. This remark, I need hardly say, applies to such things as grow above ground only, and not to underground parts. And now, having said so much upon leading rules and principles and essential qualities, I will refer to the cultural part of the subject.

It has been said, and with some truth, that the heart and soul of a salad is a Lettuce, for it would be difficult to find a perfect substitute for a good Lettuce, Cabbage or Cos. Each has its patrons and admirers, and in each class there are numerous varieties, some being suitable for sowing at one season of the year, and some for another. In early spring it is desirable to sow such sorts as turn in quickly, as at that time there is generally more or less of a scarcity of salading, and at the same time a large demand for it. The Early Paris Market is one of the best for the first sowing, and if put in early in February, brought on for a while in gentle heat, and finished in a cold frame, is most useful. Summer Lettuces require good rich soil, and I prefer sowing them where they are to stand when that can be done. Circumstances, however, will not always admit of this, and then we adopt the next best plan of sowing thinly in a bed from which they can be transplanted while yet small, care being taken to shade and water them according to the requirements of the time. When the young plants are well established and growing freely, a mulching of old Mushroom bed material, or something similar, laid on soon after a soaking of water, is beneficial in several ways, and will help to develop those fat-looking Lettuces that are admired and appreciated by nearly everybody. If liquid manure is used, it should be applied in a clear state, and only in the earlier stages of growth. There should be no suspicion of anything of the kind about the Lettuces when they come into use.

Blanching must not be forgotten when the time for it arrives, and it may be accomplished in a variety of ways. Tying up with a piece of matting answers very well, and is generally sufficient, but if a special pride is taken in this part of the work, a clean flower pot may be turned upside down over each Lettuce—a few at a time, according to the demand—care being taken not to leave them on too long, or the Lettuces will very soon either decay or "bolt." It takes about five or six days in the summer time, and later in the season a little longer, to blanch a green Lettuce of some of the Cos sorts, but such as have the habit of folding closely over often require little doing to.

Seed should be sown frequently during the spring and summer, and in July three or four sowings should be made, as from these will come

the autumn supply, while sowings for winter use may be made during August and the early part of September, perhaps a little later in some localities.

Endive is indispensable for autumn and winter use, and about three sorts are as many as need be grown. The Moss-curl is a good sort to sow about the middle of June for early use, to be followed by the Hardy Green-curl and the Round-leaved Batavian about the first week in July, and again about the end of that month. These three sowings will cover the period when Endive is most in request, but a small sowing a week or two earlier, and one rather later than the times named, may be made if circumstances demand it. Very early sown plants are, however, apt to run to seed prematurely, while very late ones do not develop fully before the cold weather puts a stop to growth. The cultural details for Lettuces will apply equally well to Endive with a little variation. Blanching is most easily effected by placing a piece of clean board over as many plants as are likely to be required in five or six days, pushing it on from time to time when a cutting is made, so as to keep up a constant succession of well blanched Endive. Tying and inverted flower pots may be resorted to where these methods of blanching are preferred. Some people lift a portion of the later sowing of this crop before hard weather sets in, and plant it out in a cold frame or house along with some of the later sown Lettuces, but I much prefer growing some of each in the frame where they are to remain, as these seem less liable to decay during winter than such as have been lifted when fully developed.—H. F.

(To be concluded.)

THE PLETHORA AND PROSPECTS OF GARDENERS.

I HAVE read and pondered over all that has been written lately on this subject, and though by nature of an optimistic turn, I have been constrained by certain present evidences to look in a pessimistic frame of mind as to the prospects of the present and future generations of gardeners.

I am driven to this by the enormous number of gardeners seeking employment. Just let us look at the advertisement columns of, say, the four principal gardening papers, and, to make a rough calculation only, we may make out 200 to 250 applicants for employment in the various departments of either trade or domestic gardening; and these it must be considered are only a portion—those who advertise, and the list does not include those who rely upon getting situations by private means, as nurserymen's, seedsmen's, or other personal recommendations.

Really, to me these columns are the saddest reading of the week, and they reveal a state of anxiety, of hope deferred, of vanishing means, of self-denials personally and domestically, if not of actual privations in some cases, of a sinking of spirits, and of a feeling of general, individual, and professional decadence. Men asking leave to toil, and not being allowed to do so. This is a very perplexing subject—a serious subject—indeed, none more so in the whole range of garden economy, and what are we to do?

The higher places of gardening are coming down—falling out as fast as they can, and gardeners of years and experience are having to submit to a reduction of their own salaries, a reduction of staff and their remuneration, and a turning of a once aristocratic garden into a market garden establishment, where everything is to be sold, from a bunch of Grapes to fronds of Maidenhair Fern, and from a Potato to a bunch of Radishes; the old gardener, who has guided and managed the place with plenty of help for years and years, possibly following his father, and who loves every inch of it, and every plant upon it, and is devoted to the family he has served so long, rather than make a change at his time of life, turns out to dig, and hoe, and weed. There's a pathos in this picture, which is no fancy one, beyond words. And then, amidst all this, one has to read of what may be termed a manufactory of lady gardeners, and swaggering that such and such a one has been appointed to such and such a place.

I am no fusty old bachelor; I have had the priceless blessing of a good mother, wife, and daughter, and my feelings for these and for women generally is chivalrous in the last degree, and I say, and say it emphatically, that only in a limited degree are women admissible in a garden. They are not equal to the general work. As a rule they have not had the requisite training for managing any place of importance. Their management would be either too exacting or too indulgent, swayed as they are by their feelings and emotions. In the lighter, artistic, delicate decorative work they might find a place; but then, our young men can do this now, and do it well.

Do these lady gardeners consider that by their competition they are taking the bread out of the mouth of some married sister, and out of the mouths of her children, by taking the place of that sister's breadwinner? Of course I shall be met by the taunt that girls cannot starve, they must live. I grant that freely, fully; but then, again, is there any sense of coming into a vocation for which they are manifestly unfitted, except in very conditional form? I say no, and I say it out loud, too, No! I expect I shall catch it. I do not mind, as I am only—AN OLD PROVINCIAL.

MR. STREET is not the only person who has written on this perplexing subject; indeed it periodically crops up for discussion, and after being well written about, all sorts of suggestions being made and then forgotten, the matter rests quietly until someone again revives it. The evil, if it be such,

however, goes on all the same, and young gardeners are being made by thousands yearly, for the simple reason that young men must find a livelihood somewhere and somehow.

Generally there seem to be more openings for young men in nurseries and market growing establishments than there are in private gardens, but that is only so ostensibly, as the number of young gardeners in private places must far exceed those in more public establishments. No doubt in the former the work is far more varied, wider in scope, and attractive in character. In market places especially the labour is arduous and monotonous, and devoid of that charm which always attaches to a beautiful and well-kept private garden. The labour in the latter may not, however, be the better paid. But in all cases young men, if they have ordinary powers of observation and intelligence as well as industry, find considerable scope for energy and instruction.

If we have not now as capable a race of young gardeners as the old rigid system of garden instruction, much of which was coarse, pedantic, and almost brutal, produced, then it is the fault of the youths themselves, because they have opportunities to acquire knowledge unknown to young men then. That many of our present youths will make first-rate gardeners there can be no doubt. A far more serious subject is their finding employment. That is the real question at issue. In relation to private gardening we are passing through something of a crisis. The great mainstay of this stronghold of horticulture hitherto, without doubt, has been found in the large private gardens maintained by our aristocracy and country gentlemen, for which Great Britain has been so famous. But many of these fine gardens are passing into other hands, or are being kept on as semi-market providers, with one half or less of the labour they once had furnished to them.

Has not this grave alteration in our old gardening associations something, if not much, to do with the present plethora of gardeners? Whatever may be the views held socially and otherwise to-day, no gardener can view this going under of so many of those who were once the stay and support of the best in horticulture with other than grave concern. We may have the fullest faith in the old adage, "There's as good fish in the sea as ever came out of it," and it is specially true so far as the race of gardeners is concerned; but can we feel assured that with rich people the old love and pride in gardening will continue to prevail?

Whenever death comes to some fine place it commonly means change in the cutting down of garden expenditure, and some declension of employment, with the discharge of young men. That helps to crowd the ranks of the unemployed. Young men, too, to-day seem less patient of occupying subordinate positions in gardens than used to be the case. When a young fellow has been foreman a few years, and has, perhaps, not exceeded twenty-six years of age, he pines to become a head gardener, ignoring the fact that a few years longer in a similar position in a different garden might do him immense service, and give him valuable experience.

The vocation is, relative to so many other occupations, a poorly remunerated one, but that is inevitable, because in private practice it administers so much to luxury. It is a beautiful and an attractive vocation all the same.—A. D.

[While we deplore most sincerely the inability of many worthy men and excellent gardeners to obtain situations which they could creditably fill, we are inclined to suspect that a greater amount of money is expended on gardens, and the raising of garden produce, now than during any past period. It is a change from the relatively few and "great" establishments to the immeasurably greater number of the comparatively small, but well kept, and much enjoyed gardens.]

As to the feared waning of interest in gardening by the wealthy and fairly well-to-do section of the community, we are not able to share those fears for two reasons. 1, Because there are probably ten times more honorary subscribers to local and provincial horticultural societies now than there were a quarter of a century ago. 2, Because of the constant additions to the roll of Fellows of the Royal Horticultural Society. Every meeting brings new supporters, and the total, we believe, now approaches 6000.

What we foresee is this: A number of young men who are trained in "great" gardens will have to be content with the charge of smaller; but fortunately, in many of these, happy lives may be spent, and intelligent gardeners highly respected. At the same time the increase of gardeners in the natural way will always be equal to the demand without any artificial manufacture for the sake of the fees for maintaining or increasing the value of the shares in scholastic institutions or otherwise.

We have no prejudice against lady gardeners as such, and if thoroughly trained, though they may not be "equal to the general work," they may be all the same capable directors. Not a few ladies have managed farms successfully, and are taking a large share in managing them now; and it is not easier to make farming lucrative than to make gardens productive, and in other respects satisfactory. The most competent gardeners, or "gardeners," will win in the end, and it will be the fault of the men if they are beaten in the race.]

KEW GARDENS.—These famous gardens, it is said, have been greatly beautified by the recent rains, and are now a delightful place for an afternoon's stroll, though of course not yet in full spring beauty. There is, however, no season of the year which has not its peculiar attractiveness at Kew, and just now in the open air it is the streets of Daffodils, and Scillas, Chionodoxas, and so forth, that are everywhere giving splashes of colour to the vivid turf. The natural mode of growing bulbs is infinitely more charming than the formal regularity of beds and borders.

THE "CARNOT" MYSTERY.

Re Mr. Haggart's query.—Madame Carnot is pure white, G. J. Warren is canary yellow (colour of Australian Gold), Mrs. W. Mease is pure primrose. They are three perfectly distinct varieties.—W. WELLS.

MR. WELLS, in a leaflet, publishes the following, which I ask you to place in parallel columns. The "puzzle" seems to me to decide how such sports happen. The dates suggest that the honour of having the first belongs to Mr. Lees, though granted that Mr. Knowles' is original, the identity of the leading features is remarkable. See below.

"Gardeners' Magazine," December 25th, 1897.

The plants of G. J. Warren distributed last spring were either too weak through over-propagation to give good flowers or else it is not going to prove so satisfactory as its parent, Madame Carnot. I have not seen nor heard of a really first-rate flower being shown, and one is inclined to the opinion that a guinea is too much to pay for a plant that is not vigorous enough to produce an exhibition flower.—W. H. LEES.

"Gardeners' Chronicle," February 12th, 1898.

Plants of G. J. Warren distributed last spring were probably too weak, or it will not prove so satisfactory as its parent. I have not heard of a really good first-rate flower being shown this season, and in my humble opinion a guinea is too much to pay for a plant that is not vigorous enough to produce an exhibition bloom.—E. KNOWLES.

This seems to be a case either of "too much alike varieties" or "the same variety under different names." It appears (if Mr. Wells is correct) that after seeing blooms Mr. Lees first ordered four plants of G. J. Warren and subsequently two more, and was so satisfied that he wished the name changed to Mrs. F. A. Bevan. He will be glad now, as his plants did not give a first-rate bloom last season, that the name was not changed.

It does not appear how much money Mr. Knowles expended over the variety, but he declares he had not heard (he omits the "seen") of a really "good first-class" bloom (Mr. Lees omits the "good"). If anyone has seen a first-class bloom that was not "good" would it not be a bit of a curiosity? We often hear of the same kind of Chrysanthemum "sports" occurring in different places, but it is not often that two literary "sports" so very much alike blossom within about six weeks of each other—one near Barnet, the other near Henley-on-Thames. Yes, this Carnot question is a "mystery." Who can solve the problem? I know nothing of Messrs. Wells, Lees, Knowles, or your southern dons, and am, as we say in our parts, "fair puzzled."—A NORTHERNER.

I HAVE read in your issue of 31st ult. (page 285), Mr. Alex. Haggart's justifiable remarks *re* the perplexing position in which the third Carnot, "Mrs. W. Mease," has been placed by such eminent experts as Messrs. Beckett and Wells through the Belfast dispute. As one who is much interested in the latest addition to the Carnot family I beg to ask your insertion of the following:—

Mrs. W. Mease is decidedly a very soft primrose in colour, and, as shown at Belfast, does not admit that sulphur yellow should be applied in the description, as the sulphur of commerce and canary yellow are too much alike.

I found Yellow Madame Carnot, as grown by myself, to be decidedly canary yellow, inclining to buttery yellow, and from what I saw of it as exhibited by other growers I have not seen any deviation. I also saw G. J. Warren exhibited at Belfast and Edinburgh. At Belfast it was exhibited by Mr. W. Wells, in juxtaposition to Mr. R. McKenna's first prize stand of twenty-four Japanese, which contained a fairly representative bloom of "Yellow Madame Carnot," as supplied by Mr. H. J. Jones, and although Mr. McKenna's bloom was the deeper yellow in colour, and the better finished and better built bloom of the two, taking into consideration they were grown under different cultural conditions, I do not consider them distinct.

I can assure Mr. Haggart, and the rank and file of Chrysanthemum growers, that they need not fear a recurrence of disqualification by using a bloom of Mrs. Mease in a stand with G. J. Warren when distinct varieties are required, as there is no similarity in colouring so close as Golden Queen of England and Emily Dale.

Mr. Mease stated verbally at the October show of the N.C.S. that his primrose sport had remained perfectly true, and was quite distinct from G. J. Warren—syn. Yellow Madame Carnot. I have it from an unimpeachable authority that the bloom exhibited by Mr. W. Mease in his premier stand of forty-eight at the N.C.S. Show last November, and to which was awarded the special prize as the best Japanese bloom in the show, was generally and popularly accepted as the third Carnot, so that if the officiating Judges dispensed their awards in darkness there must have been some considerable period of daylight while this show was in existence.

If my opinion is of any interest to the many readers of the Journal, I have much pleasure in stating that I unhesitatingly ordered, and have

been supplied with, Mrs. W. Mease, and I am pleased to say she is taking kindly to the change, and promises to do well.—HUGH CRAWFORD.

I AM not at all surprised to see on page 285 of the last issue of the Journal that your correspondent, Mr. Alex. Haggart is "mystified" *re* the yellow sport of Madame Carnot Chrysanthemum bearing the names G. J. Warren, Yellow Madame Carnot, and Mrs. Mease; but why there should be this confusion in the names I do not know, for it is a generally accepted fact that the two first names are given to the one variety, and therefore the term Yellow Madame Carnot should be dropped, as the first name was certificated by the Committee of the N.C.S. on November 1st, 1897, and previous to that an A.M. was given it by the R.H.S. on October 26th, 1897, on each occasion as G. J. Warren.

I would now ask, Is there any rule to prevent a plant which has been certificated by either or both of the above Societies under a certain name, and having been distributed to the public under that name, having it removed and another name substituted for it by persons in the trade?

If there is no protection against this, if the system of altering names is persevered in, buyers of new varieties will always be in danger of purchasing one variety under many aliases.

Mr. H. J. Jones, when sending out his Yellow Madame Carnot, stated in a note to the *Journal of Horticulture* (see page 4, January 7th, 1897) that if he found his Yellow Madame Carnot, was identical with G. J. Warren he would give it the latter name; but he does not do so, for I find in his catalogue of the present season he still adheres to "Yellow Madame Carnot."

Surely such an expert as this gentleman is in the Chrysanthemum world should use his best endeavours to prevent such confusion among the names.

With regard to Mrs. Mease being identical with G. J. Warren, I am unable to say from personal knowledge. I only know it was in Mr. Mease's grand exhibit at the Aquarium Show, and was there named G. J. Warren. Another season will remove many doubts on this point, but if this should prove to be identical with G. J. Warren it will be interesting to know under which name the painting which was awarded to it as the premier flower in the show will bear.

During the last season I grew eight plants of G. J. Warren. These were grown side by side, and the buds were selected on each plant so as to have flowers of this variety for as long a period as possible. The last bloom was cut as late as the first week in March. On these eight plants there were scarcely two flowers of the same shade of yellow, as the colour varied on the different plants from a deep canary to a pale primrose. What, I would ask, was the cause of this? Were the deeper colours caused by the plants being more vigorous, or *vice versa*? I should be glad of the opinion on this point of greater experts than—G. J. WARREN, Balcombe Place.

[If, and when, it is admitted by competent authorities who have no interest in the retention of a particular name, that two plants bearing different names are identical, then according to the universal rule established by long usage, the name first recognised, and under which the plant was certificated, is the only right and correct one, any others that may be attached to the same plant being usurpers. Any systematic infringement of that intelligible and perfectly reasonable rule would be calculated to lead to serious confusion and disappointment among purchasers of plants. At present the question of the distinctness or otherwise of the Chrysanthemums G. J. Warren and Yellow Madame Carnot seems to be very much a matter of trade opinion. If the point is not settled before the autumn shows, there will evidently be grave risks of disqualifications occurring. Has it been clearly stated when, where, and with whom the yellow variety exhibited by Mr. Jones, under the name of Mrs. F. A. Bevan, at the December show of the N.C.S., originated, and by whom the blooms were grown? It is not unusual for "sports" very similar in appearance to occur in different localities during the same season. The appearance of these two yellows seems to be a case in point. The origin and history of one is clear—G. J. Warren; and it is difficult to imagine why similar information should not be forthcoming in respect to the other. Raisers of new plants are generally ready to supply full information respecting them, but occasionally the matter is inadvertently overlooked.]

SEASONABLE NOTES ON CHRYSANTHEMUMS.

ALL who are anxious to have high-class Chrysanthemum blooms in November, either for exhibition or home use, must now be fully prepared to give them close attention. The fine blooms we see during the autumn are not produced in two or three months, but are the result of much care from now onwards. In the first place I consider it of the utmost importance that the cultivator, be he large or small, should estimate the number of plants he can pay attention to and comfortably house when the time comes. I venture to say more collections are spoilt through attempting too many than from any other cause. Overcrowding at all stages is a serious mistake.

Having decided on the number of plants to grow, another important step is the selection of varieties. If required for exhibition no one can do better than carefully study the past pages of the Journal, as I consider the returns sent to Mr. Molyneux by most of the leading growers and published therein, are of great assistance not only to beginners, but to all interested in the cultivation of Chrysanthemums. Personally I should much prefer if each contributor's list could be published as sent in, one would then have the benefit of the most successful exhibitor's choice. Another grave mistake made by many growers is attempting too many

varieties, especially so in small collections. It is far better to grow more of the leading varieties, and I would caution beginners against going in for numbers of novelties, especially as there are so many well tried first-rate sorts now to select from. Only too often the new kinds which are of great promise are forced and propagated so hard, that good blooms can hardly be expected the first year, and often flowers that have received notice as promising are never heard of again, though I contend if good flowers can once be produced there is no reason why they should not be produced again.

By the time these lines are in print, assuming the young plants have been properly cared for, they should be ready for potting from 60-sized pots to 32's. I am aware that many growers believe that much success depends on the mixture the plants are grown in, but I can assure them there is really not much in this. Good drainage and a sweet porous mixture, however, are essential. For this potting I advise two parts good fibrous loam, one part spent Mushroom bed refuse, and one part well-decayed leaf soil. The loam should be pulled well to pieces with the hand, leaving in all the fibre. I prefer loam that has been cut and stacked about six months from a good rich pasture. The leaf soil and manure should be passed through a half-inch sieve, and to this must be added enough good road sand to keep it open, thus allowing the water to pass away quickly. To every barrowload of the above add a 10-inch potful of bonemeal, the whole to be thoroughly mixed.

The pots and crocks should be thoroughly washed and quite dry before using. Perfect drainage at each potting I consider of the utmost importance, yet how often one sees this performed in a slovenly manner. In my early days of gardening I had this thoroughly drilled into me, and repeatedly since have I seen the value of the advice then given. The drainage ought to be as perfect when the plant is turned out at any time as when first placed in the pot. How can anyone expect plants to keep in a healthy condition unless the water can pass freely through the pots? One large crock should be first placed over the hole in the hollow position, carefully building up the amount required in layers, gradually making each layer finer, the final one being quite fine, but not dusty. On this should be placed sufficient good clean fibre, taken from the loam heap, to prevent the finer particles of the soil being washed into the drainage when watering. Of course worms must be excluded from the pots at all times, or they will quickly upset the drainage arrangements.

All being ready, the potting can be proceeded with, and when turning out the plants I never attempt to remove the fibre which covers the drainage, or even the smallest crocks, as this will prove more beneficial than otherwise, and many of the principal roots will not be damaged. The soil should be made quite firm, and a small neat stake ought to be placed to each plant. Cold frames ought to be in readiness to receive the plants. We always practise standing the pots on strips of wood in preference to ashes, thus making sure against the intrusion of worms. The plants may be well damped, but not soaked through; we generally do this about four days after potting. The plants must be kept close, syringed twice a day, and, if the weather should be clear and sunny, a thin shading should be afforded them, thus giving as little a check as possible. After the plants have recovered from the slight shock of removal, and if the weather be favourable, admit air much more freely; indeed, from four o'clock till bedtime the lights should be removed altogether, and when I say removed I mean lift them off entirely; merely pulling them back is not sufficient for me, as I am a great believer in fresh air. A north or north-east wind with sun is the most trying, of course, to all newly potted plants.

The points of the plants should be dusted every ten days with tobacco powder, which will keep them free from aphids. The new leaf rust, unfortunately, promises to be a source of great trouble. Many of my friends have had some experience of it already, but so far we have been fortunate in escaping. My advice is, Keep a watchful eye and endeavour to stamp it out on the first appearance by picking off the affected leaves, keeping them well dusted with anti-blight powder, and remove the plants that are at all suspicious away from the general stock.

Stopping is now practised much more than formerly, thus enabling the exhibitor to select the bud which is likely to prove the best bloom at some given date. The locality in which one resides, the varieties, and dates of shows, will have to be considered, but, generally speaking, the end of March and the month of April will be found the best time. As, however, the seasons are so uncertain, I advise only stopping some of each variety, as oftentimes the natural break will produce the best blooms, with the exception of the Queen family, part of which should be stopped at the end of March, and the remainder about the 7th of April. Pompons and Pompon Anemones grown in bush form for producing exhibition blooms, should all be stopped at this season once only. These make handsome plants for any purpose, and it is surprising to me that they are not more cultivated, as a good collection, well grown and arranged, is in my opinion quite as interesting and useful, if not more so, than the larger types; but this section I consider is being spoilt by mere size. Many of the hybrid varieties are now included at many shows. That charming variety Elsie Dordan to my mind represents the true type of a Pompon. The disbudding of these is often carried too far, which robs the plants of much of their natural beauty. I believe in a judicious thinning of the buds—just sufficient to allow the blooms to expand properly. Plants of any section intended for specimens should receive every encouragement, and must be kept in a genial temperature, quite near the glass, where abundance of air can be given them on all favourable occasions. They should be stopped frequently, and kept tied down.—EDWIN BECKETT, *Aldenham House Gardens, Elstree, Herts.*

CYRTANTHUS MACKENI.

SEVERAL very beautiful and brilliantly coloured species of *Cyrtanthus* are known; but though the one shown does not excel in brightness of colouring it is one of the most graceful and free-flowering of the genus. The flowers (fig. 62) are creamy white, or occasionally with a distinct yellow tint, and they are produced on strong scapes 6 to 9 inches in height. It is very easy of cultivation, succeeding well in an ordinary

FIG. 62.—CYRTANTHUS MACKENI.

greenhouse, but it requires a moderately rich light soil, and plenty of water when growing. I have had it for several seasons extremely fine in 3 and 5-inch pots, and strongly recommend it for more extended cultivation.—L.

EMIGRANTS' INFORMATION.—The April circulars of the Emigrants' Information Office and the new annual editions of the penny handbooks show the present prospects of emigration. This is the best season of the year to emigrate to Canada; there is a good opening for experienced farm hands. Good practical miners are always in demand at the large Broken Hill silver mines in New South Wales, and high-class men of all trades have no difficulty in finding employment there; but there is no opening for unskilled labourers. In Victoria and South Australia there is an ample supply of all kinds of labour at the present time. In Queensland the demand for labour is small, but the numerous railway and other works, which are now in progress, are helping to provide labourers with work. In agricultural districts there is a demand for good ploughmen and farm hands. The sugar industry is in a prosperous condition, and there are excellent openings for farmers with a little capital, after they have acquired some experience of the country. In Tasmania there is no demand for more mechanics or farm labourers. In New Zealand there has been plenty of work in nearly all parts for mechanics and country labourers. Cape Colony is well supplied with ordinary labour.

MARIGOLDS.

CALENDULA officinalis, the common Marigold, possesses a long and honourable record. It was not until the sixteenth century that "*Calendula*" was applied to it, and this name was given because of the procession of its flowers through each month of the kalends. Previously it was known as *Caltha vulgaris*—the common "cup" shaped flower. With it, some other plants bore the name of *Caltha*, and it is curious that every one of these, though it is in some instances impossible to discover any affinity to the true Marigold, bear that name also. Thus the African Marigold was *Caltha africana* major, *C. a. minor* bring the French Marigold. *C. sylvestris* was the Corn Marigold; and the Marsh Marigold, the only plant that now bears the designation, is *Caltha palustris*, in olden times saluted as the "King Cup," though Gerard declares it ought to be "King's Cob."

"Gold" was applied to several plants, and underwent many variations, as for example—Guldes, Gools, Goulions, Gowans; which last, though now appropriated by the Daisy, means, in fact, a golden flower. "Marigold" is, of course, "Mary's Gold," and was a flower on many accounts highly valued; but its position of honour arose, no doubt, because of its relation to the Virgin Mary. How it fell into disrepute we cannot now tell; but the probability is that the dressing of shrines, which ceased at the Reformation, and the consequent disuse of garlands to "dight" images of the Virgin, would have an immediate effect in lessening its cultivation. It continued in use as a garland and a nosegay flower till at least the time of Shakespeare, and nothing finer in the language exists than the great poet's references to this humble flower. He selects it as the flower to compare with the eyes of the sleeping Lucrece, which,

"Like Marigolds had sheathed their light,
And, canopied in darkness, sweetly lay
Till they might open to adorn the day."

Double Marigolds were cultivated for the beauty of their flowers as early as the sixteenth century, perhaps much earlier, and they are mentioned early in the eighteenth century as preferable to the single for kitchen and pot herbs. A little later Phillip Miller names the following as then in cultivation. "The common single, the double flowering, the largest double flowering, the double lemon-coloured flower, the greater and smaller childing." The two last produced small flowers round the edges of the capitulum in exactly the same manner as the Hen-and-chicken Daisy. In 1789 "*The Gardeners' Vade Mecum*" has a still longer list.

At the present day the varieties most worthy cultivation are Meteor, generally well known; Prince of Orange, and Le Proust. The best, however, include the large-flowered Orange, distributed some years ago by a continental firm, and which, when in flower, produces a most effective border or bed. Also worthy of attention is a large-flowered lemon-coloured form which appeared three or four years ago. In Messrs. Dobbie & Co.'s nurseries I have seen growing a variety exactly like the first of these, but possessed of a very dwarf habit.

The old growers sowed in February, but April or even May is soon enough to sow for autumn effect, and July for winter and spring flowering. Where a large amount of space is to be covered it is decidedly better to raise the plants thinly in a bed, and thence transplant them to their flowering positions. They may be set as wide as 15 to 18 inches apart, and towards autumn the plants require trimming to keep them in bounds, and in a floriferous condition. Varieties rapidly deteriorate, and as a rule it is better to purchase annually from a reliable source than to depend on home-saved seeds.—R. P. BROTHERSTON.

NATIONAL AMATEUR GARDENERS' ASSOCIATION (LIVERPOOL BRANCH).

MUCH work of a practical nature has been from time to time performed by the above branch, but only a few weeks back some feared that it would collapse altogether. Anyone, however, taking a casual glance at the large Hall, Hackins Hey, Liverpool, on Thursday evening last, would have thought otherwise. The room had been gracefully draped by Messrs. Frisby, Dyke & Co., Liverpool, the platform end being beautifully adorned with *Amaryllis*, generously sent by Messrs. R. P. Ker & Sons, Liverpool. At the other end Mr. R. Pinnington of Roby had arranged many vases of choice Orchids, Camellias, and numerous spring flowers, the whole presenting quite a transformation to one accustomed to seeing the room on ordinary meeting nights.

All this had been brought about by a select Committee suggesting a conversazione, and in the hands of Mr. J. M. Smyth as principal (a gentleman who takes a great interest in the welfare of the branch), success was at once assured, an excellent attendance of ladies and gentlemen being present, who thoroughly appreciated the high class programme of music provided by Messrs. Smyth and Pinnington.

The President, J. H. Drake, Esq., was happy in his remarks, trusting that the ladies would join their ranks and so encourage the Committee to make their syllabus more attractive. It is pleasant to record that Mr. Drake's remarks had the desired effect of making many new members. Mr. Histed proposed, and Mr. Butcher seconded, the vote of thanks to Messrs. Frisby, Dyke & Co., R. P. Ker & Sons, R. Pinnington, and the artistes who had so kindly provided so admirable an evening's enjoyment, each expressing the hope that it would only be the forerunner of many more.

To all, but more especially to Mr. Smyth, the highest praise must be accorded for the arrangements.

LIVERPOOL SPRING SHOW.

MARCH 30TH.

ON Wednesday last the thirteenth spring show was held in the St. George's Hall. As compared with former years the exhibits, although showing a slight falling off in number, were fully up to the excellent quality, and visitors had a really pleasing display for their delectation. A feature reflecting the greatest credit on the stagers was the lowering of the central row of tables, and these were placed at the disposal of the trade, with the result that the effect produced was of the most gratifying character, enabling as it did every plant to be seen to advantage. Two other tables ran the whole length of the hall, these being filled with forced bulbs.

The trade exhibits were of a very high order. Messrs. Dicksons, Ltd., Chester, staged a lovely and interesting collection of *Narcissi* and other bulbous flowers, the arrangement being very striking. Messrs. R. P. Ker & Sons, Aigburth Nursery, Liverpool, were again in splendid form with a grand collection of *Amaryllis*, free flowering, brilliant in colour, stout in texture, and of superb form. Noticeable, too, were the *Azaleas mollis* and *indica* in variety, and decorative plants that completed the fine stand. Messrs. Jno. Cowan & Co., Ltd., Gateacre and Liverpool, had many choice varieties of Orchids, *Azaleas* and Ferns being used with advantageous effect. Messrs. T. Davies & Co., Wavertree Nursery, Liverpool, had a display of *Polyanthus Narcissus*, Lily of the Valley, and bulbs in variety. Messrs. Turner Bros., Liverpool, exhibited floral designs of the highest quality. Mr. B. Ashton, gardener to the Right Hon. the Earl of Latham, staged a box of Royal Sovereign Strawberry, and was with the above named firms awarded the Society's certificate of merit.

Three entered for the group of miscellaneous foliage and flowering plants, 12 feet by 10 feet, arranged for effect in square form. Mr. E. Taylor, gardener to E. Pryor, Esq., Royston, Aigburth, won with a tasteful arrangement in which some well-cultivated Orchids predominated; the second place was taken by Mr. J. Bracegirdle, gardener to W. H. Watts, Esq., with an altogether lighter arrangement, the quality of the plants not being quite so prominent; Mr. F. Field, gardener to J. H. Wilson, Esq., was third, with bright plants.

Ten pots hardy herbaceous and bulbous plants brought five competitors, all having plants of excellent quality, Mr. Ankers, gardener to W. B. Bowering, Esq., Grassendale, winning with fine Solomon's Seal, *Spiræas*, *Dielytra*, *Iris*, *Daffodils*, and *Doronicum*; Mr. T. Hitchman, gardener to Arthur Earle, Esq., Childwall Lodge, being a good second, the latter winning with twelve pots *Polyanthus Narcissus*. For a display of miscellaneous bulbs and foliage plants Mr. Bracegirdle was an easy first with a bright show. Mr. T. Wilson, gardener to O. H. Williams, Esq., was second. Hyacinths were not up to the usual Liverpool standard. For twelve Mr. T. Wilson, a noted winner in this class for many years, was again to the fore. Mr. G. Leadbetter was an excellent second. Mr. Finch, gardener to Joseph Smith, Esq., Newstead, Wavertree, was a capital first for six. For six pots Hyacinths, 7-inch pots, three bulbs in a pot, Mr. Leadbetter was deservedly placed first with dwarf well-flowered specimens, perhaps amongst the finest ever seen at Liverpool. Mr. J. McColl, gardener to J. W. Hughes, Esq., New Heys, Allerton, was a fine second.

Tulips were not very extensive, but of splendid quality, Mr. H. Holford, gardener to C. MacIver, Esq., Beechfield, Heswell, winning for twelve. Mr. J. Williams, gardener to C. J. Procter, Esq., Boscobel, Nocturnum, had a beautiful dwarf set for second position. For six pots Mr. Hitchman showed well. Mr. J. Williams had a pretty six doubles. For three greenhouse *Azaleas*, not exceeding 8-inch pots, Mr. W. Bustard, gardener to T. McClelland, Esq., Aigburth, had charming plants. Five entered for six *Amaryllis*, the prize being taken by a noted grower, Mr. T. Johnson, gardener to G. W. Moss, Esq., Aigburth, with grand examples, Mr. Leadbetter following with noteworthy examples.

The baskets of flowers, the prizes for which were presented by Messrs. Dickson & Sadler, the Secretaries of the Association, were again a very beautiful feature, Mr. G. Eaton, gardener to W. H. Shirley, Esq., Allerton House, Allerton, being placed first with a charming arrangement of Orchids, interspersed with *Asparagus plumosus*. Mr. Carling, gardener to Mrs. Cope, Woolton, was a remarkably close second, the judges having much difficulty in awarding the prize.

For a greenhouse plant in flower Mr. E. Taylor had a handsome *Acacia dealbata*. For a stove plant in bloom Mr. Randall had a superb *Cœlogyne cristata*. Mr. Bracegirdle for three Orchids had *Dendrobium Wardianum*, *Cymbidium Lowianum*, and a magnificent *Angræcum sesquipedale*; Mr. E. Taylor second with fine *Cymbidium Lowianum* and *Dendrobium nobile nobilius*. Mr. Taylor won with a single Orchid, having *Cœlogyne cristata* abundantly flowered. Mr. Taylor was easily first with two Orchids, having grand *Odontoglossum maculatum* and the seldom seen *Odontoglossum coronarium* in superb condition.

Mr. Bracegirdle scored heavily with three Callas. Mr. Geo. Eaton won with two forced hardy plants, and also with a splendid specimen *Davallia Mooreana*; Mr. Bracegirdle showing superior quality in the class for four exotic Ferns. The classes for four and one *Azalea* contained nothing to call for special comment, Mr. A. H. Randall, gardener to A. L. Jones, Esq., Aigburth, and Mr. E. Taylor, winning, the latter winning with one hardy *Rhododendron*, and Mr. Bustard with a good four. The latter also succeeded with six forced hardy plants. A superb *Rhododendron Gibsoni* won a prize for Mr. Randall. Messrs. Bracegirdle and Carling had well-conditioned Palms. *Cinerarias* and *Primulas* were fair, the winners being Mr. T. Ankers, and E. Edmondson,

Esq. For six clumps of Lily of the Valley Mr. Carling was invincible in a strong competition. Mr. Finch won with Mignonette and table plants. Mr. Harrison, gardener to Mrs. W. G. Bateson, Allerton, had four floriferous Azalea mollis, and H. H. Hammond, Esq., one. Bouquets were well done, Mr. J. Williams winning. Mr. Field won the last of the list with six Freesias. The Chairman, Mr. Foster; Vice-Chairman, Mr. Mercer; Secretaries, Messrs. Dickson and Sadler, and the Committee (staging) were prompt and courteous in their duties, whilst the music supplied by Mr. C. A. Black's orchestra was of the highest class.

THE YOUNG GARDENERS' DOMAIN.

AN APPEAL.

THANK you, "Old Boy," for your vigilance over us youngsters, and for your reminder of our apathy. I have read your article on page 226 several times, and the more I think it over the more is its depth of meaning impressed on me. Wake up young gardeners of Britain, let us not be threatened with the "veto" on our "Domain." Do we know, can we foresee, what being contributors to the Journal may mean for us in the long run? I think not, or we should be more energetic in our endeavours, not only at self-improvement, but by taking the opportunity here offered us.

Speaking of self-improvement, I often envy the lot of the young gardener who may be near a town, or where he may have the chance of attending a series of lectures on horticulture. I think they have an advantage over those who are far away in the country, as myself, where there is no opportunity offered for such, and the wish is never gratified. In this case we should study our garden papers and literature pertaining to horticulture more assiduously, so that we may compete with our more favoured compeers; study the writings of other men, and take the leaf from their book. I often notice shorthand mentioned as being necessary for a young gardener, but for myself I cannot yet see its utility. There are other subjects we could study with greater advantage to ourselves. Alas! how many young gardeners of to-day are barely acquainted with the primary subjects of elementary education? Through perhaps no fault of theirs, they were not fortunate enough to receive much schooling. But there is a course open. Take the opportunity of attending a continuation school, and in what place, however remote, is there not one of these carried on? You who are unluckily so placed take the chance, never mind what the world says; fear not in showing your shortcomings, you will overcome them by persevering study, and may come out victors at the last. There is nothing to lose, and much to gain. Our faults are leniently dealt with. Our Editor must be very patient with us, or he would not forbear as he does. We need fear no harsh criticism, and as for fearing jokes from our bothy associates, that can easily be avoided by a *nom de plume*.

Let us hope the next time "Old Boy" occupies our "Domain" it may be with praises to us. We should be ashamed of ourselves to have come to this. As for those half dozen bright pens, whoever they may be, let them strive on, work on, make it their object, as I intend making it mine, to be invited to leave "The Domain" and enter the arena, where they may cope with any friendly antagonist, and not come off second best. Then, as "Old Boy" sees our names taken from the page, may he indeed know that his seeds have fallen on good ground, grown, borne fruit, and will continue so to the end.—SEMPER.

A SCRIBBLE ON SCIENCE AND PRACTICE.

MY conscience has been stirred by the comments of "A Young Scot" and others, so I venture a scribble. The gardener with the above synonym brought to my mind by his energetic epistle (page 247), a subject which I have often thought about. We may have noticed that there are different kinds of gardeners—I mean as regards their energy and aims.

I was, at one time, deeply impressed by the scarcity of the thoughtful and (may I venture it) scientific class of gardeners, and although I am still sensible of the scarcity of that class, I am more aware of its growth. Indeed, in some circles, I find that the scientific side of gardening is sometimes pursued to an unsafe extremity.

It is surely better for a gardener to know the proper rotation of crops and to be expert with the spade and hoe, than to know that the Turnip belongs to the natural order Cruciferae as well as the Candytuft, or that the Carrot is in Umbelliferae with the Parsley. The latter information is undoubtedly good if it accompanies the former, but if it is to be a choice between the two let us have the practice *minus* the science rather than the science *minus* the practice.

But a harmonious blending of the two is quite attainable—indeed, it is almost essential for a good up-to-date gardener. The perfect harmony of practice and science seems to me the acme of gardening, and it is a state of things perhaps too seldom met with. To finish with a demonstration I will try to describe an incident I noticed a few weeks ago.

Two gardeners, A and B, were about to water some plants in a sub-tropical house. They had to take water from a tank which had hot pipes along the top on one side to warm the water. A drew B's attention to the vapour rising from the water at the hole where they had to dip in their cans. When A put his hand in the water at that part, he proclaimed that it was too hot for watering plants with, and was at a loss for a remedy. They could not run in any cold water, because the tank was replenished by the rain.

At last B, thanks to his knowledge of physics, suggested that the

warm water was only at the surface near the pipes, and that the water at the bottom was cold. He proved it by vigorously stirring the water with his can, when it was found that the water had been made quite cool. This is one of many instances I have seen, and it serves simply to show that the practical application of elementary science is a thing to be aimed at by gardeners who would rise in their calling and take as their motto—EXCELSIOR.

[This is Excelsior No. 2. He is a good penman, and may "scribble" again.]

WINTER SALADS.

I PROPOSE giving short cultural notes on the different vegetables used for the above purpose, and which have been under my notice during the past season. For Mustard and Cress we fill shallow boxes with fine soil, and sow the seeds on the surface. The boxes are placed in heat, watered with a fine-rose can and shaded with a board or thick paper. Sow the Cress three days previous to the Mustard, as the former takes longer to germinate, and they can then be used together. When an inch high remove to a cool house.

Several varieties of Endive are grown, and I have found the Green Batavian the most highly appreciated. It is exceptionally hardy, and survives severe weather better than any other I have seen. Sow seeds early in August, in good rich soil, on a south border, transplant in rows a foot apart each way. Water must be given when necessary, and hoeing is beneficial to the plants. These are lifted before severe weather sets in, and planted the same distance apart along the front of an unheated Peach case. Abundance of air is given on all favourable occasions. In November enough are lifted to fill a seed box when packed closely together. The soil used about the roots must be very moist to avoid watering after planting, as they are apt to damp. Place the box in the Mushroom house, and in a few days the plants will be bleached ready for use. This can be done as often as is necessary to maintain the supply, but the number of plants prepared must be regulated by the demand.

Chicory deserves to be better known, the young growths being very useful as a salad. It should be treated precisely the same as main-crop Carrots. When lifted in autumn the roots must be stored in sand. A number can be placed in the Mushroom house in the same manner as Seakale, and used when 2 or 3 inches long.

Of Lettuce sow seeds in August, and again in mid-September, on a warm rich border, and as soon as large enough prick out into cold frames, the nearer the glass the better. Protect them from frost and give them plenty of air when not raining or freezing. Beware of slugs, and pick off all decayed leaves. All the Year Round is a suitable variety and quite hardy.

Seeds of Celery may be sown in boxes of rich soil in a warm house about the middle of March and again a month later. Place 3 inches of stable manure in a cold frame, tread it firmly, and surface it with 3 inches of rich soil. As soon as the seedlings are large enough prick them out 3 inches apart. Keep the plants close and shaded for a few days, and when growing freely afford abundance of air and moisture at the roots. Never allow the plants to receive a check, and when they are 6 inches high plant in well manured trenches. Subsequent treatment will consist of copious waterings with liquid manure, also taking off side shoots and earthing up for bleaching.—NIL DESPERANDUM.

BANANAS AT HOME AND IN JAMAICA.

IN answer to the appeal of "Nil Desperandum" (page 268), for information on this excellent fruit, I will describe how plants of Musa Cavendishi were treated during 1897 and 1898. They were growing in 12-inch pots in a large stove, and in February were placed in large, well-drained tubs, using a very lumpy and fairly rich loam. The tubs were made by cutting asunder an empty paraffin cask, painting the woodwork green and the hoops black, affixing thereon two strong iron handles, and a better tub for our present purpose cannot be wished for.

The temperature of the house averaged 60° at night, and was allowed to rise to 80°, or even 85°, by day, little air being given. The plants grew very fast, and were assisted with copious supplies of liquid manure. On the 16th of September I observed the fruit spike in the centre of one of the plants, while the other was a fortnight later in making its appearance. Liquid manure was given until the fruits had about three parts grown, and then discontinued, on the advice of a friend (about whom a little will be said later on), his theory being that sufficient nourishment was now contained in the fleshy trunk to supply the needs of the fruits then hanging.

About this time the stalk extension beyond the fruit was removed. The temperature of the stove being likely to fall too low, the plants were removed to an early vinery in January of this year, in a temperature of 55° at night. Here they have remained until the present time, the heat of the vinery being regulated to suit the Vines. The Banana fruits may be observed to change colour almost daily. For the last eight or ten weeks the plants have received little water; it has not been withheld altogether, on the contrary enough has been supplied to keep the roots in a healthy condition.

The fruits will probably be allowed to ripen on the plants. They may, however, be cut at any time now, and hung in a light dry place, when they will be fit for table in ten days or a fortnight. The flavour of these artificially ripened fruits will not be so good as of those ripened naturally, provided a dryish atmosphere be maintained in the house. The time of fruiting depends upon the time the suckers are potted, and in what temperature the plants are afterwards grown. Obviously it takes from

twenty to twenty-four months from the time the sucker pushes through the soil until the fruits are perfected in this country.

And now about my friend. In March, 1897, he arrived in this country from Jamaica, where for some time he had charge of considerable Banana plantations, and the following account of his experience, which he has kindly given to me, I endeavour to convey in my own words.

The suckers are planted 16 to 20 feet apart each way in the month of March, or just before the rainy season commences, and are prepared in the following manner:—The head of each sucker is removed in a slanting direction, making a clean cut, the remaining part of the sucker being 1 foot out of the ground when planted. This is done in order to insure plenty of roots before upward growth commences, otherwise the trunk would be weak and spindly, and the bunches proportionately small. This preparation of the suckers is considered an important thing in Banana cultivation, and is recommended to be practised at all times.

Suckers generally produce fruit fourteen months from the time of planting in their native habitat (that is, in the tropics). The average temperature in Jamaica is 80° Fahr., it seldom goes below 60° at night, while it often attains 120° by day in the shade. The Banana produces two crops each year, and the season of fruiting is determined partially by the cultivator in the judicious removal of suckers; one or two are left to take the place of the parent when fruiting. The first, and best, crop is mostly fit for export in February, and the second crop the following August.

The watering is done by irrigation, and the Chinese are the best irrigators. A plantation will last from three to twenty years, according to the nature and depth of soil, and by careful removal of suckers the rows are maintained fairly discernible. The bunches are supported during the growing season by two stout bamboo stakes placed crosswise under the stalk of the bunch. The fruit extension stalk is not cut off beyond the actual fruit, but is allowed to grow until the fruit is gathered, the old trunk being removed at the same time to give place to the young suckers now well advanced in growth.

The work of gathering begins as soon as the fruits are fully grown, and while they are quite green. Coolie women do most of the gathering and carrying. A strong girl will carry a 1-cwt. bunch of Bananas after it has been placed on her head a distance of 200 or 300 yards from the plantation to the packing shed with ease. The bunches are wrapped carefully in a good quantity of dried Banana leaves, and as soon as a sufficient number has been prepared they are taken immediately to the ship, and arrive in this country in a semi-ripe condition as we see them hanging in our English shop-windows.

The individual fruits are called "fingers," the clusters of fruit "hands." Usually fourteen fingers go to a hand, while it takes nine hands to make a "bunch." A cluster consisting of less than nine hands is not considered good enough for export. A "bunch" of Bananas in Jamaica costs from 1s. 3d. to 1s. 9d. The fruit is eaten by the natives cooked in a green state, and forms one of their chief articles of food.—T. P.

[We congratulate our correspondent on his clear and intelligent description of the culture and exportation of this nutritious tropical fruit.]

RAISING BEDDING FUCHSIAS.

THE culture of Fuchsias is by no means a difficult process. The old plants, lifted in the autumn and potted if started near the glass in the early spring, in a short time produce a splendid lot of young growths. Take these off when they are about 3 inches long, and insert them in either pots or pans, using a mixture of light sandy soil. They root quickly in a frame with bottom heat if damped and shaded on bright days. When rooted I find they do best on a shelf near the glass on the north side of an intermediate house. The plants are soon afterwards carefully separated, and placed singly in small pots, using light sandy soil, and when grown in genial heat soon attain to a good size, and are prepared for planting out in early summer.—PONICA.

HARDY FRUIT GARDEN.

Protecting Fruit Trees in Blossom.—If choice bush and cordon Apples, Pears, Plums, and Cherries can be readily protected when in bloom from the inclemency of sudden frosts, winds, and rain, this should be done. It is possible to provide temporary arrangements which will support tiffany or scrim canvas. Cordons growing against walls may have an arrangement of stout poles placed in the ground in front of the trees, the upper ends resting on the coping. Stretch and secure the protecting material over these. Bush trees should have poles placed round them, meeting together above the trees, where they may be fastened. The material for protection can thus be easily wound round the trees, and as readily removed. Horizontal cordons are conveniently protected by having a light wooden framework ready to place over, on which could be permanently tacked lengths of scrim or tiffany.

Peaches, Nectarines, and Apricots ought still to be protected on cold,

frosty, or stormy nights, continuing until the young fruits are a fair size, and receive the protection of the leaves.

Strawberries.—*Planting.*—There is still time to plant any varieties which have been wintered in nursery beds or bought in late. It is not desirable, however, to allow such late-planted beds to produce fruit, but rather encourage free growth throughout the season, nipping off all flower trusses when they appear. If plants can be lifted and placed in position with plenty of soil attached to their roots, such plants, especially if strong, might bear a small amount of fruit the first season. Weakly plants would be exhausted by this treatment. Allow all, however, to give indications of flowering, as by this means their fruitful character is proved. Those which do not flower the first season seldom do so afterwards, remaining barren, fruitless, and useless. Plant firmly and mulch down each side of rows with littery manure.

Feeding.—Established beds of Strawberries need a little special assistance to stimulate growth. Soot dusted among the plants helps to destroy slugs, and as it becomes washed to the roots affords nutriment which they can appropriate. A dressing of nitrate of soda, 2 lbs. to the rod, given when the weather is fairly dry, is soon absorbed by the soil, and directly used by the plants. As it specially stimulates growth, nitrate of soda ought not to be employed for young plants, which can be sufficiently well nourished by properly prepared soil, and usually grow strongly enough owing to bearing little or no fruit. Those which are benefited most are plants likely to produce heavy crops. Liquid manure may also be given.

Mulching.—The advantages accruing from a mulching of farmyard manure at the present time will be apparent in two ways. First, the soluble parts of the manure will be washed into the soil, assisting the plants to a considerable extent when the crop most requires extra support; second, the insoluble or strawy portions of the dressing, being washed and dried clean by the exposure, afford subsequently a clean bed for the fruit to rest upon when ripening. In order to secure these advantages the manure employed should consist mainly of that from horse stables, composed of equal parts of short manure and nearly fresh long litter, placing the mulching between the rows during this month.

Raspberries.—Remains of the mulching placed between the rows in autumn ought to be raked off the ground now. Lightly point up the surface with a fork, but not deeply, owing to the mass of fibres which ramify near the surface. Deep or careless digging with a spade would sever and destroy these. The effect of mulching regularly is to bring the feeding fibres close to the surface, and frequently the soil is so permeated with them as to render even pointing with a fork difficult to carry out without spoiling some rootlets. In such cases loosening the soil is unnecessary previous to applying a dressing of rich manure around and between the stools.

Newly Planted Fruit Trees.—All trees which have been planted in the course of the previous month require attention in staking and tying to prevent them being moved about by the wind. They should be secured well but not too tightly, either with tarred string or copper wire, but some strong pliable material ought first to be wrapped round the stems to prevent abrasion of the bark.

A mulching of light, not rich and heavy, material will be required on the approach of hot weather to conserve the moisture in the soil. Mulching is not, as in the case of old-established trees, for the purpose of feeding or supplying additional nourishment, but merely to regulate the temperature and moisture. In some soils, either now or shortly, water may be necessary to stimulate root action. A proper mulch applied to moist soil prevents the rooting medium drying too quickly; hence watering will be deferred until there is less danger of lowering the soil temperature.

Another matter of importance is pruning. There are few trees newly planted which do not require some amount of shortening. Shapely, well-formed trees, furnished when planting with abundance of roots, may only require the leading shoots cut back to well-placed wood growths. Others, with few roots and not having the required number of branches, must be more closely pruned, always to wood growths, pointing in the direction the branches are required to extend.

FRUIT FORCING.

Figs.—*Early Forced Trees in Pots.*—Increase the ventilation when the fruit shows signs of ripening, and expose to the sun as much as possible. The drier atmosphere encourages the Fig trees' worst enemy—red spider, and also brown scale; therefore, no effort should be spared to have the foliage clean up to ripening time. Supplies of water are needed through all stages at the roots, yet less when the fruit is ripening than during its swelling. Increase the ventilation at 70°, affording air constantly during the period of ripening. Day temperature 80° to 85° from sun heat, and night temperature 60° to 65°.

Succession Houses.—Trees in inside borders will need abundant supplies of water, and those in narrow borders and carrying heavy crops of fruit require liquid manure, with rich surface dressings. Attend frequently to tying in, thinning, and stopping the shoots at about the fifth leaf of such as are required to form spurs, and avoid overcrowding the growths. Maintain a night temperature after the leaves have become full sized of 60° to 65°, and 70° by day, allowing a rise to 80° or 85° from sun heat, ventilating from 70°, closing at 80°, so as to rise to 85° or 90° afterwards.

Late Houses.—Syringe the trees on fine days sufficiently early to allow of their becoming dry before night. Ventilate freely in the early part of the day, strive to secure solidified growths, and close early in the afternoon

with a fair amount of atmospheric moisture where there is means of excluding frost, but in unheated houses afford moderate moisture only.

Pines.—Carefully avoid a soft, drawn, and weakly growth in young plants in course of preparation for fruiting by dispensing with fire heat as much as possible, relying on sun heat. Maintain the temperature at 60° to 65° at night, and 70° to 75° by day artificially. This is sufficient to sustain the plants in a steady progressive growth. Commence ventilating at 75°, gradually increasing it with the temperature to 85°, keeping it through the day at 85°, 90°, or 95° from sun heat, with abundance of air. Close at 85°, but not so as to greatly raise the temperature. Sprinkle the paths lightly at closing time, and syringe the plants moderately about twice a week. Examine each plant before water is given, and when needed, supply sufficient to moisten the soil down to the drainage.

Fruiting Plants.—Those swelling their fruits are assisted by judicious applications of liquid manure, to be withheld when ripening commences. Stake the fruit to keep it in an erect position. When the suckers of fruiting plants become large enough, screw out the hearts of those not required for stock; one, or at most two, should be retained on a plant. The temperature ought to range in fruiting houses from 70° to 75° at night, and 80° to 95° by day. As the fruit ripens the plants may be removed to a cooler house, and the fruit will then keep sound for a lengthened period.

Vines.—*Early Houses.*—Where the Grapes have commenced colouring, give the border a thorough supply of water where needed, and mulch with rather short material. A little air should be left on constantly, so as to allow of a circulation, and prevent moisture from being condensed on the berries. When the Grapes are fully ripe, only afford sufficient heat to prevent the temperature falling below 60°, maintaining a moderate amount of moisture for the benefit of the foliage. If the weather prove bright, a light shading will assist Hamburgs in retaining colour, allowing moderate lateral extension.

Succession Houses.—Thinning the bunches and berries requires early and close attention, as every surplus bunch or berry kept longer than is necessary to make a selection of the best takes from the ultimate size and finish of those left for the crop. Likewise in disbudding and stopping, every needless growth is only so much wasted energy. It is not good practice to allow more foliage than can have full exposure to light and air. Borders require plenty of water, and weakly Vines improve wonderfully with tepid liquid manure. Avoid, however, a sodden and sour condition of the soil, as this leads to indifferent colouring and shanking.

Vines swelling their crops should have a moist atmosphere, damping the house two or three times a day and at closing time with weak liquid manure. Syringing the Vines, except for special purpose, is best avoided, as the water generally leaves a stain. Admit a little air early, increasing it with the advancing temperature, and maintain it at 80° to 85° through the day from sun heat; close early, so as to raise to 90° or more, and admit a little air at the top of the house before nightfall. This prevents moisture accumulating on the foliage, and is a safeguard against scorching. A temperature of 60° to 65° at night and 70° to 75° by day is sufficient from fire heat.

Late Houses.—The thick-skinned varieties of Grapes are now making rapid progress, and require attention in disbudding. As soon as the best shows of fruit can be distinguished, stop the shoots one or two joints beyond the fruit where the space is limited. Pinch the laterals at the first leaf above the bunch, and remove those below, except from the two lowest joints, which pinch at the first leaf, and sub-laterals also stop to one joint of growth. This treatment is best where the Vines are restricted to space. Where the bearing shoots are a good distance apart it is advisable to let the laterals above the bunch extend two or three joints, or until the space is covered with growths, then keep them well in hand. Close the house early in the afternoon with sun heat, maintain plenty of atmospheric moisture by frequently damping the house, and syringe the Vines at closing time, but not after the bunches show. Bottled Grapes in the fruit room should be examined twice a week for decayed berries, and bottles must be duly supplied with water. Keep the room as cool as possible.

Young Vines allowed to break naturally, and assisted with a little fire heat when the buds have grown about half an inch, make rapid progress; but they need not have a higher temperature than 50° to 55° at night, and 60° to 65° by day after the leaves appear, relying mainly on sun heat, with gentle warmth in the pipes on cold days. Remove all buds except one at each break, retaining the strongest, and leave the shoots about 18 inches apart on both sides of the cane. Crop permanent Vines lightly, but supernumeraries may carry full crops.

A STARLIGHT BOUQUET.—A greater anomaly in combination than that could not at the first glance well be perceived; but it is simple enough when explained, and a substantial fact. It means a new kind of toilet soap, on which Messrs. Lever Brothers of Sunlight fame have long been engaged in perfecting. They tell us the results of their experiments in producing an article of elegance and usefulness have exceeded their most sanguine expectations, and ask us to tell others. The Starlight tablets sent are certainly beautifully finished, firm and glossy, and are beyond question more fragrant than half the bouquets which are made of real flowers. After a trial by an experienced judge, the verdict—short and sweet—was as follows:—"Ornamental, serviceable, and delicious." It is of course open to challenge by all who like to test the matter for themselves.

THE BEE-KEEPER.

SEASONABLE NOTES.

THE month of March is usually noted for the many changes that take place in the weather, and the past month has been no exception to the rule. Fine sunny days were experienced during the first half of the month, the temperature on the whole being high, but though the days were bright they were usually followed by frosty nights. The latter half of the month was boisterous in the extreme. High winds, accompanied by sleet, hail, and snow, kept the bees confined to their hives, and the country had the appearance of mid-winter. The snow, however, soon disappeared under the influence of a higher temperature, and was followed by a downfall of the much needed rain.

The rainfall during the first three months of the year is phenomenal, as only slightly over 2½ inches have been registered. There is much headway to be made up before there is sufficient moisture in the land, but as the barometer is low, and the weather still changeable, there is a prospect of a heavier rainfall during the present month. The frosty nights and cold boisterous storms have had the effect of retarding vegetation. The meadows, which a month ago were as green as they often are in May, are now as brown as at midwinter. This is a fact that should not be lost sight of by bee-keepers, as the bees will require attention for some time to come.

The early blossoming of the fruit trees, which at one time appeared likely, has received the much desired check, and with the exception of the early varieties of Plums, which were fast bursting their fruit buds, nothing in my garden has suffered. Although they were only partly open the bees were hard at work on them during short spells of bright sunshine. Pears are at a standstill, and are not forward enough to have received injury from the late inclement weather. Had it continued fine they would now have been in full bloom, and the first frosty night would have destroyed them, so that they would have been of no benefit to the bees. Apricots, which are usually the first fruit trees to open their blossoms, have not bloomed earlier than usual. The mild winter does not appear to have affected them in the same degree as other fruit trees.

WHENCE POLLEN IS OBTAINED.

It is impossible for bees to increase in numbers without a supply of pollen, either natural or artificial, as it is used in conjunction with honey for feeding the young bees. If pollen can be obtained from a natural source it is decidedly better than the artificial article, which is usually composed of pea, lentil, or even ordinary flour may be used. In the former instance the bees collect it from the various flowers, and it is stored by them either at the time of gathering, or whilst on the wing in what is termed the pollen-basket situated on the third pair of legs. It is surprising the quantity of pollen used in a strong colony during a season. We have little doubt that if it were possible to obtain the weight it would amount to as much as the surplus of honey stored. Bearing this fact in mind, bee-keepers will see the advantage to be derived by having their apiary within easy reach of early midseason and late-flowering pollen-producing plants, shrubs and trees. It is not possible for all to be in this favoured position, still with a little forethought it is possible to assist the bees in this respect by planting suitable kinds for that purpose. When pollen is scarce and the bees are seen to visit the flowers without obtaining any, it is good practice to place a little flour in the flowers, and the bees will take it freely.

POLLEN-PRODUCING FLOWERS.

As has been shown the advantage to be derived by having a good supply of pollen near the apiary, it may be of interest to bee-keepers to know what flowers produce the most pollen at this season. First and foremost we would place the common Palm Willow. It is one of the earliest and best pollen-producing trees known in this country, and will last for several weeks in good condition. All the *Salix* are good for this purpose, but none of the others is as good as this variety, and bloom later in the spring. They are not particular as to position, but, as is well known, they succeed well in a wet situation. The common Box tree is also excellent for the bees, as at the present time they are blooming freely, and are a mass of pollen, on which the bees work. The Box tree does not bloom in a young state. *Pyrus japonica* is a mass of bloom, and is much frequented by the bees.

Among plants may be mentioned *Arabis alpina*, which will grow and flower freely in any dry spot, and should be planted in quantity where it is possible, as the bees work on it freely, and it has the advantage of lasting a long time in bloom. Wallflowers, too, will soon be a mass of bloom, and many other occupants of the flower garden. Fruit trees will doubtless be earlier than usual, so that there will be no lack of flowers for the bees.—AN ENGLISH BEE-KEEPER.

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8, Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Abnormal Calceolaria (F. A. D.).—The flowers are rather prone to change by the suppression of some parts or the multiplication or malformation of others. Your specimen had the moisture extracted from it to such an extent by the cotton wool that it was quite shrivelled. So far as we could comprehend its original character the flower represents a case of both suppression and malformation. There is no accounting for such freaks in flowers.

Ixoras (J. W. T.).—The soil generally employed for these beautiful stove plants consists of about two parts fibrous peat, one each of loam and good leaf soil, with a free sprinkling of bruised charcoal and sharp sand. They require brisk heat and moisture during the growing period, careful watering to maintain healthy root action, and topping with judgment, some requiring a longer time to develop flower trusses than others. More detailed information shall be given in an article, for which we hope you will not have very long to wait.

Asparagus (Young Grower).—You will find that to insure the best results it will be necessary to have the rows at least 18 inches apart, and the plants 15 inches asunder in the rows. The plants should be placed astride a ridge formed by taking out a small trench on both sides of the line at an angle of about 45°, and if the sharp edge is rounded a good seat for the plant is secured, placing it so that the crown will be 2 to 3 inches below the general level. Spread the roots straight in the trenches, cover with soil, and make moderately firm, then place the soil over the crowns. The plants should not be more than two years old, for nothing is gained by planting older; indeed, good one year's plants are the best. The blanching is effected by placing soil from between the rows over the crowns in early spring, which is removed after the cutting is completed, leaving a depth of about 3 inches only.

Canker in Fruit Trees (N. Tavistock).—The subject of canker has been many times and fully discussed, also illustrated, in the *Journal of Horticulture*, of which you are, perhaps, a comparatively modern reader. The active cause of canker in Apple, Pear, and some forest trees, is a fungus, though there is a form caused by a mite. Attacks are induced by the condition of the trees. Those which are in a thoroughly healthy state, root and branch, the wood well fortified by mineral matter gathered from the soil, and the leaves clear and stout, through development under direct exposure to the sun—such trees are not prone to canker. Very old trees may be said to canker because they are old, and have long since abstracted the requisite nutriment from the soil. When young trees canker they are either in an ill-fed debilitated state, or in a gross succulent condition—plethoric, through the roots penetrating a deep and, perhaps, wet medium, deficient in the constituents which are essential to sound growth. Succulent stems are injured by frost, though the scar at first may be unobserved, yet shrinkage occurs, and the fungus spores find entrance. With a multitude of fibrous roots permeating the upper layer of soil, and this containing phosphates, potash, and lime, kept moist in summer by a covering of manure, trees are seldom infested with canker. Prevention rests in sound cultural methods. Remedial measures must be in accordance with actual state of the infected trees. If growing robustly they may require root-pruning, if enfeebled need generous root nourishment, and the affected plants dressed with paraffin emulsion or Stockholm tar. A clear description is requisite of particular trees—their probable age, character of growth, weak or strong, with an indication of the nature of the soil and site in which they are growing,

for the purpose of giving advice that would be applicable under the circumstances.

Red Spider on Early Forced Vines (Journeyman).—Red spider generally appears more or less on all early forced Vines. Thoroughly cleansing the house and removing the loose surface soil prevents a large amount of after trouble. After trying almost everything, we have found nothing comparable with an insecticide containing soap, applied at a safe strength on the first appearance of the pest, with a brush or sponge. Sulphur applied to the hot-water pipes heated to 170° or more, gives off fumes that annihilate red spider, white fly, and spores of fungi, but sometimes injure the tender skins of Grapes, and therefore sulphur must be used with care. Plenty of liquid manure at the roots, with due supplies of atmospheric moisture arising from light mulchings of sweetened horse droppings, are inimical to red spider.

Calla Leaf Spotted (W. W.).—The very fine leaves, barring the brown spots round the edge here and there, and the minute white specks over the surface, account for the production of the splendid spathes. There is no disease in the leaf, and yet we find no trace of their presence, or of their having been there, beyond the minute silvery marks which occur on the common Arum leaves very decisively, and have been referred to as occasioned by oxalate of lime. We have found the mixing of a little air-slaked best chalk lime with the soil, about 2½ per cent., to counteract the tendency, probably due to organic acid in the soil. The discolouration and shrinkage are due to moisture resting on the parts affected, not necessarily from being placed thereon, but in consequence of the parts being in contact with other leaves, though it may occur without either by transpiration in consequence of the vigour, this moisture hanging on certain parts, and causing the destruction of the tissues. We have found a little air constantly, thus allowing of both transpiration and the evaporation of the moisture, the best, if not only, preventive. It is hardly possible to grow the plants without such brown spots under ordinary circumstances, but we have had to produce them without spot on leaf, and found nothing serve so well as the "crack" of air constantly. Care must also be taken in handling the plants, as the least bruise on a young leaf edge develops into a brown patch on the margin by the time the spathes are perfected. We are obliged for the charming Roses.

Sir Watkin Narcissus Bulbs Diseased (G. C.).—We found two forms of "grubs" on the moist parts of the bulbs, but they were considerably dried in consequence of your misdirection of the parcel. It was despatched on March 28th, but did not reach us until nearly midnight on Saturday, April 2nd. The creatures were in the decayed scales, and are—1, a small white worm of the family Enchytræidæ, quarter-inch in length, and, viewed under a pocket lens, white or silvery in appearance; it has thirty segments, and of setæ (bristles) two or three per bundle. The name of Enchytræus argenteus, Mich., was given to it on account of its silver colour, and though commonly regarded as a saphrophyte certainly leads a parasitic mode of life, attacking various outdoor plants, such as Asters (causing them to wither suddenly when coming into flower), Mignonette, and various bulbs. We have also found it in the decayed parts of several plants grown under glass. It appears to cause the decay of the living bulb scales by working in the dead ones, and from these passing to the parts beneath, already browned and injured by contact. We have not found it in living tissue, but its action between the bulb scales is unquestionably the cause of the decay. 2, A small, dirty yellowish-white grub, three-sixteenths of an inch long, with a black or dark brown head and dark brown caudal segments, legless, but with small hairs or bristles on the segments. It is the larvæ of the St. Mark's fly (Bibio Marci), often very destructive to the roots of various garden plants, especially Ranunculi and Narcissi. We have found several hundreds at the roots or bulbs of Daffodils. The fly generally appears about St. Mark's Day. The larvæ of the insect chiefly live on decayed matter, but on bulbs work between the scales and set up decay, speedily destroying the bulbs or great part of them. The fly is a very curious two-winged creature, and very active, the female having an ovipositor, and uses it for depositing eggs in the crowns of the bulbs, even entering cracks in the soil to get at them. The larvæ hatching work their way in the decaying scales, and by the ferment cause the decay of living matter, thus providing themselves with available nutrition similar to maggots in the living flesh of sheep, and also allied species in the tissues of plants. You ask for a preventive and remedy. We have found three more or less effectual. 1, Fir tree oil insecticide, following the instructions. 2, Soluble petroleum made by dissolving 1½ lb. of softsoap by boiling in a gallon of water, then whilst hot, but removing from the fire for safety, adding three wineglassfuls of paraffin oil, and stirring briskly until amalgamated. This is diluted to 12 gallons with hot water, and applied when cool enough by means of a rose watering-can to the ground, previously loosened at the surface to prevent running off, and using 1 gallon per square yard. 3, Little's soluble phenyle, a wineglassful to 3 gallons of water, applying in the same way as 2. The latter gave the best results as regards after growth—1 in 240 fluid measure did not injure the Narcissus foliage, which is smooth, hence not, like Cucumber and Tomato leafage, easily injured. Any of the three will kill both the "whiteworm" and the "grub," if these are reached. The following chemical fertiliser is also advised:—Bone superphosphate, dry and crumbly, 5 parts; muriate of potash, 80 per cent. purity, 3 parts; and sulphate of ammonia 2 parts, mixed, 4 ozs. being used per square yard over the whole surface of the beds when the foliage is dying down. The mixture must not be used over growing plants, and if the bulbs are very near the surface (ours were 4 inches deep) only half of the mixture may be applied at one time. There is no waste of the fertilising substances if pointed in lightly, but if rain follow soon after the dressing there is no need of pointing in.

Destroying Woodlice (Novice).—You will find it an excellent plan to get some old boards, sprinkle one laid on the floor or bed with a little oatmeal or crumbs of a floury boiled Potato, and another board of the same size placed upon it, with a small stone at one or both ends, so as to keep the board sufficiently far from the lower one as to admit the woodlice. The vermin will soon find out the food, when it is a matter only of removing the pebbles and crushing the woodlice between the boards. Some persons use the old boards only, which, partly decayed, attract the woodlice, and they are swept into boiling water, or it can be poured on the boards. We have seen thousands destroyed in the manner indicated.

Echeveria retusa (J. W. W.).—This plant is very useful for winter flowering. Easily increased and cultivated it occupies a place amongst the best of market plants in winter. The flowers are bell-shaped, much larger than *E. secunda*; orange red, very bright and rich outside, the inner surface being yellow. They are borne in a two-branched inflorescence at the extremity of the stem, the two branches curling slightly downwards. Plants in 5-inch pots are most useful and produce several flowering stems, the blooms lasting for a considerable time in good condition. A rich light loam and well drained pots are needed to insure success, and plants are best prepared by growing them out of doors during the summer, lifting and potting them in the autumn, when they can be transferred to the conservatory or greenhouse. The species was found by Mr. Hartweg growing on rocks near Auganguco, Mexico, and was first received from him by the Royal Horticultural Society in 1846.

Luculia gratissima (A. W. P.).—The culture of this fragrant flowered plant is very simple, but it is averse to a superabundance of water or the least approach to stagnation at the roots or in the atmosphere. Therefore a porous soil must be provided, composed of loam, peat, leaf soil, sand, and a few pieces of charcoal, thoroughly incorporated; and whether the plant be in a pot or a border the drainage must be well attended to. When growing freely, or about to flower, weak liquid manure may be occasionally supplied with advantage. Propagation is effected by taking cuttings of the young firm wood, with a heel of the old wood attached, and inserting them in similar soil to that already described, employing rather more sand. They should be placed near the sides of the pots, the latter being plunged in good bottom heat and covered with a bell-glass. When the cuttings are rooted shake them out carefully, and pot them singly in thumb or 3-inch pots, afterwards increasing the root-room as the plants advance in growth, but being careful not to overpot them. When thoroughly established they may be grown in any cool or intermediate house where the temperature is not allowed to fall much below 50° at night at any period of the year.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (W. Taylor).—If the seeds sent from India resembled small dark Sweet Peas, but much harder, the plant is undoubtedly an inferior form of *Canna*. It is popularly called Indian Shot, from the purpose to which the seed has been put by natives of India. (S. C.).—1, *Cornus mascula*; 2, *Asclepias curassavica*; 3, dead. (T. J. R.).—1, *Rhododendron hirsutum*; 2, *Erica codonodes*; 3, *Berberis aristata*; 4, *B. Darwini*. (Amateur).—1, *Asplenium bulbiferum*; 2, *Adiantum pedatum*; 3, *Selaginella Kraussiana*. (F. P.).—1, *Dendrobium Fortunei*; 2, *Lycaste Harrisoni*. (J. R.).—1, *Cydonia (Pyrus) japonica*; 2, *Medicago lupulina*; 3, *Sedum azoideum variegatum*; 4, *Abutilon vexillarium*; 5, specimen insufficient, send when in flower. (M. J. S.).—1, A good form of *Odontoglossum crispum*; 2, *Vanda suavis*; 3, *Odontoglossum triumphans*. (E. G.).—*Bifrenaria (Lycaste) Harrisoni*, an exceptionally good form. (B. B.).—*Iris japonica*, synonyms *I. fimbriata* and *I. chinensis*.

THE FARMER AS A CITIZEN.

THIS is not going to be an agricultural paper, so we warn those readers who only care for agriculture pure and simple of what this week they may expect. Our farmers form a considerable class, and in the rural districts find that if they would do their duty to their neighbours they must take upon themselves many offices outside their own work. "Outside" is perhaps a wrong word to use here, for nothing can be outside their own work that bears on rural economics. We know there are men who shirk their responsibilities, and men who do that on the plea of urgent home work are usually those who are slack even in that work.

The busiest man is the man of the most leisure, and is the man who is always ready to help lame dogs over stiles, while he manages to get his own work done well and in good time.

Take an ordinary English village in a Wheat-growing district; the farms vary from 200 to 600 acres, and are held by an aged farmer a little out of date; his son, is far readier to find fault than to help in any scheme of amendment; a man who ought to take a lead in the parish, but is of an indolent turn, and owing to family difficulties has placed himself rather out of things; another risen from the ranks, but born before education, even in its rudimentary branches, was considered a necessity; another holding with his farm a licensed house; a young man of promise who is at present troubled with natural shyness; and another who practically does all the work of the parish at home and abroad.

The duties of this man would be much lighter if he could persuade some of his neighbours to take office with him, but by common consent they look to him to see them through all difficulties.

Of what does parish work consist? That is a wide question, and varies according to the parish. We may reasonably begin with education. In the villages there are few Board schools. The schools are voluntary, with a board of managers—probably the squire or parson is chairman. In some cases there is no resident squire, and the parson, good man though he may be, has no notion whatever of business. There is a great deal of routine business to be done—i.e., of a clerical nature—and difficulties are constantly cropping up, if not with the head master, with some of his subordinates. A well-managed school is an admirable institution—master, scholars, and ratepayers all receiving the maximum of benefit. Then, again, we may reckon with the new technical education. A leading spirit is necessary here to plead wants and requirements before a central board, and to plan work at home.

This must involve at least four meetings yearly at the central offices, to say nothing of meetings in the village. Most villages have a sanitary board; this is, however, usually merged in the Parish Council. Now, there has been a movement on the part of farmers to ignore these Parish Councils, and to hold themselves aloof. This is neither wise nor prudent. Granted that the powers of the P.C. are happily limited; yet it is well that those limited powers be used to the best end. We have no wish to decry the mute, inglorious Milton, or the village Hampden; but we do wish sometimes they had a little better notion of business procedure, and would not waste valuable time in useless, aimless discussion.

A good, popular farmer is certain of election as chairman to such a body, and he can by tact and management prevent the whole thing becoming a farce. Then there is the office of overseer of the poor—this does not carry great responsibilities, but there is work which it is necessary to perform in a business-like manner. Where a good farmer shines is on the District Council, but he must have a good stomach for work, and infinite patience. He is not only guardian of the poor, but also guardian of the rates. He remembers that while the poor in receipt of parish pay are in no enviable position, there are many ratepayers who have a terrible struggle to make ends meet, and present a decent appearance to the world at large. Their pockets should be as sacred to him as the comfort of the pauper.

Unless a man has been in office and has proved himself of good business habits, he little knows what work may be put upon his shoulders. Once a fortnight is board day, when the work of the different parishes in the Union is considered. Once a fortnight is held the rural district meeting, which deals with highways and manifold business. We saw an agenda paper yesterday with twenty items for consideration—some, of course, are dismissed in a minute or two, others are long and tiresome questions. Assessment meetings are no sinecure, but members of that committee are only (or ought only to be) picked men. The questions brought before them are so wide and so far-reaching, and involve so many interests, that it is only capable men who stand a chance of doing the business properly. Then for other meetings; who attends finance committees, educational questions, boarding out, and house visitations?

We know of men who never all the year round escape a single week, and who to their credit attend with amazing regularity. Barren honour is all they get, and we fear often a bit of abuse. Of course there are some minds who thoroughly enjoy all business details, but even with them the flesh must often be weary. Sir Edmund Verney, in an article in a March magazine, fairly abuses the farmer for frequenting so many markets. He either does not know or is wilfully ignorant as to who attends to all these details of local government.

We have an instance of one farmer who was for years chairman of a board of guardians in his union. Ten miles in, ten miles out every Wednesday, fair weather or foul, and on those days he had no opportunity for doing his own business, as his union town presented no facilities for transaction of business, and so every Saturday he had another ten miles' drive in an opposite direction.

Most farmers, too, are expected to take an interest in the local affairs, and so forth; and if the individual farmer does not benefit

personally he cheerfully works in the interests of others. We have said nothing of any political organisations, but as they exist all through the country the farmer must of needs be associated more or less with some working committees.

WORK ON THE HOME FARM.

We have often to repeat ourselves; but new readers require the information, and old ones sometimes forget. After this bitter blast warm bright days are sure to follow, and it is well to look over young stock—i.e., calves in boxes or pens. In cold weather these animals need good, rich food; but as soon as the weather changes, unless the diet be restricted, the calf will do too well, and may probably fall a victim to black-leg. Remember, it is the best animal that first succumbs. A change to the open yard and plain food will do away with any risk.

Foaling mares should be carefully watched. Gently worked exercise is fine to keep them in healthy condition.

If the land (arable) be too wet to allow of horses on it, it is not a bad plan to brush-harrow grass fields, and possibly there will never be a "slacker" time. Some of us have still a few Turnips left, and the hogs are getting fat and heavy. It is an annoying thing to find in the morning in the fold a good hogg "over cast," and drawing its last breath. A visit by lantern light is a wise precaution. It is advisable now to sow a few Tares, one of the most valuable of fodder crops.

Wheat or Oat stubble is the proper course, and to get a good plant use plenty of well decayed fold-yard manure—say at least twelve loads per acre. "Thousand-heads" as autumn food for lambs might now be sown. Lambs find a good deal of difference between a well ripened plant and one that is immature, and it does not do to keep them waiting till their food is ready. Here, again, plenty of manure and phosphate of lime on a deep cool soil are a desideratum.

We may now reasonably hope for a better butter supply. The shepherd, having put his lambs fairly under weigh, is not requiring so much new milk to supplement that of the ewes as he did during last week's cold and storm.

SUGAR-BEET GROWING IN ENGLAND.

THE attention of agriculturists in many parts of the country has been recently again directed to the question of the cultivation of sugar-Beet. In the course of a letter just addressed to the Central Chamber of Agriculture, the Board of Agriculture stated that they "do not consider they would be justified in proposing to the Treasury that they themselves should institute any further experiments with regard to the cultivation of sugar-Beet; but if the Council think it advantageous at the present time to encourage those agriculturists to do so who can afford to take the risk of sowing small areas, the Board would be willing to co-operate with the Council so far as to place the services of their officers at the disposal of the Council, with a view to the preparation of a model form for recording the various details connected with such experimental growth, although the season is probably now too far advanced for any material changes to be made in the scope and character of the experiments which are to be instituted during the current year. At a later stage the Board would also be willing to consider whether they could properly afford the Council any assistance in bringing the results of any new experiments to the knowledge of agriculturists generally."

REMARKS.

27th.—Overcast, with almost continuous rain or drizzle till 5 P.M.; dull and damp after.
 28th.—Dull and drizzly early; overcast day, but a gleam of sun at 1 P.M.
 29th.—A few spots of rain in afternoon, but generally fine, with a good deal of sunshine.
 30th.—Fog early, and frequently hazy during the day, but sunshine almost throughout; fine night.
 31st.—Bright sunshine almost throughout.
 1st.—A little fog early; bright sun all morning, and generally in afternoon.
 2nd.—Fine and generally sunny.
 Warmer towards the close, and on the whole nearly an average week, but rain still deficient.—G. J. SYMONS

WILLIAMS' SHADING MATERIALS.

THE MOST SUITABLE FOR
SHADING ORCHIDS, FERNS,
PALMS, and STOVE and
GREENHOUSE PLANTS

It is a strong durable Cotton Netting, woven in squares so close as to exclude the direct rays of the sun, but admitting the greatest amount of light attainable through shading.

Blinds made up
and Fixed
Complete.

It withstands the weather better than any other class of Shading, and may be beneficially used on account of the thickness of its texture, during cold weather, to keep the frost out. The leading Orchid and Plant Growers in the country have used this material for some years, and speak very highly of it, pronouncing it to be the very best material for plants they have ever used.

Sold in pieces 30 yds. long by 1½ yd. wide, price 40s. each. Samples submitted gratis.

This new Shading is in the form of a white powder, and is prepared for use by applying boiling water to the compound, and allowing it to cool, when it can be applied by means of a brush. It dries instantaneously, and can be rubbed off easily when moist. This Shading may be used for GREENHOUSES, SKYLIGHTS, WINDOWS, &c.

Sold in 1-lb. packets, with directions for use, price 1s. each. 1 lb. free by parcel post for 1s. 3d.

WILLIAMS' "EUREKA" SHADING. Regd. 2 lbs. free by parcel post for 2s. 4d. Each packet will make half a gallon of shading material when mixed. It is a great improvement on anything hitherto offered, and lasts the whole season.

B. S. WILLIAMS & SON,
Victoria & Paradise Nurseries,

1898-FORBES' CATALOGUE-1898

(Over 150 Pages, nearly 150 Illustrations)

Of FLORISTS' FLOWERS and HARDY BORDER PLANTS, is got up regardless of trouble or expense, with the result that it is by unanimous consent pronounced the most comprehensive, most accurate, most reliable, most complete, and best extant.

It gives full and accurate descriptions of everything in the way of Florists' Flowers, also colour, height, time of flowering, and price of all the best Hardy Border Plants, together with their English or common names, and a mass of other valuable information that cannot be had elsewhere.

It is, in fact, a veritable reference book, invaluable to all growers of these plants, and should be in the hands of all intending purchasers. FREE ON APPLICATION.

JOHN FORBES, Nurseryman, Hawick, Scotland
ESTABLISHED 1870.

No. 929.—VOL. XXXVI., THIRD SERIES.

Eckford's GIANT SWEET PEAS

Direct from Raiser. 30 GOLD & SILVER MEDALS. Everybody should have ECKFORD'S priced descriptive CATALOGUE, containing CULTURAL NOTES, &c., gratis and post free, from HENRY ECKFORD, WEM, Shropshire. Eckford's Culinary Peas also lead, see Catalogue.

PLANTING SEASON.

DICKSONS Nurseries (450 Acres) CHESTER.

LONDON FERN NURSERIES,

LOUGHBOROUGH JUNCTION, LONDON, S.W.—Ferns, large and small, in variety; Aralias, Grevilleas, Cyperus, Ficus, Ericas, Palms, Dracenas, Aspidistras, Hydrangeas, Pelargoniums, Fuchsias, Marguerites, Crotons, &c. Trade, send for Wholesale List. Special List for Amateurs, send for one.—J. E. SMITH.

ASPARAGUS.—This delicious vegetable does not require half the expense usually incurred. For simple instructions see SEED LIST, free on application. Strong roots from 2/6 per 100.—RICHARD SMITH & CO., Nurserymen and Seed Merchants, Worcester.

IMPORTANT TO MUSHROOM GROWERS.—CUTHBERT'S SPECIALITE MUSHROOM SPAWN. Always alike; most productive. Hundreds of Testimonials. Per Bushel, 5/-.—R. & G. CUTHBERT, Seed, Bulb, and Plant Merchants, Southgate, N. Established 1797.

H. DUNKIN, Victoria Nursery, West Humberstone, Leicester, can supply grand plants of CALCEOLARIAS, yellow or bronze, at 8/- per 100; LOBELIA Emperor William, 4/- 100, strong plants for dividing; TOMATOES, ready for planting out, 2/- doz. Cash with order.

100,000 BEGONIA TUBERS.—Large, erect flowering. Single, 12 for 2/3; 100, 16/-. Double, 12 for 2/6; 100, 17/-. SEND FOR LIST, FREE.—JOHN WELLS, Begonia Nursery, Ryarsh, Malling, Kent.

HEATING APPARATUS.—Medals 1875 and 1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2/6; post free, 2/10.—JONES and ATTWOOD, Stourbridge.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the Journal of Horticulture: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—HIRST, BROOKE & HIRST, Ltd., Leeds.

PROTECT YOUR GARDENS—Garden Netting, oiled and dressed; will not rot if left out in all weathers. 100 yards by 1 yard, 3/-; 100 yards by 2 yards, 6/-; 100 yards by 3 yards, 9/- Or so on to any width. Carriage paid on all orders over 5/- I do not require payment till you have received and approved of the netting from—HY. J. GASSON, Garden Net Works, Rye.

ALL WHO WISH GRAND RESULTS should use THOMSON'S IMPROVED VINE, PLANT and VEGETABLE MANURE. This Valuable Manure is yearly growing in public favour. Can be had of all Nursery and Seedsmen, or direct from the makers, WM. THOMSON and SONS, Ltd., Tweed Vineyard, Clovenfords, Galashiels, N.B. Price Lists and Testimonials on Application. 1 cwt. and upwards Carriage Paid to all stations in Britain and Ireland. London Agent—Mr. J. GEORGE, 14, Redgrave Road, Putney. Agent for Channel Islands—Mr. J. H. PARSONS, Market Place, Guernsey. Also THOMSON'S SPECIAL CHRYSANTHEMUM MANURE. ½ cwt. Carriage Paid to all stations in Britain and Ireland.

Journal of Horticulture.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St. London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

MISMANAGED FRUIT BORDERS.

IF borders are constantly mismanaged, it is not to be expected that trees rooting in them will long remain in a fruitful condition. Unfortunately no hard and fast lines can be laid down as to the proper treatment of fruit borders, so much depending on circumstances. At the same time some instruction has to be given, more especially as to when to water or to apply liquid manure; but amateurs do not seem to thoroughly understand what is meant, with the result in some cases of neglecting to attend to these important details altogether, while others not infrequently do too much watering and too little thinking, their crops not being a complete success accordingly.

From the commencement to the end of the year's working—that is to say, the production and maturation of crops and wood—the borders ought never to be found in a dry crumbling state. Treat the borders exactly the same as the soil, supporting the roots of Vines in pots, and no mistake will be made. When the soil is approaching dryness is the time to water, no matter at what stage of growth the Vines or other fruit trees may be. Caught at the right time comparatively little water is sufficient to well moisten the soil, but if neglected till the border becomes quite dry it will be found a very difficult matter to properly remoisten it, added to which many root fibres will have perished, and progress will be unsatisfactory. I do not agree with those growers who point with pride to the water passing out of the drains connected with inside fruit borders, for I am of opinion that if the borders are watered at the right time they can be properly moistened without the drains being brought into requisition at all. This I have repeatedly proved in bygone years, and at the present time neither the Vine nor Peach borders that are doing me good service have any more drainage than was afforded when corn was grown on the same land. What will happen when the roots have reached the subsoil? would be a fair question, and which I will anticipate. Is it so very certain that the roots will find their way to the subsoil to any great extent? My aim is to make

No. 2585.—VOL. XCVIII., OLD SERIES.

things agreeable near the surface, and if any roots forsake good living for a cold berth and slow death, let them do so.

We may easily err in putting off watering too long, and also in being in too great a hurry to apply moisture to the roots. Occasionally, what may appear a somewhat light soil may hold water like a sponge, and unless very carefully treated becomes sour and injurious to the roots. When Vine leaves present a sickly appearance the probable cause is an excess of water at the roots. I would rather see them a bluish green colour, owing to dryness of the border, than yellow from stagnation, the former recovering quickly when the remedy is applied, but not so the over-watered Vines. It is far from my wish to frighten the inexperienced. On the contrary, I am writing with a view to inducing them to act and think for themselves, adopting common sense, not rule of the thumb, practices.

The poorer the borders the greater the need for watering often. At the same time I do not believe in constantly drenching the soil with water, which may or may not be lower in temperature than the border, if it can be avoided. Timely top-dressings with rich compost, followed by a mulching of strawy manure, will save the hose or watering-pot considerably, and both ought to be applied annually. Not a few inside borders have to serve as floors of houses, and I have seen scores of them as hard and apparently as dry as a road. The firmness of border is not so very objectionable, always provided the soil can be kept moist. Root fibres innumerable are formed in firm, moist, and not too poor ground, the loose rich root-run favouring the production of long fibreless roots. It is not yet too late to take a neglected inside border in hand. If roots are to be found remove the dry, hard surface soil down to these, leaving the ground loose and level on the surface to facilitate the next operation of well moistening the whole of the reserved portion of the border. The following day apply a top-dressing of loam, manure, burnt earth, ashes, fine mortar rubbish, and a sprinkling of bonemeal. If only a few half-dead roots are found not far away from the stems, prune them and relay in fresh compost. Mulch with strawy manure or peat moss litter not too fresh from the stable. Keep the old and new soil uniformly moist, and the chances are roots will soon be attracted to the surface. Pure fresh leaf soil and also the residue from a slow garden fire are likewise root-inducing, and may be used for mulching or top-dressing with advantage.

We may reasonably assume that few borders are in the plight just indicated, but there are many which are mismanaged, if in a lesser degree. Some cultivators are decidedly averse to the use of a fork on a border. What if a few surface roots are broken occasionally? The good done by loosening a hard surface occasionally more than compensates for any little temporary damage done to the roots, and as a matter of fact it is scarcely possible to thoroughly moisten a somewhat dry border unless the surface is loosened prior to the application. Then obviously manures are wasted on hard surfaces, the greater portion of each dressing being washed away.

This brings me to another portion of my subject—viz., the application of manure to fruit borders under glass generally, much of the foregoing applying to Peach, Fig, Cherry, and other borders with the same force as it does to those occupied by Vine roots. Surface dressings of slowly dissolving chemical manures are doubtless of service, and I have good reason to speak highly of some of the special Vine manures that have long been in commerce, but for real effectiveness commend me to liquid manure in a weak state—little and often is my motto. The roots are incapable of appropriating large quantities of anything other than nearly clear water, and may easily be injured by an overdose of manure. Large numbers of fruit borders are too rich already, this remark applying with the greatest force to the Vine borders on which so much labour and expense have been expended, and if these are watered and manured to excess they soon become distasteful to the roots. With manuring as with watering no rules can be laid down that apply to all borders alike, and much must be left to the judgment of individuals.

Worn-out old borders and the poorer new ones are naturally the least capable of supporting Vines or trees in their efforts to produce heavy crops of fruit, and it is all such that should have the most

assistance in the form of liquid manure, additional to the rich top-dressings already recommended. Instead of waiting till the crops are well advanced towards maturity, feeding at the roots should commence in the case of poor borders from the first. Liquid manure may be safely and effectively applied in a moderately strong state before the roots are active, and weaker nearly every time the borders require moistening afterwards.

When the crops are about fit to gather harm might result from an application of liquid manure to the roots, but directly they are cleared off, or while the foliage continues to perform its natural functions, liquid manure may be applied with advantage. Thus treated trees and Vines have their strength more or less recuperated, and are likely to remain highly profitable for many years in succession.—W. IGGULDEN.

HINTS ON TOMATO CULTURE.

TOMATOES are readily raised from seeds, which are best sown during March in pots or pans not too thickly. Most cultivators perceive the necessity of securing strong seedlings, and therefore do not err in crowding them unduly. They require to develop in the seed pots until rough leaves commence to appear. It is then time to place each either in a small pot or four round the edges of 3-inch pots, in order that they may strengthen and form roots freely. The stems of the seedlings should be sunk low in the soil. The next move must be to single pots, again sinking the plants as low as possible. This is an important means of keeping them dwarf and sturdy until potting or planting finally. The last-sized pot before the latter operation is carried out should be 5-inch, this being most convenient in every way.

It is essential that the plants be kept on dry and airy shelves in a position close to the glass in a greenhouse or frames, as attempts to hurry growth in heat, moisture, and shade will produce unsatisfactory plants. Abundant light and air constitute the two main requirements, and must be provided and continued in every stage of growth. As the plants advance in size it will be evident that strict attention should be given as regards water, so that they do not suffer; and it may be necessary to examine them twice or thrice daily when the soil becomes well permeated with roots. It is also essential to carry out the potting firmly, thus inducing roots, fibrous in character and plentiful in quantity, instead of being coarse, strong, and less numerous. The latter induces growth of a strong but succulent nature, the former promotes equally strong but sturdy and short-jointed growth. Flower trusses may commence to form before the final potting, but this signifies little, even if fruit forms.

For fruiting in pots 11 and 12-inch size pots are the best. Place a few crocks over the drainage holes and cover with pieces of substantial turf, lightly dusted with soot. The compost should be of a substantial holding nature rather than rich and light. Use turfy loam four parts to one part decayed manure. Should the loam be poor, add a sprinkling of bonemeal and wood ashes, mixing all well together. If turfy loam is not procurable employ that with little or no fibre, insuring its porosity by freely intermixing some powdered brick. Good vegetable soil may also be used with successful results. In potting place very little soil in the pots before introducing the plants, which ought to be well furnished with roots, but not badly pot-bound; in fact, they ought to be in such a condition that a shift into larger pots is desirable in any case. Place the soil around in layers, making each firm with a potting stick before adding more.

The compost as well as the ball of roots ought to be neither wet nor dry, but in an intermediate state of moisture. Should the soil and the roots be too dry it will be a difficult matter to properly moisten them after the potting is completed without saturating the fresh compost to an extent which may cause sourness before the new roots can enter it. On the other hand, the sufficiently moist ball of roots and compost being favourable to quick root action, this is soon evident. Add no more soil than will just cover the ball half an inch. Firm potting at this last shift is very desirable. A large amount of material can be compressed in a small space when rammed down, and as this method of potting acts well with Tomatoes, favouring short-jointed growth and fruitfulness, it must not be omitted. A very important reason for having the soil in a moist condition is that water will not be needed for a short time, but of course much depends upon position and weather. The soil and roots must not become too dry, however, before applying sufficient to moisten the whole.

As soon as growth commences, the shoots, which quickly spring from the axils of the leaves, ought to be rubbed out, continuing to do so as they appear on the extended growth. Confine each plant to one

main stem, and either train upright to a stake or to a wire under the roof of a lean-to or span structure.

Cultivating Tomatoes in pots requires that the attention given be very regular, and that growth takes place in the full sunshine near the glass as far as practicable. When the nutriment in the soil has been freely extracted by the mass of roots, top-dressings of soil of a rich character must be applied, this being done as often as roots appear on the surface, and the pots admit of the soil. When this is not conveniently practicable, additional sustenance can be afforded by applications of liquid manure, also sprinklings of artificials, washing the latter in with clear water. Much may be done by systematic feeding to continue the extension of the plants, the setting and swelling of the young fruit at the same time that the advanced part of a heavy crop is being brought to perfection.—E. D. S.

VEGETABLES FOR HOME AND EXHIBITION.

KALES.

THOUGH Borecoles do not come within the exhibitor's category to the same extent as others previously mentioned, they are indispensable in any garden, whether large or small. Hardy in character and robust in habit, all that Kale requires is a fairly retentive soil, an adequate supply of manure, and a sufficiently long season of growth to insure sturdy maturity before severe weather sets in. Success lies chiefly in having strong healthy plants ready to take the place of early crops as ground becomes vacant. There are few gardens in which space can be kept purposely for this crop, nor is it necessary if care and judgment be exercised.

Gardeners must be always looking ahead, and with winter greens it is a mistake to delay the sowing till the ground is ready to receive the plants, by which time is lost, as they are only attaining to planting size in the seed beds when they should be establishing themselves in permanent quarters. On the other hand, it is an error to begin too soon, or the plants are liable to be spoilt through overcrowding in the seed bed whilst waiting for the vacancy they are intended to fill. Fortunately Kales are more accommodating than some other green vegetables, and do not suffer to the same extent from the latter cause, yet thin sowing and prompt removals are golden rules, and if the best results are desired they must be closely adhered to.

Generally speaking two sowings of this crop are sufficient for the requirements of most gardens, the first to be made about the middle of March, and the second in April, though the exact dates are determined by locality. Previous notes on the sowing of green vegetables are applicable to Kales, and the scattering of wood ashes in the seed bed acts as a preventive against root troubles. Forethought is necessary in transplanting, and the earliest plants, if ground be vacant, should be removed in June. As Kales remain longer on the ground than other winter greens, planting in the most favourable positions that will be wanted early in the spring for other crops should be avoided, otherwise the plants have to be pulled up at the time when they are most useful. In small gardens where it is necessary to economise space, it is advisable to plant Kale and other winter greens between rows of second early Potatoes. In order to be successful in this method a variety of somewhat dwarf close habit should be chosen, and the rows of Potatoes must be 30 inches or a yard apart. Though it is preferable to plant in showery weather, Kales are of such a tenacious character that even in the driest weather they rarely fail to start if water is applied after planting. All plants should be in their permanent quarters by the middle of July, because if left till later they have little chance of becoming established before the advent of winter.

Variegated Kale is sometimes grown for decorative purposes, and the tinted forms in conjunction with the natural curl of the foliage find favour in some places. Asparagus Kale is probably the first of the family in point of flavour. It is very hardy, and produces a profusion of sprouts which in the late winter and early spring are very acceptable. The next two for quality are the Cottager's Kale and Dwarf Green Curled. The hearting or cabbaging Kale is a useful variety, producing Cabbage-like heads. There are several other varieties of long standing, and of taller and more robust habit, which may be grown if quantity is the prime consideration; but where quality is first looked for, as it should be, then the dwarf compact growing kinds, such as those mentioned, are the best to grow.

Another vegetable belonging to this section is the Kohl Rabi, which is generally of more interest to the farmer than the gardener. It has been many times recommended as excellent for table, but the plant has made little headway as a garden vegetable. There is no difficulty about its cultivation, and if sown in March and transplanted in June its requirements are few, and at some tables the young fleshy Turnip-like stems are appreciated.

Kale is sometimes exhibited in collections when other vegetables are getting scarce, and for this purpose whole stems of a close-growing

compact variety are the best. It is not as an exhibition vegetable that the Kale is dwelt upon in the foregoing notes, but rather to remind growers of the attention that is needed for the welfare of one of the most useful of winter greens.—GROWER AND JUDGE.

ALLAMANDAS AND THEIR CULTURE.

THE species and varieties of the genus *Allamanda* (so named in memory of Dr. Allamand of Leyden, who first communicated seeds of this genus to Linnaeus) are elegant (so called) climbing evergreen stove plants. Not any of the species or varieties, however, possess means of climbing—neither tendrils nor stem appendages giving them claim to the title, hence it rests solely on the freedom of growth of the shoots. Besides, at least one—namely, *A. nerifolia*, is a shrub. More, all *Allamandas* are naturally (or so grown as to be semi-evergreen, or practically) deciduous.

Allamandas are of comparatively easy culture. *A. Chelsoni*, *A. Hendersoni*, *A. nobilis*, and *A. Schottii*, with *A. cathartica* and *A. Wardleana*, if variety be wanted, trained to roof trellises fixed 6 to 9 inches from the glass, are gorgeous by the beauty of their foliage and flowers during the summer months. Trained so that the shoots have full access to the light, crowding being avoided and the growths kept from touching the glass by timely attention to tying loosely to the wires of the trellis, the plants produce flowers of great substance in vast profusion, which for cutting purposes are most valuable. The flowers, however, do not last long in a cut state, yet sufficient for table decoration, and an *Allamanda* table, with a setting of their own foliage in contrast with hard-grown *Adiantum cuneatum*, can hardly be excelled. If not wanted for such purpose as temporary decoration, the shoots may be allowed to ramble in a somewhat natural manner, and thus seen more or less depending in a rather thinly disposed manner, *Allamandas* in full floral array present a unique appearance.

The flowering depends on the solidification of the wood; hence the roof system of training results in the greatest floriferousness. *Allamandas*, however, are required to be portable, so that when in their prime they can be transported to hall, corridor, or staircase, and on occasion exhibited. For these purposes the plants are grown in pots, and the shoots trained to formal trellises of various shapes. Here, again, light proves the chief factor in securing a floriferous habit, the growths being allowed to spread out to the sun till the flower buds appear, and then the tying-in has to be done. *A. Chelsoni* marks its bateness of the process by snapping, *A. Hendersoni* not being much less resentful of tying-in; also, *A. Schottii* lets it be known that careful diversion from a natural course is imperative. Still, excellent specimens are grown on formal trellises, *A. grandiflora* being one of the most accommodating, and in well-grown examples very beautiful. *A. nerifolia* naturally forms a bush. It is about the only species that admits of spray cutting; hence this practice gives the plant a continuous blooming habit, for, given plenty of light, it thus pushes flowering growths successively, and, though not equal to the others in size and beauty of flower, deserves a place in the stove for that purpose. It is also hardier than the other species, consequently bears conservatory and other decorative use with little, if any, impairment. Indeed, it succeeds in a lower temperature, a point of some importance in small establishments.

PROPAGATION.

Allamandas are easily propagated by cuttings almost at any time of year, but the spring or early summer, when the old plants are pruned or the growths become rather firm, is the usual time. The top of the shoots comprise the parts selected, each cutting having two or three joints, removing the leaves from the lower one or two. Place each singly in a small pot, using a compost of sandy peat and sand in equal proportions, press the soil firmly around each cutting, and water moderately, the soil being fairly moist to begin with. Plunge the pots in a propagating bed having a bottom heat of 75° to 80°, attend to shading and watering, and in three or four weeks they will have emitted roots, and have made some growth. Then raise the pots out of the plunging material, and if in a propagating frame gradually inure to the air of the house, standing the pots on the surface of the bottom heat bed.

In a fortnight or three weeks' time the plants will have filled the small pots with roots, and must be transferred to 5-inch pots, and again stood on the propagating bed. The moisture constantly arising from the bed along with the gentle warmth facilitates growth. When the roots have got hold of the fresh soil, as indicated by the starting into vigorous growth, pinch the point of each plant intended to be grown on a trellis. This will result in the buds left, or some of them, starting, and when the new shoots have made two joints take out their points. When the pots become filled with roots the plants should be shifted into others 2 inches larger in diameter, and this may be again followed up as fast as the plants fill the pots with roots. Likewise the stopping of the shoots may be followed up two or three times in the

course of the summer, early spring propagation being practised, thus forming a good foundation for the future trellis-trained plant.

In the case of plants intended for training up rafters or over roof trellises do not pinch the leader, and if this divides select the best shoot, cutting the other away; also pinch side growths at the first joint, or rub them off whilst quite young. This will throw the vigour into the one shoot, and the leaves being retained it will become stout and pushed forward. Provide a stake if necessary for support. Shift into larger pots as the roots fill the respective ones, and when the plant has the stem required pinch out the point of the shoot. This will give the foundation growths for covering the trellis, these being from time to time stopped to secure an even basal formation. Grafting is done in the spring, using ripened wood as scions, operating by whip grafting, and covering the wounds with grafting wax. The stock may be any free-growing variety easily raised from cuttings.

COMPOST.

The plants succeed well after first being well rooted in a mixture of three parts good fibrous loam, and a part each of "nuts" charcoal, coarse river sand, and decayed cow manure or leaf mould. Such, thoroughly incorporated, answers either for borders (which need not be more than 3 feet wide and 18 inches deep over a foot of drainage) or for pots. When forming the border make the compost firm, and in potting the plants make the fresh soil firm round the old ball, loosening the sides of this and removing some of the old soil. Always leave room in potting for plenty of water, as the plants, when in active growth, require a liberal supply, alternating once or twice a week with good liquid manure. After the first year the plants require but one potting each season, which should be done soon after the buds have started to grow afresh in the early spring. When the plants are in as large pots as can be given, the ball should be reduced about one-third all round, and at the bottom, so as to allow of fresh compost under (with perfect drainage) and around the part retained, this not being deferred beyond the starting of the buds, and not much in advance of it. Plants in borders simply require some of the old soil removed, and fresh supplied in its place each year.—G. ABBEY.

(To be concluded.)

BLACKS IN POTATOES, AND "BLUES" IN THE RAISERS.

BOATRACE time has come and gone, but a bad attack of blues surely remains. In reading the communication by "Experimentalist" on page 276, I thought of the unhappy raisers who there fall under the lash, and sympathised with them in their trouble. The writer of this weird production wanders over the Potato fields of the past half century, smiting around him lustily, but when his performance is over I am irresistibly reminded of the terrific onset of Raphael Aben-Ezra, who, led on by Synesius, fell on the foe with fury, but after belabouring half a dozen or so without causing them the slightest inconvenience, found himself at length with his head beneath his feet on the field of battle.

One of the first things that must strike the discriminating reader is that the writer of the article on "blacks" is a master in the art of providing the "open door." He begins by telling us that he has been familiar with the trouble for over fifty years, and ends by tacking it on to muriate of potash. (How much of this ingredient was used in 1844, by the way?) But between the year named and 1898 he has likewise kept a watchful eye on larvæ, scorpion flies, and other suspicious characters, so that if an unwary critic challenges him on the manure question, the "Experimentalist" can fall with righteous indignation on the mysterious but offending "fly," and straightway run it in.

Now, while your correspondent is deciding the knotty point as to whether the black trouble has arisen from a "stab" or an "eye gone blind," other people, who are interested in the larger question of the production of heavy crops of well-flavoured Potatoes, will be asking themselves (1) Whether there is real ground for the attack made on modern sorts? and (2) What substantial basis has been advanced for condemning acid fertilisers wholesale.

I will deal first of all with No. 1. I did not happen to be born in 1844, but I do happen to know the three varieties which the writer singles out for special mention. What form of Ashleaf, I should like to ask, has higher qualities than Webber's White Beauty? The Old Ashleaf is its equal in flavour, but does not yield more than half the crop. Coming to Lapstone, what chance would that always weak and long since worn-out sort have with Duke of York if both were tried together at the present time? Lapstone was a popular Potato twenty-five years ago, and if it is not a popular Potato to-day it is because we have better—i.e., more suitable varieties. Duke of York is as fine in flavour as Lapstone was, as early, a heavier cropper, and of better constitution.

Coming to the York Regent, I unhesitatingly say that, good

as it was at its best, we have in Windsor Castle a variety not one whit inferior in quality, and in every way more reliable. Taking general merit into account in the case of a late Potato, I should like to ask, what old sort approaches Up-to-Date? It is the modern Potato *par excellence*, having a tough hardy constitution, respectable flavour, and magnificent cropping and disease-resisting powers. Let "Experimentalist" experiment a little more, and before he jumps at the conclusion that Lapstone and York Regent have never been equaled, try the quartette I have named—grand Potatoes every one.

Your correspondent raises the familiar bogey of injurious acidity in connection with muriate of potash. He also attributes the "blacks" to it. To be sure it slips out that the villainous "blacks" were there just the same when the muriate was not used; but what of that? When you want to establish a case you need not worry about such trifles as consistency and recognition of plain facts. It is easier to get on without them. It chanced, however, that I have been experimenting with Potato manures rather freely during the last few years, and, will you believe it? a muriate manure is the very best I have found. Let me just give the result of one careful trial, as typical of the general results.

The comparison was between (1) a dressing of good farmyard manure at the rate of four loads per 20 rods (one-eighth acre).

(2) The same with a mixture (B) of 3 lbs. superphosphate, 1½ muriate of potash, 1½ nitrate of soda, and 1 steamed boncflour per square rod.

(3) The same (farmyard manure) with a mixture (C) of 3½ lbs. superphosphate, 2 kainit. and 1½ sulphate of ammonia per square rod.

Not I alone, but everyone who saw the plot, was struck with the great superiority of No. 2. The ground was one of a large number of allotments in a field, and it was significant and instructive to hear allottees, who scorned the very word artificial, begging to know where "that there B stuff could be got."

It seems to me that "Experimentalist," as Mr. Thomson said of me a short time back, confounds things that differ. His advice to drain hollows is right enough, especially if an outlet can be found for the water. I quite agree with him, also, as to the time in certain cases. But, then, the advice on these scores is equally applicable whether natural or artificial manures are used. Damp, water-logged land will give bad Potatoes just as abundantly when stable manure is used as when artificials are employed. It is not the latter which do the mischief, but the unsatisfactory mechanical condition of the soil. Nothing can balance the latter evil. It must be remedied first of all, as experience has taught me full well.

Having got the soil in a sweet and friable state, let the Potato grower try the following briefly sketched plan:—Item 1, work under his top spit a moderate dressing (25 to 30 loads per acre) of good manure; item 2, apply 7 lbs. per rod of the B (soon to be re-christened the Pea!) mixture, preferably all except the nitrate in January, the latter at the first earthing; item 3, use seed not less than 2 and not more than 3 ounces in weight; item 4, include in the list of sorts Webber's Beauty, Duke of York, Windsor Castle, and Up-to-Date; item 5, avoid overcrowding, especially with the last-named; item 6, send the result to the Journal.—W. PEA.

GREEN VEGETABLES.

THE present time is that which is best suited to the sowing of most kinds of seeds of the Brassica family, and an open situation will produce the best plants. There is no comparison between plants thus raised and those sown near high walls and hedges, and all drawn in one direction by the shade and solar influences. Thick sowing is one of the greatest evils, and must be guarded against most carefully at all times. Such choice varieties as Magnum Bonum, First Crop, and Autumn Mammoth Cauliflowers give the best results when sown in pans at whatever date, afterwards being pricked out on beds prepared by treading on a hard surface about 4 inches of well decayed manure, and placing on this sufficient soil in which to prick out the plants some 4 inches apart. When planting time arrives they are each cut out in a square piece with a sharp knife and suffer no check, therefore good heads are sure to follow in rich soil if water is given to the plants until they become established.

Of Broccoli, that indispensable and popular variety, Veitch's Self-protecting, is well worthy of the best culture, and in a winter and autumn like what we have lately come through, with Superb Early White and Snow's Improved Winter White there has been no lack of good Broccoli. Model, Leamington, Knight's Protecting, and Late Queen are all desirable varieties for later supplies. Improved White Sprouting or Purple Sprouting are also serviceable where large quantities are called for, and one of these should be included in all collections. Of Kales, Curled Scotch, of which A1 is a fine strain, Asparagus, Cottager's, and others are best sown from the middle to the end of April. Rosette Colewort, Tom Thumb Savoy, and Miniature Marrow Cabbage should be sown towards the end of May, also early in June, and these small yet excellent varieties are of the greatest use where every foot of land is required to keep up a supply of good vegetables.—C. F.

PHALÆNOPSIS JOHN SEDEN.

THOUGH this hybrid is by no means new, having received a first-class certificate from the Royal Horticultural Society in 1888, it attracted much attention when it was staged at the Drill Hall by Messrs. J. Veitch & Sons some weeks ago. It was raised from a cross between *P. amabilis* and *P. Luddemanniana*, and is certainly one of the handsomest of the hybrid *Phalænopses*. Referring to *P. John Seden* (fig. 63), Williams' "Orchid Growers' Manual" says, "Of all the hybrid *Phalænopses* raised by Mr. Seden this is undoubtedly one of the finest, and has deservedly been dedicated to its raiser. The flowers measure 3 inches across, sepals, petals, and lip ivory white, covered over the whole of the surface with minute dots of purple." It is a chastely beautiful flower, that is certain to receive the praises of everyone who sees it.

NOTES ON PHALÆNOPSIS.

THE present is a good time for a thorough overhauling, cleaning, top-dressing, repotting or basketing wherever necessary of these beautiful Orchids. Considerably more care is necessary with these than with the ordinary distichous-leaved kinds, not only on account of the roots being easily injured, but also because these plants are very easily incommoded by disturbance of any kind. A sudden drop in the temperature is injurious, and for this reason it is not wise to take the plants to the potting shed unless this structure is properly heated, and care is taken in the transit of the plants to and fro. Usually a temporary bench may be rigged up in the house, or a portion of the stage can be cleared, and this prevents the possibility of a check.

Many of the plants will, of course, be in flower in a large collection, and these will not be pulled about until after the blossoms are past; but all others that require attention may be seen to. Where the baskets or pots, cylinders, or what not are sound and large enough for the plants, these will not, of course, be taken out of them; but all the sour, decayed, or unsuitable portions of the compost will be picked out or driven out by a forcible jet of water from the syringe. Most of the roots will be bared in the process, and all that are dead will be cut clean out, carefully avoiding at the same time any injury to the sound ones.

The hard material used may also have become somewhat heavily charged with moisture, if not actually sour, and any pieces not having roots attached may be removed, and new clean pieces substituted. Beyond these nothing but a little sphagnum moss is necessary as compost, and this will be used in a greater or less quantity according to the habit of the species and the size of the individual plant. In every case it is better rather under than over done, as the moss naturally keeps alive in the moist heat of a tropical Orchid house, and would soon become too thick.

The cushion of green moss is indeed a great help to the cultivator, for it acts as a moisture conductor to the roots, and is the best index to the state of the compost. In replacing the material carefully avoid leaving it in such a way that the moss and crocks shift about, as when the plants are taken down for examination or dipping, the roots may be just taking hold of a loose piece, and are snapped off short to the detriment of the plant. Bring the surface of the moss up in a neat cone-shaped mound, the top of this coming just under the base of the plant, and trim off all ragged ends, these if left making it difficult to determine the true state of the compost as regards moisture.

While the plants are in hand they may be thoroughly cleaned if any suspicion of insects are present, for it must be kept in mind that these lovely Moth Orchids are very sensitive and easily injured thereby; and, moreover, their dislike for sprinklings renders them peculiarly liable to insect attacks. The vaporising fumigators have done wonders towards making Orchid growing a success, for one always felt a disinclination to use tobacco smoke for these plants whenever the other method is as safe and harmless in its action as it is effectual in killing the insects. The only care necessary is to take out of the house any plants in bloom, for the texture of all Orchid flowers is very susceptible to injury, as witness the havoc wrought by fog in and near the metropolis.

The atmosphere of the house after the plants have been put to rights at the root should be kept very moist, and it is a good time to slightly

increase the temperature, for no matter how carefully these necessary cultural operations are gone about, there always is, and always must be, a slight check consequent upon them. The slight rise, too, at this time of year is quite necessary in the ordinary course of events, for it will be noticed that both roots and top growth are on the move and the season of activity has commenced.

In everything connected with their culture, gradually altered conditions are more conducive to success than sudden changes, and a rise of a few degrees in the course of a week or ten days is better than pushing it up all at once. Watering at the root deserves a passing notice. When much disturbance has taken place, the root will have lost the power of gathering moisture to a certain extent, and a limited supply will be necessary. Thus the necessity for a moist atmosphere will be apparent, for whether or not there is absorption through the foliage, it—the abundant moisture—will certainly check too rapid evaporation.

Wherever it has not been done, the shadings must be put in order, and for *Phalænopsis* there is nothing to beat the lath blinds that are advancing in favour with orchidists. The chink of light between the laths allows the quickening efforts of the sun to be felt by

FIG. 63.—PHALÆNOPSIS JOHN SEDEN.

the plants; but the rays do not stay long enough in one particular position to do any harm by burning or scorching, as it is termed. Though for *Odontoglossum*, and some others of the very coolest section, these blinds may admit rather too much sun to allow of the temperature being kept down to its proper limit, for all heat and light-loving tropical kinds they are a capital invention.—H. R. R.

BEET.

BEET is indispensable in all well managed establishments, being in request at almost all seasons of the year; for salads, garnishing, and general use, it is the most valuable of any of the tap-rooted salad vegetables. Where large quantities are called for, and that to extend over the greater part of the year, several sowings are necessary to have roots that are tender and of the desired colour. The Turnip rooted variety is the one that arrives at maturity in the shortest time, and an early supply may be had by sowing in a warm position early in April on a rich mellow soil, while for succession one or more long varieties may be sown, as these are usually more popular than the Turnip rooted. One of the best varieties for this sowing or for later use is Cheltenham Green Top, while those who prefer roots of a darker hue would do well to select Sutton's Dark Blood Red and Middleton Park Favourite. A late sowing should be made the last week in May, and in some seasons this may turn out the best crop of the whole of the sowings, producing moderate sized, well shaped roots.

The ground must be well worked, and if possible a good dressing of wood ashes mixed into the soil when digging, taking care to incorporate these well up with the soil, and by taking small spits this is easily done. For exhibition, Pragnell's is one of the handsomest and brightest, and should be grown on soil heavily manured the previous year. Beet follows well after Peas, Celery, or any of the Brassica family. On light and sandy soils the crop will be much benefited by a light sprinkling of salt, taking care, however, that it does not come directly in contact with the growing plant.—C. FOSTER, *Doddington*.

IDEAS FOR BEDDING.

It may appear premature to write about bedding, but the air of activity in the potting shed and propagating houses gives evidence that for some time past it has been thought about. The bright days of the early spring find gardeners more than usually busy, as there seems so much that requires attention at the same time. Bedding is certainly not the business it used to be, as the methods have changed, and fashion now demands something more varied and elegant than the straight lines and acute angles of the old school. This change has, on the whole, proved beneficial to gardeners, as it has done away with a portion of the nursing that took up so much valuable time and space. There is much about the old style yet that we cannot well dispense with, and when judiciously blended with what we may call the new, the best effects are obtained. Advocates for any one particular system are apt to let their enthusiasm run away with them, and frequently do we see instances of this.

These notes are suggested by two engravings of the same garden—one ancient, and the other modern—and both taken from the same point. The first, depicted in the days before photography became a fine art, shows the old style. Flower beds and ribbon borders are the principal features, and in the faintness of the picture can be discerned the boldest of the outlines of numerous carpet beds. Easy graceful curves are conspicuously absent, and straight parallel lines abundant. There is a clear-cut, made-to-order sort of look about everything which is carried from the groundwork of the flower beds to the surrounding Yews. Statuary is dotted about, and in the stiffness of the scene there appears no suggestion of ease and restfulness such as is usually associated with a garden.

The second picture clearly shows the changes brought about by modern ideas, though here and there may be seen the relics of the old intermingled with the new. Half the flower beds are gone, and broad expanses of turf are noticed in their places. Stately trees stand boldly conspicuous that are hardly noticeable in the first picture. Not, indeed, because they are not there, but owing to the multiplicity of surrounding objects they are almost lost in insignificance. There is just a trace left of the old fantastic shape of the Yews, but soon it will be gone. In the place of the geometrical designs in the flower beds, there is just enough pattern to make it discernible, and the rest is an undulating outline of surface. Some of the walks, too, have been altered, and gentle sweeps are shown in the place of right angles. Along one terrace, where figured a long rectangular bed by no means in keeping, are a series of round beds dotted in the turf, every other one having in its centre a bushy specimen of variegated Maple which—though the camera refuses to depict its colour—forms a bright relief to the dark green of the surrounding foliage.

In spite of the changes in forms of bedding there are several features discernible in both engravings, and one of them seems well in character both with the old and new. I refer to the pyramid "Geraniums," a method of cultivation by no means common in gardens, as in few establishments, except the one under notice, have I seen it adopted. It appears to be one of the old customs, that has to some extent lost itself in modern changes. The first requirement in forming pyramids is tall plants, and in most gardens there are "leggy" Pelargoniums that might well be utilised for the purpose. Small round beds running parallel to walks are good situations for pyramids, and they may also be placed at intervals down long borders, and thereby break the flatness that often prevails.

Suppose we have such a bed to furnish. A stout stake is first placed in the centre, and others that will bend are deposited in circular fashion within 6 or 8 inches from the outer edge of the bed, and about a foot apart. These are then compressed and securely fastened at the top to the centre stake. The framework is now laid, and the Pelargoniums are planted at intervals round, and the stems distributed evenly, and fastened to the stakes. In a few weeks the stakes will be entirely hidden by foliage, and the pyramid, furnished from base to apex with bright showy flowers, will continue to be attractive till later in the autumn. The taller plants should be placed in position first to cover the apex of the pyramid, the shorter ones being suitable for filling the base. A row of blue Lobelia or other dwarf flowering plant round the whole will add to the effect. In the autumn the plants may be lifted, potted, and stood along the back wall of a cool vinery or Peach house, where they can remain until again wanted for planting. So tenacious of life are Pelargoniums that they may be used for many years for this purpose. The trouble in commencement is getting plants tall enough for the purpose, and therefore "leggy" greenhouse plants should be reserved, though in choosing varieties thought must be given to colour and habit. In regard to the latter, robust growing sorts that are apt to make large leaves and produce few flowers are not much good, and should be avoided.

There may be those who are on the look-out for fresh departures in the forthcoming season, where the introduction of pyramid "Geraniums" might supply the want. They have been features in

some gardens beside the one referred to for many years, therefore there is nothing new about them. There are many things connected with gardening that are old, yet known to the comparatively few, and a great deal that bears the name of being original is but the digging-up of the dry bones of some good gardener's work, and infusing them with fresh life.—G. H. H.

PROFITABLE FRUIT GROWING.

It is not without some misgivings that I commence the task of lecturing upon this subject. Were it the profitable cultivation of one particular kind of fruit I should have felt more at ease, but profitable fruit growing is a subject as wide as it is important—a subject which has been studied by the greatest intellects of our times, and recommended as the sure panacea for the depression which has, and still affects the agricultural interests of this country. While others again, after giving the subject their consideration, and in some cases carrying out experiments, have come to the conclusion that it will not pay, I may as well here, and at once, give you my own opinion on the subject, after being connected with fruit growing one way and another for over twenty years, and it is that fruit growing in this country, either out of doors or under glass, or a combination of both, which is perhaps the best method, can be made a profitable industry. I do not say that at the present time, unless under exceptional circumstances, and exceptional ability is displayed, you will make a fortune, but I say that a good and comfortable living can be got, and the measure of success will be according to the measure of ability put into the business.

While saying this, I am well aware of the many disadvantages the fruit grower of the present day has to contend with, and which were unknown to our predecessors twenty years ago. Foreign competition, and over-production in some things at home, have brought prices down of late nearly 50 per cent. Four or five years ago, Grapes for instance, would, during December and January, bring 3s. per lb. Now the samples must be exceptionally fine to bring more than 1s. 6d. Foreign competition is getting keener every year. New and improved methods of storage are being employed, that now, such perishable fruit as the Peach, which we thought beyond the power of a distant grower to put upon our markets, are seen in midwinter retailing in our shops at 8d. each, and hailing from South Africa. Some of the finest of what we call hardy fruit are brought a distance of 4000 miles. We have to face competition from every quarter of the globe. Each year we hear of new lands in many distant parts being brought under fruit cultivation, principally for the British markets, and each year we see improvements in storage and fast transportation. The fruit grower of to-day and those who may think of starting this industry may make up their minds to face in the near future even lower prices for many things than what is the standard now. Still, with all this, I hold that British grown fruit can hold its own, and when properly gone about can be made to pay.

The best of our home produce still tops the market by a long way. No foreigner has yet been able to approach our home Grapes. What tasteless, insipid things foreign Tomatoes are compared to our own. I may here say that not only do Scotch Tomatoes command the highest price, but some that are grown in Ayrshire have maintained a record price during the last few years. I have seen these Tomatoes fetch 9d. per lb. when Covent Garden quotations were 5d. I have seen also at the same time, and in the same saleroom, hothouse Grapes sold by the cwt. at 5d. per lb., 4d. less than the Tomatoes. Strawberries cannot be brought long distances and maintain the rich flavour of fresh gathered fruit. The same could be said of many other things; even the splendid Apples which come to us in ever increasing quantities from across the Atlantic have not the rich flavour of our home fruit, and if we are here beaten by the States and Canada, as we undoubtedly are, it is because they are put upon the market in quantity of uniform quality and attractive appearance. Not that the fruit is itself superior in any way to the best that can be grown in this country.

I think the growth of the enormous trade in American Apples is very much the same as that of the Danish butter. We can say of Danish butter that it is good, very good, but it has not the real butter flavour the best home produce has, which still commands the top market price, but this best can scarcely be had. It has not been produced in sufficient quantity to supply the demand, hence the foreign has stepped in with a good all-round article, which has had no difficulty in displacing the inferior butter, which is still too common. It has been the same with the Apple trade. I will not say that in Scotland we will ever be able to compete with the Americans, but I cannot see why in many parts of England, if properly gone about—growing only the best sorts, and bestowing the same taste and care in gathering, grading, and packing as the Americans do—home growers should not be able to hold their own,

at least they might take a much larger share than they now do of supplying the people with this wholesome fruit.

I have said that fruit growing in this country can be made to pay. I have tried to show you what I daresay most of you already know, that many fruits can be grown in this country superior to and commanding a higher price than those of the foreign producer. Then why, you may ask, is there such diversity of opinion as to whether fruit growing is profitable or not? And why do we hear of so many failures? I suppose the answer would be, they failed for lack of knowledge, and to a certain extent this would be correct. Technical education, or rather the want of it, has been the favourite cry of late as the cause of our decline in other branches of industry besides fruit growing. Well, if technical education means the thorough mastery of all details bearing on a particular trade, I say it is a good thing. In fruit growing no great success will ever be attained without it; but in my opinion the things most wanted are a little more brains, a little more enthusiasm, more energy, foresight, and business aptitude, and above all a capacity for taking full advantage and acting upon the knowledge we already have by reading, observation, and practice.

It is not the knowing, but the doing that will ever achieve anything. For instance, what gardener but has known from the earliest years in his profession that if a fruit-bearing tree is healthy looking, but not fruitful, that in lifting or cutting its roots will in nine cases out of ten bring it into a bearing state? Yet we find thousands and thousands of trees all over the country in a fruitless condition, and allowed to go on from year to year. In how many private gardens do we find that if the produce of the trees covering, or rather about half covering, the walls were sold it would bring more than would pay for time and material to tie and prune them. It is sad to see such grand positions so unprofitable; but how can it be otherwise when we find borders in many cases composed of soil that has been there for perhaps a hundred years, and which are annually dug and sometimes trenched to within 2 feet of the wall. What can such trees do but send down strong wood roots to make strong unfruitful growth? Does every gardener not know that the more abundant the small fibrous roots of a fruit tree are the more abundant will the crop be if well fed? Yet how few act upon this knowledge in an intelligent way. No; it is not so much knowledge we need as a something to spur us up to do what we know should be done; something to give us more dash and go-ahead, more rooting out, pulling down and building up, more independent thought and backbone, a greater love for work—hard, intelligent, persevering work—putting as it were our best foot foremost, and depending on the strength of our right arm. This is what is needed. I have never yet heard of a case where a man possessed of these qualities was known to fail. These were the qualities of the men who founded some of the largest market establishments around London and the south, and who, mind you, had not the advantage of a gardener's training, but were brought up to and made their living at other trades and professions.

About the best and heaviest crops of market Grapes I have yet seen were grown in the north of England by a man who up to middle life had been a wheelwright. By far the largest and most flourishing market establishment in Scotland was started about ten years ago by a young man from a city office. Now he has nearly 10 acres covered with glass, grows annually close on 100 tons of Tomatoes, 60,000 pots of Chrysanthemums, and hundreds of thousands of other things. These men were enthusiasts, loved their work, and gave it their whole-hearted attention; and though they had everything to learn as they went along, and many failures and obstacles to surmount, by persevering hard work they were successful, as all who follow their footsteps will be.

(To be continued.)

CANKER AND PRUNING.

I HAVE been reading your remarks to a correspondent on canker in fruit trees, on page 314. From what I observed on the 6th inst., I feel inclined to ask if rough pruning is not one of the causes of canker? Standard Apple trees, about twelve years old, were being thinned out with a saw, and the jagged saw-cut left unsmoothed with a knife. In places the saw had gone nearly through the branch, which had then been either pushed off, or the branch was twisted, so that the bark was peeled off from 1 to 4 inches in length. The whole of these branches could easily have been removed with a sharp knife, which would have left the cuts clean, and the whole process workmanlike. The only use the knife had been put to was pushing its point into the stem just below the head of tree, and drawing it steadily down. Is not this a case of inviting canker?—R. C.

[Such rough mutilation, mis-called pruning, as that described, is pitiable, and affords direct means of access to the spores of the canker fungus (*Nectria ditissima*) to take possession of the trees. The spores, however, do not abound equally everywhere, and, moreover, we entertain a strong belief that all Apple trees are not in the same degree liable to invasion by the enemy. Sound cultural methods, intelligently carried out, are of the first importance in fortifying trees and plants against their attacking foes.]

WEATHER IN LONDON.—The Easter holidays may be said to have been passed in fine weather, notwithstanding the fact that we had some heavy showers, with a little thunder, on Saturday. Good Friday was a glorious day, the sun shining from an almost cloudless sky. There was a slight breeze that made the day very pleasant. On Easter Sunday there were one or two slight showers, but Bank Holiday was a beautiful day, being bright and warm until the evening, when it commenced to rain between seven and eight o'clock. On Tuesday it was cold in the morning but became warmer later. There was a high wind all day. On Wednesday it was genial and summer-like.

— **WEATHER IN THE NORTH.**—On the morning of the 5th inst. 7° of frost were registered, but there has been none since. The week was throughout one of April weather. Westerly winds have prevailed, showers have fallen every day, and the temperature has generally been high for the season. Vegetation has made a rapid advance, hedges and trees are tinged with green, and there is ample promise of fruit blossom. —B. D., *S. Perthshire*.

— **SOWING VEGETABLE MARROWS.**—I find the middle of April a suitable time for sowing the seeds, employing 3-inch pots. Place one crock at the bottom of each pot, over that a layer of fibry turf. Fill up with a rich compost of loam, leaf soil, and decayed manure. Make a hole in the centre with the finger, dropping in one seed, cover it, and make level. Use the compost moist. Stand the pots together in a warm house or vinery, shading with paper. A few light syringings with tepid water will probably suffice until germination ensues, when a position close to the glass must be afforded, and shortly afterwards a similar position in a cold frame.—E.

— **PROFITABLE FRUIT GROWING.**—This subject seems to be of perennial interest to all who are engaged in horticultural matters, and papers are frequently being read in different parts of the country at gardeners' meetings. Of the more recent ones that have been brought to our notice was that of Mr. Duncan Buchanan, Forth Vineyard, Kippen, which was read before the members of the Ayrshire Gardeners' Mutual Improvement Association on March 31st and April 1st, 1898. The essayist dealt with the subject in a practical, comprehensive, and exhaustive manner, and many valuable points were given that ought to be generally adopted. The *Ayr Observer* gives the text of the paper, which we are confident many readers would be glad to read, and we therefore reprint it in an abridged form, commencing on page 322 of this issue. The continuation will appear in an early issue.

— **WOLVERHAMPTON HORTICULTURAL CLUB.**—At a recent monthly meeting of above Club Mr. J. Martin of Messrs. Sutton and Sons gave an instructive lecture on the Gloxinia. In the course of his remarks Mr. Martin stated that the Gloxinia was introduced into this country in 1739, but not generally grown until about twenty years ago. The normal varieties and the fertilisation and selection which has given us the flower in its present improved form were described, and lengthy details were given as to treatment, both as regards the culture for decoration and for exhibition from the time of sowing the seed until the blooming, which he said can be easily done in six months. As to varieties, the lecturer recommended Her Majesty, Reading Scarlet, Azure Blue, and others. A good discussion followed, and questions were asked by members, to which Mr. Martin replied.

— **LONDONERS ON BANK HOLIDAY.**—There can be no doubt that Londoners as a class have a lively sense of the importance of enjoying their Bank Holiday, and the number of travellers by every available means of locomotion on those days is astounding. As a nation we are said to take our pleasures sadly, but the inventor of that thought would alter his opinion if he went to Hampstead Heath on either of the three summer Bank Holidays. Of holiday-makers 'Appy' Ampstead claimed, it is estimated, on Easter Monday upwards of 100,000. Other popular resorts are Kew Gardens, the Zoological Gardens, the Crystal Palace, Epping Forest, each of which was very largely patronised, while the day being so fine and genial, the seaside secured a heavy contingent. All the parks and commons were enjoyed by thousands of juveniles, and with neither these nor their elders can it be said that they were "taking their pleasures sadly."—SOUTH LONDONER.

— **PROPAGATING BLUE AND WHITE LOBELIAS.**—The old plants of Lobelias divided a few weeks since, and the divisions placed in boxes and pans, have grown so freely in the warm moist atmosphere of a vinery that stout cuttings are obtainable. These are most useful for increasing stock, as they root quickly in sandy soil under warm, moist conditions, forming nice plants by bedding out time.—E. S.

— **OUTDOOR SPRING FLOWERS.**—The present seasonable weather is suiting the Hyacinths in beds and borders, and they are making attractive displays in public parks and private gardens. Primroses and Polyanthus have advanced into flower rapidly since the month came in. The main display of Wallflowers will shortly be in full beauty. Double Daffodils brighten beds and borders, and the earliest Tulips are showing colour.—E. D. S., *Gravesend*.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of the Society, to be held at the Institution of Civil Engineers, Great George Street, Westminster, on Wednesday, the 20th inst., at 7.30 P.M., the following papers will be read:—“Anticyclonic Systems and Their Movements,” by Major H. E. Rawson, R.E., F.R.Met.Soc.; “Results of Observations on Haze and Transparency in 1897,” by the Hon. F. A. Rollo Russell, M.A., F.R.Met.Soc.

— **NOT A PARADISE FOR MARKET GARDENERS.**—Miss Sykes, in her travels through Persia with her brother, Captain Molesworth Sykes (Messrs. A. D. Innes & Co.), states that living in Kerman was by no means expensive, as meat and bread were under 1d. a pound, eggs ten a 1d., chickens 2d., a minute lamb 4½d., and all the ordinary articles of food in the same proportion. We paid 1d. daily for our vegetables to the old gardener, who rented the garden from our landlord, advancing to 2d. in the fruit season, when we consumed any number of Mulberries, Apricots, Peaches, Melons, Figs, and Grapes.

— **A REMARKABLE CASE OF CORRELATION.**—It has occurred to me that the following extract from “Nature,” March 31st, 1898, might interest especially some of the Pine Apple cultivator readers of the *Journal of Horticulture*. “A very interesting case of correlation is recorded in the Bulletin of the Botanical Department, Jamaica, for December, 1897. Particular attention has been paid lately to the selection of good Ripley Queen Pine Apples, and it is found that if there is a broad red stripe in the centre of the leaf, the fruit will turn out good; in other cases the fruit goes into holes at the bottom and is attacked by ants.

— **CHOU DE MILAN.**—On an allotment at Surbiton a week or two ago I saw a patch of this most useful hardy Kale, that I verily envied, it was so clean, green, and beautifully fresh, the spring sprouts, that form so delicious a product when well cooked, having pushed a few inches long. Striking was the contrast presented by the dark curled leafage of the tall and other Scotch Kales, so generally grown, for these were all more or less browned or burnt with fog, and were unfit for use; but, of course, the stem sprouts were yet unharmed. A more perfect piece of hardy Kale for the time of year I cannot hope to see, and I longed to be able to gather sprouts from it; yet in how few gardens relatively is Chou de Milan grown. Perhaps it wants a new name to make it eagerly sought after. One feature noticeable was that the soil had not been manured, but having been an old pasture with the turf removed, then dug, it had produced these capital plants. Do we really not often create fungoid diseases in Brassica by giving them too much manure?—A. D.

— **DOUBLE PRIMROSES.**—The double Primroses are deservedly favourites, and whenever seen usually attract much admiration. Those most frequently seen are the double white and the double lilac. These are both of vigorous growth, and in this respect compare favourably with some of the others. There are at least two forms of the white. There are also two or three yellows, one being deeper in colour, but less free in growth than the double sulphur. Purple, blush, and several other shades are now represented. The worst fault the double Primroses have in the garden is that they are so liable to be lost from drought or severe frost. They are hardy, but are often lifted partly out of the ground by frost, and if not attended to become lost. They suffer much in dry weather, and it is common enough after a dry season to see that some of the southern growers are unable to offer plants of some of the scarcer forms. They thrive splendidly during summer in a frame placed on a shady border, the glass being shaded with summer cloud or other material. The frame should not be close, and the plants ought to be watered regularly with a fine rose. This will keep down green fly, to which they are subject if grown in a confined atmosphere. Annual division and replanting are almost necessary for these Primroses when large plants are grown.—S. ARNOTT.

— **TOP-DRESSING MINT.**—May I recommend those who top-dress Mint to make a new bed every year in April from cuttings made from the tops inserted about 1 foot by 9 inches apart? When the time comes for boxing roots for forcing they will be delighted with the plants so treated. The above is the practice of most market growers, who, I find, can give us gardeners in private places many wrinkles.—JAS. HAMILTON *Burton-on-Trent*.

— **MARCH WEATHER AT DRIFFIELD.**—Mean temperature at 9 A.M. (corrected), 39.3°. Wet bulb, 37.49°. Mean maximum, 45.93°; mean minimum, 32.96°. Highest, 57.8° on the 18th; lowest, 26.0° on the 15th. Mean of maxima and minima, 39.45°. Mean radiation temperature on the grass, 29.27°; lowest, 21.5° on the 21st. Rainfall, 2.07 inches. Number of rainy days, eighteen; greatest amount on one day, 0.46 inch on the 26th.—W. E. LOVELL, *York Road, Driffeld*.

— **SUSSEX RAINFALL.**—The total rainfall at Stonehurst, Ardingley, for March was 1.29 inch, being 0.79 below the average. The heaviest fall was 0.38 inch on the 3rd. Rain or snow fell on eleven days. Total fall for the quarter 3.45 inches, which is 3.21 inches below the average. The maximum temperature was 53° on the 22nd, and the minimum 27° on the 13th and 25th. Mean maximum, 46.16°; mean minimum, 33.19°; mean temperature, 39.67°—1.19° below the average. The storm of the 25th and 26th was severely felt here, snow falling continuously both days, with strong N.E. wind. Maximum temperature, 35° and 36° respectively, falling to 27° on the former.—R. I.

— **MARCH WEATHER AT HODSOCK PRIORY.**—Mean temperature, 39.9°. Maximum in the screen, 61° on the 18th; minimum in the screen, 20.2° on the 7th. Minimum on the grass, 11.8° on the 7th. Frosts in the shade, seventeen; on the grass, twenty-four. Sunshine, seventy-nine hours, or 22 per cent. of the possible duration; twenty-seven hours below the average. Rainfall, 1.49 inch; below the average, 0.16. Rain fell on sixteen days. Maximum fall, 0.33 inch on the 26th. Rainfall since January 1st, 2.62 inches; 2.49 inches below the average. A rather cold month. White frosts at the commencement, and snow squalls near the end. Vegetation made little progress.—J. MALLENDER, *Workshop*.

— **ARREARS IN RAINFALL.**—Mr. T. P. Newman, Hazelhurst, Haslemere, directs attention, through the “Surrey Times,” to the serious outlook for the summer owing to the very little rainfall that we have had for months. The statistics which Mr. Newman quotes are significant. During the first three months of this year only 4.08 inches of rain were registered, as compared with 13.45 inches in the corresponding period of 1897. Moreover, the closing months of last year were almost equally dry. The seven months from September, 1897, to March, 1898, inclusive, produced 14.04 inches of rain against 34.68 inches in the same period of 1896-7. It is noteworthy that the winter of 1896-7 produced enough rain for a whole year, whereas this last winter has only produced about one-third of that quantity in the beautiful district of Surrey, where the amounts were carefully registered.

— **THE WEATHER LAST MONTH.**—March was much colder than January, and snow fell on several occasions, but melted as it came. The wind was in a westerly direction eighteen days. Total rainfall 1.46 inch, which fell on eighteen days, and is 0.10 inch below the average for the month. The greatest daily fall was 0.42 inch on the 26th. Barometer (corrected and reduced), highest reading 30.293 inches on the 10th at 9 P.M.; lowest, 29.426 inches on the 28th at 9 A.M. Thermometers: highest in the shade 61° on the 18th; lowest, 22° on the 10th; mean of daily maxima, 46.09°; mean of daily minima, 31.61°; mean temperature of the month, 38.85°; lowest on the grass, 16° on the 7th and 10th; highest in the sun, 118° on the 18th. Mean temperature of the earth 3 feet deep, 40.38°. Total sunshine, 107 hours 50 minutes. There were four sunless days.—W. H. DIVERS, *Belvoir, Grantham*.

— **WEATHER AT DOWLAIS.**—Observations here for the past month show a total rainfall (including snow), 1.69 inch. Snow alone, 0.62; which fell on six days. Rain and snow on three days. Rain alone on six days. Greatest rainfall, 0.28 on the 19th; greatest snowfall, 0.28 on the 6th. Mean maximum temperature, 47°; highest reading, 63° on the 21st. Mean minimum, 26.9°; lowest reading, 18° on the 6th. Below freezing point on twenty-seven nights. There were nine sunless days. The wind was in the N. and N.W. on fifteen days, and in the S.W. on nine days. A terrible gale was raging here from the 24th to the 27th inclusive, with blinding snowstorms on the 24th and 26th. On the 3rd we had a fair sample of weather, starting first thing with about three hours' sunshine; heavy clouds came up from the N.W., a very heavy hail storm, with a slight fall of snow, accompanied by thunder and lightning, and finishing with 9° of frost.—WM. MABBOTT.

— **BECKENHAM HORTICULTURAL SOCIETY.**—The members of the Beckenham Horticultural Society have during the last three weeks been enjoying a course of lectures on "Insects Injurious to Garden Crops," given by Mr. P. Hedworth Foulkes, B.Sc., Lecturer on Agricultural Entomology at the University Extension College, Reading. Mr. Foulkes treated upon the various forms of insect pests and their differing modes of attacking the plants, and the most approved methods both of prevention and cure. The lectures were rendered more interesting by the limelight pictures with which they were illustrated. At the last meeting an extraordinary cluster of fine Mushrooms was exhibited by Mr. Mark Webster, gardener to Mr. E. G. Preston of Kelsey Park.

— **RHODANTHES IN POTS.**—Rhodanthes are amongst the prettiest of everlasting flowers, and when grown in pots they make charming decorative plants. Seeds may be sown now in pans or boxes, and when the seedlings are large enough for removal they should be pricked off in 5-inch pots, placing about half a dozen in each. If grown close to the glass in a cool greenhouse they will be sturdy in habit, and when their graceful flowers open the plants are useful for conservatory and room decoration. If cut when ripened and hung up in bunches they will be suitable for decorative purposes in the winter, when flowers are scarce. The seeds of Rhodanthes are usually sold in varieties, the most useful being *R. maculata*, yellow and crimson; *R. alba*, white; and *R. Manglesi*, rose and yellow.—G.

— **PRESERVATION OF FARMYARD MANURE.**—The chemist to the Canadian Agricultural Department has recently completed an experiment in the preservation of farmyard manure which is of interest to farmers. A lot of manure, composed of equal quantities of horse and cow manure, was kept in a partially closed shed for a year. In the first instance it weighed 8000 lbs., and at the end of the year only 2659 lbs. The reduced bulk was much richer in the elements of fertility than the fresh manure, as it well might be, considering that there was a loss of two-thirds of the original bulk. But, although the percentages of nitrogen, phosphoric acid, and potash were greater in the rotten than in the fresh manure, the total quantities were much less. The 8000 lbs. of fresh manure contained 41.6 lbs. of nitrogen, 24.8 lbs. of phosphoric acid, and 60.8 lbs. of potash; whereas the 2659 lbs. of rotten manure a year later contained only 23.6 lbs. of nitrogen, 19.5 lbs. of phosphoric acid, and 39.8 lbs. of potash. The above figures give some idea of what happens when farmers keep manure in dunghills in the open for a long time, where naturally the loss is much more rapid.

— **DEEP SOIL IN GARDENING.**—A wise gardener, who was very successful with his gardens, occupied an acre of ground. But when conversing about his garden he used to inform questioners that he cultivated two acres. This was to his newer friends. But this he did to explain that, instead of digging up the ground some 5 or 6 inches deep, as most cultivators do, he stirred it up to a foot or more—having one of his acres beneath the other. This piece of wisdom is, however, not generally perceived. Double the crops can certainly be obtained from ground loosened in this manner. But this is not understood by the ordinary cultivator. Those who are engaged in the culture of Beet especially know that land is always doubled in value when sub-soiled—that is to say, when the under surface is deeply loosened. It is now well understood that a pulverised soil will hold air and moisture, so necessary to successful culture, to a much greater extent than earth that is packed solid, so that air and moisture cannot be retained. In the drier weather plants will not grow and flourish when under ordinary shallow culture. The plants struggle along and appear tired of life. So says "Meehan's Monthly," and it is quite true.

— **CLIVIAS AT CHELSEA.**—These stately plants, with their handsome strap-like leaves and imposing heads of orange-coloured flowers, are becoming more popular every year. This is as it should be, for they are undoubtedly valuable additions to any collection of plants, as they can be used for various purposes, and are not quick to resent a little neglectful treatment. For the conservatory during the spring they are extremely valuable, especially when the plants have grown to considerable size, while for suitable position indoors they are exceedingly useful. In either case the flowers last a very long time in good condition, and of course the deep green foliage is always ornamental. In one of the many houses flanking the long walk in the Royal Exotic Nursery, Messrs. J. Veitch & Sons have a representative collection of the best varieties, and they make a very handsome display. The plants are in the rudest health, and the immense heads of flowers rising from the deep green leaves are imposing and attractive. Visitors to see the *Amaryllis* should spare a few moments to walk through the *Clivia* house.—H.

— **WIND-FERTILISED FLOWERS.**—Wind-fertilised flowers, it may be noticed, always produce large quantities of pollen, as, for instance, the Hazel, the Willow, and nearly all Grasses.—E.

— **ANEMONE RANUNCULOIDES.**—Lovers of wild flowers have for several springs past been gladdened by the sight of a fair number of plants of the yellow Wood Anemone, *A. ranunculoides*, flourishing in the Embankment Gardens between Waterloo and Charing Cross bridges. They were growing around several of the flower beds, and had most likely been brought thither in the turf used for edging, though so attractive were they that one was tempted to imagine they had been put in purposely, and to thank the authorities for this embellishment to the garden.—("Times.")

— **PERILLA NANKINENSIS.**—Where coloured foliage is required for giving effect among bedding plants or forming contrasts, this half-hardy annual is very suitable for the purpose. *Perilla nankinensis* is very accommodating, and will thrive in almost any position. A rich soil is not desirable, as it is liable to grow very robust, and the purple colouring of the foliage is not nearly so deep. If mixed with flowering plants in beds or borders, and it grows too tall, the tops may be cut off to the level of the surrounding plants. Breaks will soon be made afresh, the colour of which will be very bright. Seeds should be sown in boxes or frame, and the seedlings pricked off in a nursery bed prior to the final transplanting.—H. H.

— **THE "CACTUS JOURNAL."**—We have received the first and second numbers of a new publication entitled "The Cactus Journal," and must congratulate the publishers on the excellent, general appearance, the type being clear and good and the illustrations admirably executed. We regret to observe, however, that the errors in spelling are very numerous, and it will be a matter for regret if the value of the journal should be marred by faulty editing. For example, there are at least half a score of errors in one column, mostly due to the use of capital letters where small ones are correct according to the best authorities. We wish the promoters every success, and hope there are sufficient Cacti growers to support a monthly sixpenny journal. The publisher is Mr. E. W. Allen, 4, Ave Maria Lane, Paternoster Row, London.

— **"THE USE OF THE HOE."**—All teachers of gardening, whether practical or theoretical, are agreed as to the flat hoe being one of the most useful implements in the garden. Stir the surface soil, is the advice frequently given, and it is too good to become hackneyed. Soon the various crops will be showing themselves in the garden, and spring and summer sunshine, following rain, will cake and harden the surface. This will crack, and the moisture that it is advisable to conserve will escape. To hoe ground, except weeds are growing, might strike a novice as being superfluous labour; but gardeners know better, and to assist the maturity of plants there is nothing better than frequently and thoroughly stirring the surface soil with the hoe. More particularly does this apply to stiff clayey soil, the surface of which bakes exceedingly during drought.—H.

— **PROPOSED PARK FOR LEE.**—The Parks and Open Spaces Committee of the London County Council at a recent meeting reported that they had had brought to their notice by a deputation of residents in the district of Lee an offer made by the Earl of Northbrook and Viscount Baring to present to the public, in commemoration of the Diamond Jubilee of her Majesty the Queen, a piece of land nearly 7 acres in extent in Bromley Road, Lee, for the purpose of a recreation ground. The only conditions attached to the gift were that the ground should be taken over by the Council and laid out and properly maintained by it as a recreation ground, and that the costs of Lord Northbrook's solicitor and surveyor should be borne by the Council. Building operations were going on in the district, and there was a Board School close by. In the circumstances they did not hesitate to suggest that the Council should undertake the charge of the land on behalf of the public. It was estimated that the value of the land to be presented to the Council was £4125, and that the solicitor's and surveyor's charges would therefore be about 40 guineas and 25 guineas respectively. There might, however, be some other slight expense, and they therefore asked for a vote of £100 in order to cover all possible outgoings. They estimated the cost of laying out the land, including fencing, seats, and watch box, at £1000, and the annual cost for maintenance at £200. They recommended "That the Council do approve the estimate submitted by the Finance Committee, and do agree to take charge of and maintain as a recreation ground the piece of land at Bromley Road, Lee, offered by Lord Northbrook and Lord Baring, and do undertake to pay the costs of Lord Northbrook's solicitor and surveyor in connection with the matter; that it be referred to the solicitor to take all steps necessary to complete the matter."

CHRYSANTHEMUM G. J. WARREN.

I NOTICE, on page 308, that some doubt has been expressed as to this variety proving satisfactory. Having seen reports on its first appearance in the *Journal of Horticulture* at the end of 1896, I ordered one plant, and have great pleasure in stating that it succeeded beyond my expectations, considering it was the first year of distribution. My plant produced three good flowers, which were exhibited in the famous Jubilee competition at Edinburgh, and one of them was fit to rank in any stand of Chrysanthemums that I have yet seen. Doubtless these flowers were seen at Edinburgh by many Chrysanthemum growers. I have every confidence in the variety, and am growing twelve plants for exhibition blooms this season, which is a large number considering the small amount of glass available here for Chrysanthemums, and there is only one other variety—Madame Carnot—which is similarly favoured by me. The colour of G. J. Warren is best described as canary yellow, and in habit of growth it is the exact counterpart of its parent. Both Mr. Warren, the raiser, and Mr. Wells, the distributor, are to be congratulated on this splendid acquisition which they have given us.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham.*

THE "CARNOT" MYSTERY.

I QUITE agree with Mr. Haggart (page 285) that some elucidation of this subject is desirable in the interest of intending cultivators, and especially exhibitors of Chrysanthemums. I have never experienced the misfortune of disqualification, like Mr. Haggart, but have many times been compelled to write the distasteful word on the entry card, and often with regret, as I have much sympathy with young showmen who have been misled into a position of false security.

In the majority of instances the exhibitor has had to pay the penalty which he unfortunately incurred through following too closely the classification of certain varieties by Chrysanthemum vendors. Many times I have gleaned this as the cause when in conversation with the victimised exhibitor, who almost invariably remarks, "I thought this was quite right, Mr. So-and-so classes it as such and such." Very often I have replied, "What a pity you did not consult the N.C.S. catalogue, which is the generally acknowledged guide in cases of nomenclature. This is an authority, whereas Mr. So-and-so's catalogue is but the opinion of an individual." Too frequently, I am sorry to say, the reply comes, "Why, I did not know there was a N.C.S. catalogue!" The ignorance of the existence of such a guide has surprised me many times, especially knowing as I do that Chrysanthemum exhibitors as a rule read attentively. This is, however, somewhat of a digression, and I return to the "mystery."

It is an unfortunate circumstance when varieties which are identical, or as nearly so as possible, receive distinct names. For this there can only be one reason, which is all too obvious. Upon matters of nomenclature in Chrysanthemums I have fixed opinions, as several of my friends know, though some of my views may seem to them a little pedantic. In the long run I am convinced they will not be found so, but, on the contrary, point in a severely practical direction.

One of my contentions is that a new variety, be it a sport or otherwise, should retain the name with which it was originally invested, and any sport of a similar nature appearing subsequently in any other part of the country, or subsequently exhibited, should receive no other than the same original name. This would prevent confusion, wasteful expenditure, and disappointment. If this is not a practical view I should like to know what is. The sport from Prince Alfred, named Lord Wolseley, occurred in two distinct places the same year, but there was only one distinct variety, not two, and the only rightful name for both was that first given—Lord Wolseley.

In the question raised by Mr. Haggart, in my opinion a long stretch of imagination is required to distinguish the difference between G. J. Warren and Yellow Madame Carnot. Mr. Wells procured and exhibited G. J. Warren in 1896. To be accurate, it sported in the gardens at Balcombe Place, near Brighton, and received its name in compliment to the gardener there.

I have had ample opportunity of comparing G. J. Warren and its co-sport Mrs. W. Mease; having seen large and small blooms of both under various circumstances, I have no hesitation whatever in saying they are quite distinct. At the end of November last I had examples of both before me every day, for at least a fortnight, for the express purpose of notifying any change of colour, should there be any, while the blooms were passing through the various stages of development and decay. As is customary with all flowers, the colour in both faded somewhat, but it was proportionate.

G. J. Warren is yellow in colour. Many catalogues describe it as canary yellow. I am not sure this is the right description, as there are both pale and deep shades of colour in canaries. I am more inclined to say that the colour is yellow, inclining to golden yellow.

Mrs. W. Mease is a pale or soft shade of primrose. The bloom of this variety that secured for Mrs. Mease the premier distinction in the Japanese section at the N.C.S. November exhibition, was a distinctly typical one. Some of the best coloured blooms of G. J. Warren that

I have come across were staged at the Edinburgh Show last November. That they were thoroughly distinct from Mrs. Mease there cannot be one single doubt.

I fail to see any difference between G. J. Warren and Yellow Carnot.

This family, like many other types of Chrysanthemums, both Japanese and incurved, bids fair to become a large one. The latest addition to the "Carnot" group is a pink form, which I am hoping to test during the current season. If this addition to a deservedly popular family possesses, as I hear it does, all the charming characteristics of its parent, it will be a distinct gain to the Chrysanthemum world, as it is most difficult to conceive a more elegant type of a Japanese Chrysanthemum than the original Madame Carnot, sent out by that enterprising and successful raiser, Mons. Calvat.—EDWIN MOLYNEUX.

[Our experienced correspondent's views on nomenclature are indubitably sound. They are in accord with the recognised practice of botanists all over the world. The first name of a plant, unless it is proved to be scientifically wrong, has priority over all others. If this principle were formally ratified by the N.C.S., good service would be done to the great community of Chrysanthemum purchasers and exhibitors. At present the weight of evidence is decidedly in favour of the distinctness of G. J. Warren and Mrs. Mease, but not of the distinctness of G. J. Warren and Yellow Madame Carnot. It may be expected that the exact origin of the last named will be made clear by persons who are intimately acquainted with the facts of the case. Records of the origin of sports are always interesting, and may be important.]

TROPÆOLUM JARRATTI IN BASKETS.

AMONG exquisite plants which springtime brings to perfection in our cooler structures for floral display is this lovely little Tropæolum. It should be grown by every plant lover, and those who do not yet know it, although it is an old introduction, should inquire of their friends to be allowed to see its charms during the present month, when it is at its best. I do not think I venture too far in my praise of this plant in anticipating that everyone who sees it for the first time in its best condition will desire to have it in his greenhouse next season.

Growing this plant is simplicity itself. The fine tendrils are the only difficulty, as they grow rapidly, and must in their progress be kept under control and fixed as they extend. The dry tubers, of the size of a Chestnut, should be placed singly in large 60's early in August in peat and silver sand as soon as the fragile fresh tendril becomes observable in the flowering pot of the previous season, where it has been left quite dry from finishing flowering in the spring. The tubers should be barely covered, and the tendril left quite exposed.

To any ordinary wire trellis of balloon or other shape I have given preference by transferring the plants from their quarters in 60's to wire baskets suspended 7 feet high across the passage round the greenhouse. The baskets are lined with moss, supplying as much soil as the former can fairly take. The object is thus gained, after training the lead to the lowest point of the basket, to be able to wind it round its curving sides, and gradually round its widest circumference.

Watering must be done sparingly until growth becomes relatively rampant. The amount of flowering on the greater part of the entire length of the tendrils depends on a very light and airy position, where they represent a dream of beauty for about a month.—H. H. R., *Forest Hill.*

ANEMONES AND RANUNCULUSES.

THESE two flowers, which have both been great favourites in our gardens for ages past, belong to the same natural order—Ranunculaceæ, of which the common yellow Crowfoot of our fields is the type and representative. The garden Ranunculus came originally from the milder climates of lands bordering on the Mediterranean, but has now been cultivated in this country for the last three centuries. Gerard reared them, as he tells us, in 1594; Parkinson in 1629 enumerates eight varieties; and Ray, forty years later on, increased the list to twenty-five. It was not, however, till the middle of the last century that the Ranunculus, like some other flowers, reached the height of popularity, and became in great demand. Then numbers of new sorts were reared, and florists, we are told, became absolute idolators of the beauty and variety of their colouring.

The Anemone is a native of the same parts as the Ranunculus, and was introduced to England from Italy towards the close of the sixteenth century. Like many other plants in its wild state, it has its flowers single; but the corolla can be multiplied almost indefinitely by the conversion of its stamens and pistils into petals under judicious culture. The Anemone takes its name from a Greek word signifying wind flower, an appellation actually bestowed upon it by our forefathers, from the circumstance of its growing naturally in open plains or exposed situations, where its feathery grains produce a singular shining appearance when waved by the breeze.

When first introduced there were only a few species, but since then Art has so increased the varieties of this light and graceful favourite, that florists have long since ceased to attempt to distinguish them by individual names. The colours, both of the Ranunculus and the Anemone, are clear, rich, and brilliant, partaking of almost every hue, and are either in single uniform tints, or mottled with stripes and patches.—WM. NORMAN BROWN.

LAWNS AND ALLIED SUBJECTS.

(Continued from page 298.)

THE TENNIS LAWN.

THE popular pastime of lawn tennis being now regarded as an institution in gardens, it holds, in relation to our subject, a prominent place. There are, indeed, few places where the tennis ground is not in evidence; too much so, one may say, by reason of the exposed position it often occupies. In many cases, owing to limitation of the grounds, this is, of course, unavoidable; but many there are in which this most important consideration appears to have been overlooked, hence what is considered an ideal position (fig. 64), illustrates the meaning, whilst the points in its favour may briefly claim attention.

In the first place it must be stated that in considering the limited area with which we are dealing, any question of primarily selecting

billiard table. *Apropos* of this it may be repeated that a dead level is seldom desirable, even with a tennis ground, but in this case it will be remarked that the made-up portion sank sufficiently to give the slight fall desirable, such sinkage being regular, unnoticeable, and inappreciable so far as the playing was concerned, but sufficient to obviate any lodgment of water. The space actually required for marking out the tennis court is 78 by 36 feet; to this a margin of 10 feet at each end is advisable, with 6 feet on each side, or, at a rough calculation, the prepared ground will be 100 by 50 feet.

It is important that the tennis ground, whatever margin may be allowed over actual requirements, should be correctly rectangular, thus facilitating the initial marking out and necessary measuring each season. Markers, when placed at each corner and at each end of every white line, will save considerable labour during wet weather, when the lines are generally obliterated. Special iron pins with flat square heads are sold for the purpose; but I prefer those made by a country blacksmith as being stronger, the former being liable to lose their heads.

FIG. 64.—THE TENNIS GROUND—AN IDEAL POSITION.

References.—1, Portion of Park; 2, Pleasure Grounds and Seats under Trees; 3, Steps with Vases; 4, Tennis Ground on Sloping Lawn.

the most level ground obtainable for the scene of operations need not be entertained. A little explanation of the view given will, however, be the best interpretation. Proximity to the residence is the first point in its favour, whilst the privacy afforded by the screen of foliage, which not only almost excludes the building from view but the carriage approach to it, so that visitors calling avoid that rather awkward *contretemps* of seeing the family when "not at home." Ample shelter on a hot day is also afforded to on-lookers by seats being freely disposed under some fine trees in the foreground, as well as to players from a passing shower, whilst the view commanded from this sequestered nook, embracing a broad sweep of the park, is, to say the least, satisfying.

As will be noted, the position is on rather sharply falling ground towards the park railing as well as longitudinally. The fall lengthwise of that portion comprising the tennis ground being previous to levelling 4 feet. This necessitated an excavation of 2 feet at the corner where the grass steps are formed, and the raising of the lower end by 2 feet with the soil removed. The hard pan existing at the excavated end was well broken up, and special precaution taken that the made-up portion at the lower end was well consolidated by ramming and tramping as the work proceeded. Previous to turfing a liberal dressing with the compost previously prescribed was given to it, and when completed the new tennis ground was as level as a

Experience teaches the value of observing what may be considered as trifles; hence such details are thought to be worthy of inclusion here. "Please have the tennis ground marked at once," is an order not infrequently given, and a rather nice operation which few workmen accomplish as I, at least, like to see it; so, with the assistance of a boy, generally do it myself. Good whiting is the only satisfactory medium for marking, and this, mixed with water to the consistency of thick cream, is easily applied with one or other of the machines generally used. Mowing the tennis lawn when in frequent use must enter into our calculation. In this case, the best method is to make a daily operation of it; it is then always ready.

In the place from which the illustration is taken the rule is for one of the pleasure-ground men to run his hand machine—one of the light running 16-inch mowers, with the grass-box attached—over it every morning before breakfast, weather permitting; and it is preferred to keep the one machine specially for this purpose. A daily run with the roller over new-made grounds is advisable. "What a lot of pains you take with your tennis ground," a neighbour remarked. True, it was admitted; but the "lot of pains" experience proves to give least trouble in the long run, with satisfaction to all concerned.—SYLVA.

(To be concluded.)

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—"VICTORIAN ERA FUND."

READERS will doubtless remember that this fund was established last year to commemorate the completion of the sixtieth year of her Majesty's beneficent reign. They will also recollect that its object is to temporarily assist unsuccessful candidates whilst awaiting election, who have been (or their husbands) subscribers to, or life members of, the Institution. The total amount received up to December 31st last has been invested, and the Committee are glad to be able to announce that the income derivable therefrom this year enables them to distribute the sum of £106 10s., the first half of which was sent on April 1st last to eighteen unsuccessful candidates as follows, and has been divided at the rate of 15s. for each year they (or their husbands) had subscribed.

	Years	Self or Husband	Amount sent
	subscribed.	April 1st, 1898.	
Bryan, Andrew	13	£4 17 6	
Nixon, Francis	13	4 17 6	
Plevy, James	12	4 10 0	
Staples, George	11	4 2 6	
Wood, Caroline	11	4 2 6	
Gibbons, John	10	3 15 0	
Watt, James	10	3 15 0	
Hackwell, Elizabeth	9	3 7 6	
Wills, George	9	3 7 6	
Barnfield, Alfred	8	3 0 0	
Hatch, Annie	8	3 0 0	
Mitchell, Lucy	7	2 12 6	
Shearn, Joseph	7	2 12 6	
Lee, Alexander	5	1 17 6	
Evans, Thomas	4	1 10 0	
Gould, William	2	0 15 0	
Thomas, William	2	0 15 0	
Woodward, Emma	1	0 7 6	

From the above it will be seen that the aggregate number of years of subscription is 142, which, at 15s. each year, gives a total of £106 10s., the first instalment of which, as already stated, was sent on April 1st last, and the remainder will be sent on October 1st next. The Committee are very anxious to bring up the total amount of this fund to £5000, to do which they require a sum of £925, and I should like to draw attention to the generous offer made by N. N. Sherwood, Esq. (Trustee), to contribute £50, provided the amount required be raised, in response to which the following gentlemen have each kindly promised a similar sum. Arthur W. Sutton, Esq., Reading; Leonard Sutton, Esq., Reading; Harry J. Veitch, Esq., Treasurer, and several smaller contributions have been already received. The Committee sincerely hopes before the close of the year to be able to announce that the balance necessary to make up the £5000 has been received. It is trusted therefore that every well-wisher of the Institution will note that the "Victorian Era Fund" is still open, and that donations to it will be most gratefully received. The Committee also desire again to emphasise the notice which has already appeared in your columns, and elsewhere, that this fund is intended for the benefit of those only who have subscribed to the Institution.—G. J. INGRAM, *Secretary*.

FRENCH AND AFRICAN MARIGOLDS.

THESE may be accepted as illustrating the aphorism of Longfellow—"Things are not what they seem"—because they are neither French nor African, nor are they yet Marigolds. An account of both plants is to be found in "Stirpium Historiæ" (1582), and from this we are able, with a little help from other quarters, to arrive at a definite conclusion as to why these inappropriate designations came to be applied to them. Both were termed africanus because it was believed they grew wild in many places in Africa, and it was current they had been brought thence by Charles V. of Spain on his return from Tunis in 1535-36. Another account had it that they were brought by Germans from Peru. Some also discovered in them the Petilium Flos of Pliny, and the French, as a matter of fact, accepted Tagetes patula as identical. In England it was called French Marigold because, as an old writer affirms, "the French taught us how to cultivate this flower." From the "Scots Gardner" (1683) we discover from its absence that the French Marigold was unknown at least to the Scottish horticultural literature of that period.

Miller mentions eleven varieties of the African Marigold as being in cultivation about the middle of last century. Of these the varieties which interest us most are the "double" forms, or those with flat florets, and the "fistulous," or those with quilled petals. This predilection for quilled Africans has continued to the present day, with the result that a flat-petalled flower shown against a quilled has, with not a few judges, only a slight chance of obtaining a prize. An essential point in the culture of this plant for exhibition, after securing a first-class strain, is to grow one stem only to each plant, and rigorously to remove all side growths, in order that the whole strength of the stem may be directed to the one flower which crowns its summit. A too rich soil conduces to coarseness as well as size, and it is better to depend on dressings applied as required than to overload the soil with manure previous to planting. The Orange and the Lemon are the forms now esteemed most highly for exhibition.

From the above the selection and treatment of the French Marigold widely differs. It is, moreover, a more useful plant, the very dwarf single

and double varieties being of much service for a certain class of bedding. The dwarf forms, however, are by no means new, for we find them named over a century ago. Hill says, "Choose the best striped of the French Marigold, and the largest and most quilled of the African," and such flowers secure the best prizes at the present day.

It is a fact not without interest that one plant of French Marigold, grown in well-worked soil, but not too rich, and allowed space for free development, will produce continuously blooms single, double yellow, double red, and striped of the highest quality. For this reason only a few plants are required for the production of exhibition blooms.

It is a mistake to sow either of these Marigolds earlier than April; from beginning to end, according to locality, being a suitable time. The aim of the cultivator should be to grow the plants without check, and this is effected with the greatest certainty when the seedlings appear sufficiently late in spring to secure a share of genial weather from their earliest appearing.—R. P. BROTHERSTON.

NOTES ON ALPINE FLOWERS.

(Continued from page 262.)

PRIMULA MARGINATA.

SOME of the choicest of our Alpine flowers are to be found among the Primulaceæ, and in that beautiful family what are known as the Primula species hold a prominent place. Some of these are comparatively difficult to grow, but others are easily cultivated in the rock garden. Included among the plants passing under the name of "Primula species" are several hybrids and varieties, more or less marked, of true species. The subject of this note—Primula marginata of Curtis—has some variation in shade of colour and in size of flower, but all the varieties resemble each other in every material point.

In Mr. J. G. Baker's synopsis of the European species of Primula, read at the Primula Conference of the Royal Horticultural Society in 1886, P. marginata was included in Group III.—Auriculastra. It comes from the Alps of Dauphiné and Piedmont. It is easily recognised by the white margins round the toothed silver-grey leaves, which make the plant very attractive, even after the flowering period. The Margined Primrose grows from 2 to 6 inches high, and thrives best in a partially shaded position in a light soil not too dry. The colour is called by Mr. Baker "lilac," and by others "violet-rose." The latter is, the writer thinks, nearer the colouring as grown outdoors and without covering. This colour, as has been mentioned, varies, and among the best forms are Dr. Stuart's variety and major. The most distinct in colour is known as P. marginata var. cœrulea, and is of a pretty bluish tint not frequently met with in the genus except among the new blue Primroses now attracting so much attention. This Primula can be confidently recommended, and requires less care than many others. The Margined Primrose is increased by means of division.

AUBRIETIA TAURICOLA.

One might devote more space than is at present at command to expatiate upon the beauties of the Aubrietias, and their uses in the rock garden. In spring their purple, violet, or rose flowers are of striking effect, depending from the ledges of the rocks or draping a large stone with a sheet of brilliant flowers. A. tauricola is a beautiful little variety of more compact habit than many of the varieties of A. deltoidea, to which it seems to belong. This renders it suitable for association with the more select alpine. The flowers are also of a good colour and size, so that the plant which passes under the name of A. tauricola is one deserving of attention from Alpine growers. It may be that it is the same as the Aubrietia grown at Kew as A. deltoidea var. taurica, but the writer has not at present an opportunity of comparing the plants.

ALYSSUM MONTANUM.

Mountain Madwort is the alliterative English name of this very pleasing little Alyssum. It comes from the Alps and Pyrenees, and has been in cultivation for many years. Like a large number of the perennial Madworts it has yellow flowers. These are in simple racemes, and are only a little above the spreading tuft formed by the stems and leaves. The leaves are rough and of a dull greyish green. Some growers appear to have a difficulty in keeping Alyssum montanum for any great length of time. After some winters it has looked a little unhealthy in this garden, but has always recovered. It is grown in light soil in the upper pockets of a low rockery, but is kept well supplied with water in continued dry weather. The Mountain Madwort is easily raised from seeds, and may also be increased by means of cuttings.

PENTSTEMON CONFERTUS.

This is Douglas's name for a very dwarf and hardy little "blue" Pentstemon, grown also under the names of confertiflorus and procerus. Under the name of P. confertiflorus seeds are offered, and plants may also be seen catalogued as P. procerus. Its English name is the Whorled Pentstemon. A very pretty little plant it is, of dwarf habit, only growing from 7 or 8 to 14 inches high, and producing many racemes of blue purple-veined flowers. The leaves are lance shaped, and this Pentstemon is a very desirable alpine, and is quite hardy in the rock garden or border in almost any soil. It is increased by division as well as by seeds.—ALPINUS.

(To be continued.)

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—APRIL 12TH.

THE exhibition on Tuesday was one of the finest that has been seen in the Drill Hall at this season of the year. Almost the whole of the available space was occupied with floral exhibits of high quality. Orchids were admirably though not extensively shown, while exhibits for the Fruit Committee were very few. Narcissi were staged in superb condition.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); Rev. W. Wilks, with Messrs. J. H. Veitch, A. F. Barron, T. Fife, J. Willard, G. Norman, G. Reynolds, J. Smith, J. T. Miles, G. Sage, M. Gleeson, W. Bates, F. Q. Lane, C. Herrin, A. Dean, and J. Wright.

Only a few products were placed on the table for examination, but these were distinctly meritorious, and met with prompt recognition.

Mr. J. Miller, Ruxley Lodge, Esher, sent a large box of Mushrooms. They were grown on ridges in the open air, and were remarkably firm and fine. Mr. Miller is an adept in this method of growing the delicious esculent. A cultural commendation was unanimously awarded.

Mr. McLeod sent from Dover House, Roehampton, a box of splendid Brown Turkey Figs, gathered from a trained tree, covering a space 6 by 18 feet, and now carrying 470 fruits, of which these were fair samples, and excellent they were. A cultural commendation was voted unanimously.

Mr. E. Beckett sent from Aldenham House, Elstree, a large basket of Laxton's Royal Sovereign Strawberry. The fruits were very fine, firm, and richly coloured, meriting the cultural commendation which was promptly granted.

A dish of a small well-coloured seedling Apple from Mr. W. W. Bull, Ramsden, Billericay, was placed on the table—fruits small, round, and coloured. They were somewhat shrivelled. The Committee desired to see others next year in a firmer condition.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, O. Thomas, C. T. Druery, R. Dean, J. H. Fitt, G. Stevens, W. Howe, J. F. McLeod, T. Peed, C. J. Salter, J. W. Barr, J. D. Pawle, H. J. Jones, C. Jeffries, C. E. Shea, D. B. Crane, E. Beckett, H. J. Cutbush, G. Paul, J. Fraser (Kew), E. T. Cook, H. Turner, and E. Mawley.

The large group of Cinerarias arranged by Messrs. J. Carter & Co., Holborn, was very effective. The plants were of medium height, many of the flowers being of good form and rich in colour. They were interspersed with Maidenhair Ferns, and backed by small Palms. Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, staged a small collection of Alpines, amongst which were noted many charming and interesting plants. Messrs. J. Hill & Son, Lower Edmonton, were represented by a handsome exhibit of Ferns, comprising many species and varieties, all in excellent health. Well grown and flowered plants of *Azalea indica* were shown by Mr. W. Kemp, Barnes. The colours were very bright. Along the front of the table were fine pots of *Lily of the Valley*. Messrs. W. Paul and Son, Waltham Cross, exhibited in their customary admirable condition *Camellias*, both in a cut state and plants. The flowers were of fine substance and the colours rich. Prominent amongst the varieties were *L'Insubria*, *Princess Charlotte*, *The Duchess*, *Beali*, *L'Avenir*, *Cup of Beauty*, *Mathotiana*, *Montironi*, *C. M. Hovey*, and *Beauty of Waltham*. The five boxes of *Maréchal Niel* Roses shown by Mr. J. Walker, Thame, were the most fragrant feature of the show. The flowers were full and of rich colour. Messrs. R. Wallace & Co., Colchester, sent a capital collection of *Erythroniums*, together with *Fritillarias*, *Tulipa Greigi*, *Irises*, and other flowers.

Hybrid *Streptocarpus*, with a few Ferns and Palms, formed the exhibit from Messrs. J. Laing & Sons, Forest Hill. The flowers were particularly conspicuous for size and substance. Mr. W. Rumsey, Joynings Nurseries, Waltham Cross, sent a large number of Roses, comprising many of the best known varieties. These were *Maréchal Niel*, *Niphetos*, *Général Jacqueminot*, *Charles Lefebvre*, *Ethel Brownlow*, *Elise Fugier*, and the charming *Mrs. Rumsey*, with its shapely flowers borne on long stems. Messrs. W. Cutbush & Sons, Highgate, staged well-grown plants of *Deutzia Lemoinei*, *Staphylea colchica*, and dwarf *Laburnums*. Roses in pots from Messrs. Paul & Son, The Old Nurseries, Cheshunt, were attractively beautiful. Some of the best were *Innocente Pirola*, *Caroline Testout*, *Elise Fugier*, *Clara Watson*, *Captain Hayward*, *Mrs. R. G. S. Crawford*, *Madame Hoste*, and *Antoine Rivoire*, with several of the dwarf *Polyantha* varieties. Primulas in extensive variety were shown by P. Purnell, Esq., Streatham Hill. As a rule the plants were well grown, and flowering freely. Messrs. Barr & Sons, Covent Garden, sent a small collection of Hyacinths, in which several of the leading varieties were observed. Mr. Charles Turner sent from the Royal Nurseries, Slough, baskets of *Nepeta glechoma variegata*, an old but very charming plant for the purpose.

One of the most effective exhibits was that staged by Mr. H. B. May, Upper Edmonton. It was composed of grandly grown plants of *Crimson Rambler Rose*, with *Hydrangeas*, Ferns, *Spiræas*, *Acers*, and other plants effectively disposed in a semicircle. Mr. May also sent small plants of *Begonia Gloire de Lorraine*, which is evidently useful for spring as well as winter flowering. Mr. Miller, gardener to Lord Foley, Ruxley Lodge, sent several bunches of fine Violets. Mr. H. Walters, gardener to Lord Gerard, Eastwell Park, Ashford, showed Roses in variety, the flowers of *Maréchal Niel* being particularly good.

On the floor in the centre of the hall Messrs. Sutton & Sons, Reading, had a group of plants of what they call *Cineraria stellata*, which is a selection from *C. cruenta*. The plants were tall, and carrying graceful trusses of many coloured flowers. Almost all the colours found

in the garden varieties were represented. The plants were clothed to the pot with foliage. Messrs. J. Veitch & Sons, Ltd., Chelsea, sent a group of hybrid *Cinerarias* resulting from a cross between *C. cruenta* and garden varieties. Some of the plants were from seeds and others from cuttings, the former being very much freer flowering and of more graceful habit. The colours were well diversified. The same firm sent also *Deutzia Lemoinei*, *Azalea obtusa alba*, *A. carminata splendens*, *Rhododendron racemosum*, and several other plants. Mr. W. Bardney, gardener to Sir Peter Walker, Osmaston Manor, Derby, staged spikes of different varieties of *Clivia miniata*. The flowers were of great size and the colours exceptionally rich. Mr. E. Beckett, gardener to Lord Aldenham, Aldenham House, Elstree, showed a basket of a form of *Deutzia gracilis* with variegated leaves.

NARCISSUS COMMITTEE.—Present: J. Bennett-Poë, Esq. (in the chair); with Miss Willmott, and Messrs. De Graaff, W. Ware, R. Barr, G. H. Engleheart, C. Macmichael, Kingsmill, J. Walker, and Scrase Dickens.

Mr. Miller, gardener to Lord Foley, staged a few Narcissi, including *incomparabilis stella*, *Burbidgei*, *Leedsii*, *Duchess of Brabant*, *princeps*, and *Emperor*. Mr. T. S. Ware sent a collection of Narcissi, comprising many flowers of fine quality, such as *Victoria*, *maximus*, *Glory of Leyden*, *Horsefieldi*, *M. J. Berkley*, *Sir Watkin*, *P. R. Barr*, *Grand Duchess*, *Catherine Spurrell*, *albicans*, and dozens of others. The Narcissi shown by Messrs. J. Veitch & Sons were remarkable for the excellence of the quality. There were grand examples of *princeps*, *Golden Plover*, *Gloria Mundi*, *Barri conspicuus*, *Horsefieldi*, *maximus*, *Captain Nelson*, *Princess Mary*, *Sir Watkin*, *Chieftain*, *Emperor*, *Queen Bess*, *Empress*, *Mary Anderson*, *Glory of Leyden*, *F. W. Burbidge*, *Flora Wilson*, *Mrs. W. T. Ware*, *Beauty*, and others.

Messrs. Barr & Son, Covent Garden, were represented by a superb exhibit of Narcissi. The flowers were of fine size and great substance, the colours being particularly clear and bright. Amongst the many excellent varieties were *obvallaris*, *Barri conspicuus*, *King of the Netherlands*, *Sensation*, *Flora Wilson*, *M. J. Berkley*, *Ellen Barr*, *Mrs. W. Ware*, *P. R. Barr*, *Sharman Crawford*, *Duchess of Westminster*, *Constance*, *Grand Duchess*, *Madame de Graaff*, *Hogarth*, *maximus*, *Backhousei*, *Portia*, *Golden Spur*, *Gloria Mundi*, *King of the Netherlands*, *St. John's Beauty*, *Goliath*, *Minnie Hume*, *Henry Irving*, *Maurice Vilmorin*, *Hume's Giant*, *Princess Mary*, *William Goldring*, *Princess (double)*, *Fred. Moore*, *Katherine Spurrell*, *Wcardale Perfection*, *Beauty*, *John Bain*, *Sir Watkin*, *Victoria*, *Empress*, *C. J. Backhouse*, *Emperor*, and *poeticus ornatus*. This was probably one of the finest groups of Daffodils Messrs. Barr and Son have ever staged.

NARCISSUS COMPETITION.—The Rev. G. H. Engleheart, Andover, secured the premier prize for a collection of Daffodils. His exhibit was comprised of seedlings, many of which were of high quality. J. W. Jones, Esq., Woking, was adjudged the second prize with a very creditable exhibit.

ORCHID COMMITTEE.—Present: S. Courtauld, Esq. (in the chair); with Messrs. J. O'Brien, de B. Crawshay, R. B. White, H. M. Pollett, H. J. Chapman, F. J. Thorne, W. H. Young, W. H. White, W. Cobb, T. W. Bond, H. Ballantine, and F. Mason.

Mr. F. J. Thorne, gardener to Major Joicey, Sunningdale Park, Sunningdale, sent a number of grandly grown plants of *Epidendrum bicornutum* flowering as this Orchid is unfortunately seldom seen. Mr. Thorne sent also a plant of *Dendrobium atro-violaceum*, carrying a splendid spike of flowers. Mr. W. King, gardener to J. Colman, Esq., Gatton Park, Reigate, showed a few Orchids in good condition, the plants being well flowered. Mr. W. H. Young, Orchid grower to Sir F. Wigan, East Sheen, staged a grand spike of *Coelogyne pandurata*. Mr. H. J. Chapman, gardener to R. I. Measures, Esq., Camberwell, exhibited a group of Orchids, comprising *Angræcum modestum*, *Dendrobiums*, *Cattleyas*, *Cymbidiums*, and several others in good health. Mr. J. Bradshaw, The Grange, Southgate, staged *Cattleyas*, *Odontoglossums*, and *Cymbidiums*, in good variety and fine condition.

From Mr. H. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Dorking, came *Eulophiella Peetersiana*, *Cypripedium Olenus* Burford variety, *Odontoglossum nebulosum candidum*, *Dendrobiums crassinode*, *crepidatum*, *micans*, *Epiphronites Veitchi*, *Odontoglossum coronarium* *miniatum* var., *Polystachya Ottoniana*, *Leptotes bicolor* and *Odontoglossum Pescatorci* Prince of Orange. Messrs. J. Veitch & Sons exhibited a bright collection of Orchids, amongst which were *Epidendrams*, *Lælias*, *Dendrobiums*, *Cymbidiums*, a new hybrid *Phalenopsis* named *Stuartiano-Manni*, *Epidendrum elegantulum leucochilum*, and others. Smaller exhibits of Orchids came from Baron Schröder, H. T. Pitt, Esq., A. Warburton, Esq., and many others.

CERTIFICATES AND AWARDS OF MERIT.

Amaryllis Daones (J. Veitch & Sons).—A very distinct variety. The central colour is bright orange red, and each segment has a margin of white (award of merit).

Camellia Mrs. J. Buchanan (W. Paul & Son).—A semi-double variety, of which the flowers are blush, spotted, splashed, and flaked bright scarlet (award of merit).

Camellia Duchess of Teck (W. Paul & Son).—This is a finely shaped double; the colour is rich rose (award of merit).

Camellia Pride of Waltham (W. Paul & Son).—A dwarf-habited variety with silvery-rose flowers. The flowers are large and substantial (award of merit).

Cypripedium Olenus, Burford variety (W. H. White).—A magnificent variety, in every respect superior to the type, which was a hybrid resulting

from a cross between *C. bellatulum* and *C. ciliolare* (first-class certificate).

Dracæna aurca striata (H. Low & Co.).—A broad-leaved handsome form, of which the name tells the colour. It has the appearance of being a vigorous grower (award of merit).

Epidendrum elegantulum leucochilum (J. Veitch & Sons).—A lovely Orchid, of which the sepals and petals are yellow, and the lip pure white (award of merit).

Eulophiella Peetersiana (W. H. White).—This is a superb Orchid. The prevailing colour is deep rose, with a suffusion of purple. The tubular lip has the normal colour on the front lobe, and a white throat with rose veins, and a flush of yellow (first-class certificate).

Narcissus Oriflamme (G. H. Engleheart).—A lovely variety, of which the segments are cream, and the crown very bright orange (award of merit).

Narcissus Homer (G. H. Engleheart).—Probably the finest poeticus that has been shown. The colour is pure white, and the crown glowing crimson (first-class certificate).

Narcissus Lucifer (G. H. Engleheart).—A good incomparabilis. The segments are cream, and the crown orange yellow (award of merit).

Narcissus White Queen (G. H. Engleheart).—A pale Sir Watkin. The segments are glistening cream, and the trumpet pale yellow (first-class certificate).

Narcissus Lady Margaret Boseawen (G. H. Engleheart).—A handsome variety. The segments are white, and the cup pure yellow (first-class certificate).

Narcissus Apricot (Barr & Sons).—The trumpet of this variety is pale yellow, and the segments creamy white (award of merit).

Narcissus Lady Helen Vincent (Barr & Sons).—A grand variety. The immense trumpet is pure yellow, and the broad segments pale canary yellow (award of merit).

Odontoglossum Wilckeanum Pitt's variety (H. T. Pitt).—A superb form of the type. The chocolate patches and spots are superb (first-class certificate).

Odontoglossum crispum Lindeni (A. Warburton).—A small-flowered variety. The large blotches on sepals, petals and lip are chocolate brown (award of merit).

Phalenopsis Schroderæ (H. Low & Co.).—A hybrid resulting from a cross between *P. leucorrhoda* and *P. Portei*. The petals and sepals are white, very delicately flushed, and with a few brownish spots on the lower sepals. The lip is white, with rose and yellow markings (award of merit).

Phalenopsis Stuartiano-Manni (J. Veitch & Sons).—The above name tells the parentage of this hybrid, of which the flowers are intermediate in size between the parents. The ground colour is buff yellow, and the numerous spots dull crimson (award of merit).

MEDALS.—The following medals were awarded:—Floral Committee: Silver-gilt Banksian to Mr. H. B. May; silver Flora to Messrs. W. Paul and Son, W. Rumsey, and Paul & Son; silver Banksian to Mr. J. Walker; and bronze Banksian to Messrs. W. Kemp and H. Walters; and bronze Flora to R. Wallace & Co. and J. Carter & Co. Narcissus Committee: Silver Flora to Messrs. Barr & Son, and a silver Banksian to Messrs. J. Veitch & Sons, Ltd. Orchid Committee: Silver Banksian to Messrs. F. J. Thorne, J. Bradshaw, J. Colman, and J. Veitch & Sons, Ltd.

CHIONODOXA LUCILIÆ AND ITS ALLIES.

I CANNOT but take somewhat of a paternal interest in this beautiful bulb. It is now about seventeen years since Mr. George Maw brought it under the notice of English gardeners, having found it in Asia Minor; and a figure of it appeared in the "Garden." A copy of this I sent to Mr. Edward Whittall, asking him if he knew it, and whether it were procurable. He said, "Yes, in any quantity." Most of the leading nurserymen to whom I communicated this intelligence wished me to order them a quantity, and some 60,000 bulbs were sent over, and I shall never forget my consternation when, on opening the first consignment of some 10,000 bulbs, I found them all rotten, owing to their having been packed in some material which fermented. However, the losses were soon repaired, and the bulbs were distributed.

Some experts said that they believed, when they received their bulbs, that most of them were *Scilla bifolia*, and when in the spring a few of the more forward ones flowered, and one or two appeared first as *Scilla bifolia*, I began to be afraid that the venture was an unsuccessful one. But I had confidence in Mr. Whittall's botanical knowledge, and I was not surprised to find that these were only exceptions, and that the vast majority were really *Chionodoxas*. Some German travellers were soon on the track, and sent over a large number of bulbs, which brought down the price, and it has since been cultivated in every part of the kingdom, and has proved to be one of the most beautiful and easily grown of the spring bulbs.

I planted bulbs in a border about 40 feet in length, and a few years afterwards sowed a number of seeds in the opposite border, and these have flowered every year. The border was originally about 1 foot wide, but so rapidly have the plants increased and spread that it is now double that width, and is rapidly filling up the whole of the space. The time of their flowering is one to me of great pleasure. They came in full flower just prior to the recent terrible storm of wind and snow, and when they were bending beneath 4 inches of snow I thought their glory was departed for this season. But, no! The snow melted, and I was surprised to find

that, fragile as they seem to be, they were none the worse for the experience. So well do they deserve the name of "The Glory of the Snow."

I have been somewhat surprised that although millions of the *Chionodoxa* must now be grown, that there is such little variation in them, and that they have not been made the subjects of cross-hybridisation, or at least, if so, they have given no great results. White ones have appeared, but personally I consider the peculiar charm of the *Chionodoxa* is the lovely cerulean blue, and therefore, when that is absent, the plant is not nearly so interesting. As I have already intimated, it produces its seed freely, and if this is gathered when ripe, or nearly so, and sown at once in the open, every one of them will germinate. I do not think *sardensis* is nearly so beautiful; it is a deeper blue, and lacks the white which so effectually tends to show off the beauty of *Luciliæ*. Neither do I think that there is any great charm in the varieties *C. Alleni* and *C. gigantea*. The latter has certainly larger flowers, but they are more sparsely produced, while *C. Alleni* has broader and more massive foliage, and the colour of the flower is a shade lighter.

I have never known them in my garden to afford a pasturage for slugs, while the closely allied *Scilla sibirica* has its blooms constantly destroyed by these depredators; but a friend of mine, who is a successful cultivator of herbaceous flowers and bulbs, says he can never keep them in his garden owing to their attacks, while I can say the same about *Puschkinia scilloides*. In fact the peculiar tastes of slugs are very amusing. If one grows a number of *Delphiniums*, and has among them *D. belladonna*, the slugs will travel some distance to get to it, and leave the others untouched. Why in one garden they should devour the *Chionodoxa*, and in another leave it alone, I cannot understand. *Scilla bifolia* is another charming bulb, of which the flowers are of a light delicate blue, small, but freely produced. They are earlier than the other bulbs named, and seem able to stand any weather. There are some which seem to flower earlier than the others, but whenever they do bloom they are acceptable. They succeed admirably in pots, and are a very valuable addition to the greenhouse in the early part of the year.

With the departure of the charming bulbs of this family we may say that the first flush of spring is over. It is true that the glory of the Daffodil has begun, and will continue to brighten our gardens, and those which have been a mass of blue will now be full of golden light; but beautiful as they are, there is not the same sentiment about them that there is about the Snowdrop, Crocus, Primrose, Cyclamen, and Scillas; and though there can be for me but a few opportunities for again seeing them, we must be thankful in having them to gladden our path.—D., Deal.

AMARYLLIS AT CHELSEA.

THE season of Easter may in the horticultural world be taken as representing about the time when the Chelsonian *Amaryllis* will be in flower. It does not indicate the zenith of their beauty to the very day, or even week; but it is sufficiently near to serve as a general guide. Easter does not come at precisely the same time every year, but it is an ever welcomed festival. The *Amaryllis* are not at their best at the same time every year, but they come as an ever appreciated spectacle. In fact, the display has become one of the sights of London at this season of the year, and it is one of the best worth the seeing. For many years in succession we have visited Chelsea to see the *Amaryllis*, and we have always been interested, and never failed to admire the ornately beautiful flowers.

It is not possible now, as it was some few years ago, to see wonderful advances each succeeding season. The standard of excellence that has been attained to does not permit of this. But one can see a change, and it is not in size, substance, and form of flower so much as in the increased number of colours. Dark self-colours have long been abundant, and now Mr. J. Heal, the celebrated Chelsea grower, strives for lighter colours with as much success as could be expected, considering the limited material with which he is forced to work. He has succeeded in getting a trace of yellow in one variety, and he hopes to increase its depth and tone. Now, it is scarcely more than a suffusion in the greenish white basal colour of the segments, and if it can be so developed as to produce a pure yellow, then will the grower have reached almost to the summit of his ambition. A yellow *Amaryllis* or *Hippeastrum* is somewhat like a blue *Chrysanthemum*—much sought for, but not yet likely to be found.

The splendour of Veitch's *Amaryllis* house is such as one can seldom see, and it is a matter for surprise that more of these stately plants are not grown when their beauty is borne in mind. That they are becoming more popular there can be no doubt; but they are not grown in sufficient quantities in the majority of gardens to permit of their full merits being recognised. An isolated plant or two amidst others of a different nature cannot convey an idea of the beauty of a collection of several dozens in one bold mass. They are certainly handsomer than many plants more extensively cultivated, and it cannot be said that their culture involves a great amount of trouble. The details given in the article by Mr. Ireland on page 300 of the *Journal of Horticulture* are admirable, and if adopted will undoubtedly be followed by success. Let us hope they will be more and more grown in the future, for they are well worthy of careful attention.

It has been said that the number of new varieties of greater merit than those existing, is smaller year by year than it was, say, a decade ago, but there are several of which record ought to be made. Some have, of course, been shown at the Drill Hall, but others have not been at their best on a show day, and could not be exhibited though quite as good as those that have received the award of merit of the Royal Horti-

cultural Society. The varieties of which notes were taken were not selected solely because they were of immense size, but rather on account of their richness of colouration, distinctness, or good form. Though size is certainly a desideratum, there are other things to be considered ere a competent judge, such as Mr. Heal, will designate a variety as being in the front rank, and amongst the essential points are those mentioned above. Only about a dozen and a half were chosen, and doubtless since this visit was paid others of equal merit have opened, and of these it is obvious no mention can be made.

Let us commence with *Alares*, which for form of flower could not easily be excelled. Each segment is of good width and exceptional substance, and they combine to make a very beautiful flower. The colour is white, with occasional shadings of soft rose. It is indisputably one of the best. Forming a grand contrast in colour to the last named comes *Harpagus*, which possesses all the desirable attributes of a fine variety. The colour is a particularly rich velvety crimson. Very attractive is *Padusa*, of which the ground colour is white and the markings scarlet. This would find favour with the majority of visitors, as it is quite distinct. Amongst the most imposing must be placed *Emo*, with its brilliant orange-scarlet flowers, that have no trace of the greenish centre to which so many persons object. Of fine shape and striking appearance is *Japetus*, which is crimson-scarlet in shade. The substantial segments are of considerable breadth, and are more even in size than in several of the flowers that were observed.

Favorinus is the one on which the grower pins his faith as promising a fresh break in colour. Throughout the whole of the flower there is a faint suffusion of yellow—not much, but still sufficient to be clearly perceptible. The normal colour of the variety is greenish white, with crimson markings on each of the segments. We shall look with interest to the development of the yellow in future years. A charming *Amaryllis* is *Macenis*. The colour is white, with chaste rose stripes and suffusions from the centre of the segments. One of the darkest in the collection is *Farcinus*, which is velvety crimson. The middle of the flower is singularly deep in hue, and very attractive to visitors. But for the green which forms the centre of the bloom, it is probable that *Jobates* would come very nearly to the top of the tree with connoisseurs, for in shape and substance it is in the front rank. Its colour—pure white with suspicions of bright rose on the upper segments only—too, is very greatly in its favour.

The brilliancy of the scarlet in *Tamaris*, combined with the stout texture and fine shape of the flowers, makes it one of the handsomest in the house, though, so far as the latter points are concerned, it is little, if any, superior to a glowing crimson-scarlet variety that has been christened *Adana*, and a third designated *Zabatus*, and which is also of a crimson colour. The orange-scarlet hue of *Redones* places this with the most distinct, especially when the delicate rose with which it is suffused is observed and appreciated. *Edoni*, scarlet with a white centre; *Raphana*, white with bright red markings; *Uragus*, lively crimson scarlet; and *Varina*, crimson with a flush of purple, are very handsome; while *Clonia*, which received an award of merit from the R.H.S., must conclude the list. The colour of this bold form is white touched with green and striped and margined bright rose. For the dozens of others that are worth an examination readers are recommended to go to the Royal Exotic Nursery at the earliest possible moment.—ANNUAL VISITOR.

RHODODENDRON COLLETTIANUM.

THIS is the name of the shrub represented in the accompanying wood-cut (fig. 65) and which was distributed under the name of *R. afghanicum*, the latter, however, being a new and distinct species from the same region. It is said to be poisonous, and differs from the subject of our note by its campanulated corolla and long exserted bent style. In *R. Collettianum* the style is very short, the flowers in medium-sized bunches of eight to twelve or more, white tinged rose. A well-known writer says, "In most of its characters it closely approaches *R. anthopogon*, from which it differs in its large stature, large straight flowers, and in the tube of the corolla being hairy all down the inside." It reaches 10,000 to nearly 13,000 feet above sea level at Shéndtoi to the ridges of Sikarām, commencing at near the limit of trees, and mixed with masses of Junipers, forming large thickets. For rockeries, or where dwarf shrubs are required in the border this will be found very useful.

HERBACEOUS CALCEOLARIAS.

HERBACEOUS *Calceolarias* present luxuriance of growth, symmetry, and wealth of colour in a remarkable degree; the bold deep green foliage, the large clustering heads of flowers, rich yet soft, and extremely varied in colour, render them worthy of the high rank assigned to them among our floral gems. They are generally treated as annuals, and the certainty and convenience of this method of culture cannot be disputed, old plants being only worth keeping when huge specimens are required for special purposes.

May and June are the best months for sowing the seed, but when it is desirable to prolong the display of flowers other sowings may follow in July and August, in which case it should not be forgotten that considerable space will be required during winter, especially if it is intended to grow large plants such as may be produced in 8 or 10-inch pots; for then,

as the plants gain size, no check must be given to the growth. The few but most important demands for more space for the roots, and for the play of light and air around and among the leaves, must be promptly attended to. When this condition is well looked to the plants make an ample return for every care, by rapidity of growth and the rude vigour with which they flourish. The shifting into larger pots may continue till the flower stems begin to grow, and even after that period, if pinching is practised, as is frequently the case when the aim is to produce plants of an extra size.

The one cultural point of vital importance is to promote the quick yet vigorous growth in the very earliest stages, which is natural to this plant. For this reason I prefer for the seed-pan a compost of old, rich, decayed manure, finely sifted and mixed with an equal quantity of sand, keeping it quite an inch below the top of the pan, sowing the seed on it, and then pressing down gently with a circular piece of wood. A careful damping with water out of a fine rose is then given, and a sheet of glass placed on

FIG. 65.—RHODODENDRON COLLETTIANUM.

the pan, which is taken to a cool house or pit where it can have abundance of light without being fully exposed to the full rays of the sun. So treated the seed vegetates quickly, and the seedlings spring up full of sturdy vigour, are first potted singly in similar soil, and afterwards in a rough rich mixture of manure, turfy loam, sand, and charcoal.

No sifting and very little chopping are required in preparing this compost, in which the roots spread with such surprising rapidity that the plantsman has to be on the alert in the shifting into larger pots; for the roots must not be suffered to fasten on the sides of any pot but that in which the plant is to mature its growth and produce its flowers. To the practised hand the reason for this is obvious enough, but it may be well to point out to the beginner that when a plant becomes root-bound its growth receives a check, often a very necessary one to induce free-flowering, but which is fatal for the time to additional size if such be required. Avoid the use of peat in the culture of these plants. I do not, of course, mean to infer that they will not grow in peat, but a rich coarse soil, such as I have described, is so admirably adapted to their wants as to be altogether preferable. The use of peat in the seed pan is what I most object to, from its propensity to become dry, and the indifferent nourishment it gives to the rootlets of the seedlings.

A glance at healthy *Calceolarias* in any stage of growth is sufficient to convince one that they are gross feeders. Let this but be fully recognised, and be acted upon by affording abundance of rich soil and stimulants, keeping the plants clean—free from aphides and thrips—and with plenty of air and light on all sides, a full measure of success will be the result. The assistance of stimulants, by which I mean liquid manure, is not required till the flower stems appear, when their frequent use is of the greatest value and importance, imparting continued health to the growth, and to the flowers such size, form, and colour as would be quite wanting were liquid manure withheld; it being evident that as the soil of any gross-feeding pot plant is permeated with roots, so surely does it gradually become exhausted. Proof of this is afforded by the decaying or unhealthy foliage, and the short duration of the puny growth of flowers.—L.

NOTES ON PARSLEY.

THERE is probably no product of the garden so frequently in demand as Parsley, unless it be the indispensable Potato, and although there is continuous inquiry for the herb throughout the year, there are many instances where it gets but scant cultural attention. In some gardens Parsley is relegated to out-of-the-way spots, or used as a margin to some other crop, and when sown left very much to chance, the plants not even receiving the attention of timely thinning, so as to give light and space to allow of their becoming strong and fully developed. Sometimes, too, one sowing during the year is regarded as sufficient for all purposes, but those who do so find they have made a mistake at a time when they are left without a remedy.

These remarks, however, have no general application, for the gardener who, whether he has a large or a small supply to find every day in the year, must needs give the subject more than passing notice, and Parsley obtained from the excellent strain now in cultivation certainly provides as pleasant a feature as any other garden crop. The old type, such as one occasionally finds in cottage gardens, although it may possess all that is needed for flavouring purposes, would not call forth any favourable comment either as a garnish or growing plant.

The most densely curled—and this is what constitutes the feature of a summer Parsley—is not usually dependable for outdoor gatherings in winter. Summer and winter uses, however, need special culture and selection of variety, unless, of course, there is adequate provision for growing it under glass, where it is not subject to extremes of cold weather. In such a case the exquisitely curled will be just as suitable for one season as another.

For the earliest summer gatherings I always sow under glass in January or February, which produces strong plants to put out in the beginning of April. They are planted singly in rows from 16 to 18 inches apart, and about 9 inches between the plants. Here they grow strongly, the density of the leaf becomes fully developed, and during the summer months they not only furnish a daily and almost unlimited supply, but the beauty of the plants calls forth unstinted praise from everyone who sees them. Sown in the ordinary way, left unthinned and unattended to, there would be no comparison, and it would be passed by the casual observer, and regarded simply as Parsley. No doubt there is Parsley and Parsley, to use a common phrase, and both may be had from one and the same packet. I have been long since convinced that this everyday plant deserves, as much as any other garden vegetable, the best attention that can be given it.

It may not be generally credited how long these early-raised plants will continue to furnish the daily needs of the kitchen. The present winter could not be taken to prove this, but in severer ones I have had a supply lasting until the new bed is ready the following summer, or some sixteen months from date of sowing. Not that it would be advisable to depend on them for winter and spring use. Three sowings, and sometimes four, would be a safer practice. A late one outdoors would, in the case of those having little room to spare under glass, answer the same purpose, and if sown in a small bed the plants can be protected and transplanted into better soil in March or April, according to the conditions of the soil and the weather.

Parsley germinates slowly in the open garden at any season, but sown in a box of fine soil and placed in a warm house there is no more trouble experienced than with any other vegetable. This slow growth of the seed germ prompts some to lay boards or slates over the drills to maintain a uniformity of moisture, which is so necessary a condition in the raising of any plant from seed. By such a course the crop may be advanced many days, and it may be weeks, when the ground continues in a dry state over a long period.

Parsley, like everything else, delights in good and well-manured land, and I have noticed, too, that a change of soil is as agreeable to these plants as to other crops. To stand the winter firm ground is advisable, and there is not the need for this to be freshly dug or manured, but a plot chosen that has produced an early summer crop. There is much more difficulty in obtaining a "plant" at midsummer than in the spring. Watering of the drills prior to sowing the seeds is an incentive to early growth, but if the soil remain dry and hot for only a few days this will be soon evaporated. A covering with slates, boards, or straw, will, if put on at once, reduce the necessity of watering considerably, and the ultimate results will be more satisfactory. Of disease and insect troubles I have not had much experience. By giving the change of site for each sowing and planting, early thinning, and an occasional light sprinkling of salt and soot, I have generally obtained what is required—an all the year round supply.—W. S., Wilts.

WALLED-IN GARDENS—A FALLACY.

PERHAPS it would interest some of your readers to hear of my experiences with a walled-in garden as a place of protection to plant life. I have two gardens here, one an old one, perhaps between 200 and 300 years old, bounded on all sides by high flint walls. That on the north side is quite 15 feet high; the south, east, and west walls are nowhere less than 10 feet high. The whole garden is not more than an acre.

On the south face of the north wall I have Peaches and Apricot trees; the latter ten days ago were in full blossom. On the south border I have Potatoes, some of which were up 6 inches or more. Six yards to the south of the north wall there is a bed of Roses, which were very forward ten days ago. Now when one is in this garden, surrounded as it

is by these high walls, one would think that if ever there were a sheltered spot this would be it. But, no! The north-east winds we had lately seem to have been turned into a whirlwind within the walls, and have made the Rose bushes look as if they had been burnt, and the Apricot trees have been treated likewise, while Currant bushes have been whirled round and round till their stems have bored big holes in the soil.

Now in the other garden we have, and which is open to the south and not very well protected by hedges and trees from the north and east, nothing has suffered, although Roses, Pear trees, and other plants are very forward on account of the mild winter and spring. I think this clearly shows that walled-in gardens are a fallacy, and not to be recommended.—W. E. NAPIER, *Wiveton Hall, Norfolk*.

CHINESE PRIMULAS.

THE popularity of the many varieties of Chinese Primulas is now so vast, that it matters little where one goes, specimens are practically sure to be found. The amateur with only a small greenhouse always includes in his heterogeneous collection a few Primulas, while the gardener in a large establishment would probably find their place difficult to fill if the stock failed from some unexpected cause. For the greenhouse, the conservatory, and for table decoration the single varieties are almost invaluable, small plants in 3-inch pots being particularly charming for the latter purpose. The semi-double and double varieties, which are comparatively numerous, are not only available for the purposes above named, but are exceedingly useful for supplying cut flowers. Is it any matter for surprise, then, that these plants are so universally popular? Not at all, but rather the reverse—indeed, the numbers that are grown at the present moment might advantageously be doubled.

Like all other flowers, however, they must be well grown if their highest merits are to be developed, for it is an undoubted fact that some Chinese Primulas with which one occasionally meets are scarcely worthy the name. Not that well grown means large plants. Nothing of the sort, for the medium-sized plant in about a 5-inch pot will look handsomer than an ungainly specimen in one 2 or 3 inches larger. Immense leaves have a coarse effect, and the very large flowers sometimes produced on luxuriant plants have not the delicacy and refinement of smaller ones on medium-sized plants. To a certain degree the size of the plant must be governed by the object that the grower has in view, but as a general rule it is probable that the smaller will be the more useful. Each plant must have foliage that is clean and healthy, and be surmounted by flowers of perfect form, substance, and clear in colour. Such as these are happily often seen in gardens and nurseries, and it is in examining a large collection that one appreciates to the full the value of Chinese Primulas as winter-flowering plants.

One of the best illustrations of the perfection to which Primulas can be grown in the neighbourhood of London was seen several weeks ago in the Perry Hill nurseries of Messrs. J. Carter & Co., the Holborn firm that has for so long been famed for its stocks of these as well as other plants. The visitor then could see some 7000 plants, all growing in 48-pots and almost the whole of them in full flower. It was a glorious sight, and was well worth the time occupied by the visit.

Amidst such a plethora of excellent varieties it appears an almost impossible task to select a few that stand above the others for quality, and were a dozen plants alone of each grown, it is probable that everyone would shrink from the task. At Perry Hill, however, each was represented by a mass comprising many scores of plants, and such being the case, the best stood out conspicuously above the others, either by reason of their greater floriferousness, the quality of the individual flowers, the elegance of the leafage, or the purity of colour of the blooms. It is becoming customary in making selections of this nature to place them in order of merit, but in this particular instance no such effort will be made, as they were jotted down as they were observed and points of merit were not allotted. If one were seen that was decidedly inferior to the others it was passed and no mention made thereof, but such as this were rare, in fact only one or two were observed.

Floriferous, and delicate in shade, is Imogen, of which the flowers are rose, but it is scarcely equal in some respects to Princess May, of which the colour is a rather softer shade of rose, the shape of the flowers being very fine. Dwarf in habit, and very free in producing its shapely white flowers, is Elaine, which is known by all and accepted as a general favourite. Bouquet has not yet had a chance to attain to such great popularity, but will be welcomed by many. The white or tinted flowers appear surrounded by the green calyx, and the effect is unique, and of course a perfect buttonhole bouquet is ready for wear. Quite different in all respects is Ruby, with its brilliantly-hued flowers of richest rose. Such names as Carter's Scarlet and Carter's Rose are sufficiently expressive to render explanation superfluous. The Fern-leaved Elaine is as charming as its Palm-leaved sister named above, while Rose Queen, which resembles Princess May in many respects, is certain of admiration. Holborn Queen, of a pure white colour, is very fine in every way, and should be very widely grown, and the same may be said of the Holborn Salmon, Magenta and Carmine, of which the name tells the colour.

Turning from the single to the semi-double varieties we find the same general excellence. Lilac Queen tells its own colour, but cannot convey an idea of its good quality any more than can Vivid, which is a peculiarly rich deep carmine flower of the best form and substance. Aurora, a soft rose, is one of the best of its colour in the whole of the immense collection, Carmine Empress being another that is distinctly above the average

merit. Prince of Wales, salmon rose, is singularly beautiful, as is Princess of Wales, which is white, with occasional spots and flakes of rose. Both these are extremely floriferous, and the flowers are of splendid shape, as are those of the semi-double blue. Snowflake is of great beauty, the colour being a very soft blush.

And so one might go on naming variety after variety, but no special good could accrue therefrom. Some of the best are adverted to, and that is all that is desirable; but a word of advice may be given to those who have not seen the Perry Hill collection this year, and that is, to endeavour to see it in 1899, as they are certain to be delighted and instructed by what they will see.—SCRUTATOR.

NOVA SCOTIA FRUIT GROWERS' ASSOCIATION.

THINKING that your readers would be interested in a report of the meeting of our Fruit Growers' Association, I enclose some notes on the subjects discussed. The Colonies each year take more interest in the mother country, not only as a market for our fruit, but in many other ways, and it seems to me that there should be, and no doubt is, a similar interest in England as to our methods, our prospects, our successes and failures.

The meetings of the Nova Scotia Fruit Growers' Association are always interesting and well attended, and the thirty-fourth annual gathering held in Wolfville, on January 26th, 27th, and 28th, was no exception to this rule. The papers and discussion covered every phase of the fruit growing industry; yet it was quite evident that, in common with, perhaps, every other meeting of horticulturists held on this continent during the past year, the one subject of absorbing interest to all present was the San José scale. President Bigelow voiced the sentiments of all present when he said, in his opening address:

THE SAN JOSÉ SCALE.

"The San José scale has invaded fruit trees in all parts of this continent, and is the most destructive and most difficult to destroy of any insect pest. It is not yet known to be in Nova Scotia, and you will be called upon to recommend strong legislation to prevent its appearance here. In Ontario, where it has been found to an alarming extent, that Government has passed an Act which is very expensive and difficult to enforce, and it is for you to consider whether it would not be cheaper and more effective for us to ask for legislation prohibiting the importation of all nursery stock into Nova Scotia for one year at least. The man who plants an imported nursery tree in Nova Scotia this year is his own worst enemy, and should be dreaded and despised by fruit growers generally." No definite measures were adopted by the Association; but a committee was appointed to investigate the matter more fully, and draft a Bill which should give our orchardists the best protection possible from this most dreaded insect.

APPLES.

While this province is largely interested in the growing of many different fruits, still the after industry stands far in advance of all others in importance. This fact was easily seen in the interest manifested in every subject connected with Apple raising. One entire session was devoted to the discussion of the shipping and marketing of Apples, and many interesting and important facts were presented. Mr. John E. Starr of Port William, U.S., who was lately appointed by the Dominion Government to investigate this subject, was present, and reported the results of his work. He is emphatic in his belief that the principal cause of the injury which Apples sustain in being shipped to Great Britain is lack of ventilation in the hold of the ship while crossing the ocean. This opinion has long been held by experienced Apple shippers here, but it has hitherto been impossible to secure a reform in the matter.

In support of his opinion, Mr. Starr stated that last October he examined a cargo of Nova Scotia Apples when it reached London. The barrels had been stowed so as to allow plenty of ventilation, and as a result the Apples were in prime condition. During November he examined several other cargoes of Apples from this province. The weather being cooler they should have arrived in as good, if not better, condition than the earlier consignment. But it so happened that there were more Apples being shipped at this time, and, in consequence of this increased demand for space, the later cargoes were closely packed. As a result much of the fruit was seriously damaged, and, though still marketable, brought a much lower price than it otherwise would. This difficulty is likely to be greatest in years of bountiful crops, the very time when it is of the utmost importance that the fruit should be placed upon the market in the best possible condition.

ROUGH HANDLING.

At present all the skill of the experienced stevedore is directed toward stowing in the ship every barrel she will hold. Years of practice have enabled him to reduce this to an art, and when the ship is loaded there is scarcely a square inch of unoccupied space in the hold. There is, therefore, practically no ventilation whatever. Mr. Starr recommends that there should be a system of air chambers throughout the ship's hold, so arranged as to connect with one another, and thus carry fresh air to all parts of the cargo. To adopt this plan would necessitate the use of some lumber, but this could be of the roughest kind, and might be disposed of in England for fully as much as it costs. Furthermore, dependance should not be placed entirely upon the full-mouthed ventilators now used for forcing fresh air into the hold. They are well enough when the ship is running against the wind, or even when there is a calf, but let the ship

be running with the wind and there is practically no ventilation whatever. For such an emergency an exhaust fan should be provided, which would draw the air from the hold.

Rough handling in unloading is also accountable for a very considerable part of the damage sustained by Apples. It often happens that while the cargo is being discharged no one is present to guard the interest of the consignees, and the Apples are at the mercy of the gang of men who are unloading the ship, and whose only thought seems to be to get the cargo out in the shortest time and with the least inconvenience to themselves. Frequently the barrels are dropped 3 or 4 feet, till the wonder is, not that the Apples are sometimes injured, but that there is any fruit in the barrels which is *not* injured. If this rough handling and the matter of ventilation could be remedied, there is no reason why the Apples should not be placed upon the English markets in as good condition as when they leave the orchard, or even better.

PACKING AND SELLING.

Honest packing is always important, but it becomes doubly so in years of bountiful crops. At such times, the price being low, the fruit is sent to many parts of England not ordinarily reached, and in this way new markets are developed. If the fruit is satisfactory, the probability is that these new customers will try again the following year, even at a considerable advance in price.

Another point which Mr. Starr urged strongly was that each orchardist should select some reliable firm to whom his fruit might be consigned, and then not change. When a man has established a reputation for good fruit and honest packing his customers will watch for his consignments and, if necessary, will pay several shillings above the market price in order to secure the fruit. All this is lost if the grower ships one year to one firm and the next to another firm. Mr. Starr summed up the requirements for the future as follows:—Good fruit, honest packing, quick travel, good ventilation, careful handling.

It was urged by several speakers that each variety should be shipped in its season, and not held back in the hope of better prices. If Gravensteins are put on the market when Kings and Ribstons are demanded the result is disastrous. And furthermore, if the fruit arrives in an over-ripe condition it must be sold immediately for what can be realised on it, while if it is in good condition the consignee may either sell, ship to other markets, or hold for a time for better prices.

CRANBERRIES.

The raising of Cranberries is each year becoming more important in the province. I have seen many acres of low land, especially in the Annapolis valley, which can be used for no other purpose, and which requires but a small outlay to fit them for Cranberry growing. In the single county of Kings, in 1897, 2500 barrels of Cranberries were produced. Mr. Henry Shaw of Waterville gave the following facts in regard to his 2-acre Cranberry bog. He picked during the past season 174 barrels of fruit, which sold for 1135 dols., netting him 720 dols. above all expenses. Three hundred and sixty dollars profit on an acre is not a bad showing for a single year. Other growers gave similar experience, and it is evident that while the industry is as yet in its infancy it gives abundant promise for the future.

IRRIGATION.

It might be supposed that Nova Scotia, with its moist climate, would have all the rainfall necessary to secure the best results in fruit growing, but the experience of Mr. Henry Shaw, who has just been mentioned, would seem to indicate very strongly that such is not the case. Two years ago he bought a windmill with a 12 foot wheel, and a pump capable of raising over 150 barrels of water per hour. The water was pumped to the highest part of an 8-acre tract of land, and distributed from there in ditches to most parts of the orchard. A few parts could not be reached in this way. The first season, 1896, Mr. Shaw had a full crop on all the trees, as did his neighbour, who did not irrigate. The following year, however, when his neighbour had very little fruit, the trees which had received plenty of water bore another full crop; a few trees which had received a small amount of water produced a half crop, while the trees in those parts of the orchard not reached by the water gave little or no fruit. The outlook for the next year shows similar differences. The trees on the dry land, after a year of rest, promise a fair crop of fruit, but those on the irrigated land, though they have now borne two full crops in succession, give promise of an equally good crop in 1898.

The following officers were elected by the Association for the coming year:—President, J. W. Bigelow, Wolfville; Vice-President, Peter Innes, Coldbrook; Secretary, S. C. Parker, Berwick; Treasurer, George Munro, Wolfville.—F. C. SEARS.

LONDON'S OPEN SPACES.

VI.—CLAPHAM COMMON AND GREENWICH PARK.

IN 1842 it was noted in Knight's "London" that so rapid was the growth of the great city that, doubtless, in a very few years Clapham would become as much a part of the metropolis as Mile End. We, who now regard the continuous line of houses from Blackfriars Bridge to Balham itself, far beyond that, can scarcely conceive it was ever otherwise. The steady march of progress, or the enterprising builder, has blotted out many once honoured spots, such as Walworth Common and Stockwell Green; but, happily, Clapham Common has been preserved to us. If somewhat shorn of its stately dimensions in 1842, it is now a fine open space of 220 acres, only partially railed in. It was at one time rather notorious for its pleasure fairs, held on Good Friday, Easter and Whit

Monday, and Derby days, but these were voted a nuisance and abolished in 1873. A year later the Enclosure Commissioners for England and Wales certified a scheme for placing the common under the Metropolitan Board of Works. A sum of £17,000 was expended in buying up certain rights, and a mandate issued forbidding from that time the cutting of turf, digging of gravel, and shooting of rubbish. An avenue of young trees was planted and three fine ponds made during the draining of the ground, but its rustic simplicity was thought sufficient without any ornamental gardening.

The exposed position of the common has made it the victim of many storms, and any trees of historical interest have long since been swept away. One ruined stump to the north-east of the common may, however, be associated with Thomas Babington Macaulay, who spent the greater portion of his childhood in a house but a few yards from it, near to the Plough Inn. Under its sweeping branches the studious boy would have indulged in many of his waking dreams of "Robinson Crusoe." The County Council, carrying on the work of the Board of Works, have added a roomy bandstand, which is a great source of attraction to youths of the district on Sunday evenings, and they have further greatly extended the opportunities for football and cricket. It was here some American enthusiasts made a few years back a determined attempt to popularise the game of baseball, despite the derisive remarks on the man in armour who acted as "wicket keeper." Clapham is supposed to have derived its name from Osgood Clapha, the Danish lord, at whose marriage feast Hardicanute died. The district, and undoubtedly the common, too, has associations, beside Macaulay, of Pepys, who often stayed there with his friend Gauden, and of Mr. William Wilberforce, M.P., the distinguished philanthropist and father of Bishop Wilberforce.

Ancient and honoured, Greenwich Park is still one of the most charming resorts in the district of London. Peter the Great was not wholly a barbarian when he wondered why Dutch William did not have his royal palace there, not knowing that it was long a royal residence. When Greenwich Park was first enclosed by Humphrey, Duke of Gloucester, in 1433, Greenwich was "a prosperous town in Kent, five miles from London." The duke erected a palace, which he called Placentia. This was enlarged by Henry VII. and completed by Henry VIII. Here Queen Mary and Queen Elizabeth were born, and here Edward VI., who just lived long enough to found the Bluecoat School, died. Mr. T. Miller, in his "Picturesque Sketches of London," thus writes of the park: "What scenes these aged Hawthorns have looked upon. They are the ancient foresters of the chase, and many of them have stood here through the wintry storms of past centuries, and were gnarled and knotted and stricken with age long before Evelyn planned and planted those noble rows of Chestnuts and Elms. Below, between the plain at the foot of the hill and the river, stood the old palace of Greenwich, in which Henry VIII. held his revels, and where Edward VI., the boy king, breathed his last. That ancient palace was, no doubt, rich with the spoils of many a plundered abbey and ruined monastery. . . . On this hill, again, Cardinal Wolsey may have meditated with all his blushing honours thick upon him. Katharine, the broken-hearted queen, may here have reined in her palfrey, or from this aged Hawthorn have torn off a sprig when fragrant and white with Mayblossom, as now, and have presented it with a smile to the royal savage who rode beside her. On yonder plain, where so many happy faces are now seen, in former days the tournament was held. There gaudy galleries were erected, over which youth and beauty leant as they waved their embroidered scarves. We can almost fancy we can see the crowned tiger smile as he closes the visor of his helmet, bowing his plume while he recognises some fair face which was soon to fall on the scaffold with its long tresses dabbled in blood."

The Royal palace fared very badly during the Civil war, and, becoming ruinous, was pulled down by Charles II., who began a magnificent edifice, and lived to see the first wing finished. The Merry Monarch also enlarged the park, bringing it up to 185 acres, walled it round, planted it afresh, and erected a Royal observatory on the top of the hill for the use of the celebrated Flamstead. The observatory occupies the site of the tower commonly called "Greenwich Castle," which was built by Duke Humphrey. It was constructed in haste, chiefly with the materials of the old tower and some waste bricks that lay available at Tilbury Fort and the Tower of London.

The avenues still remaining in Greenwich Park are composed chiefly of Elm and Spanish Chestnut, the latter being mostly confined to the upper part of the Park. But there is one avenue—perhaps the finest—which, widening out at the base to correspond with the width of the hospital, is there composed of Elms, but as it ascends the hill is made up wholly of Scotch Firs of an exceedingly picturesque and noble type. Walking under these trees Dr. Johnson, who then had lodgings in Church Street (it was 1737), composed a great part of his "Irene." "One Tree Hill" "inspired" George Cruickshank to the following rhyme in his "Comic Almanack":—

Then won't I have a precious lark
Down One Tree Hill in Greenwich Park!

The significance of this title is now somewhat destroyed by the fact that six trees grace its summit, planted when the original solitary tree decayed. When the Queen came to the throne the park was much resorted to for fairs on the Monday, Tuesday, and Wednesday of Easter and Whitsuntide weeks. The fairs have long been out of date. In later times the glorious park has been unpleasantly associated with an Anarchist attempt, for it was here on February 15th, 1894, that the ruffian, Martial Bourdin, was fatally wounded by the premature explosion of a bomb he had prepared for Greenwich Observatory.—("Lloyd's News.")

THE YOUNG GARDENERS' DOMAIN.

CAMELLIAS.

THESE charming and certainly very popular evergreen shrubs have an imposing effect when well grown in houses devoted entirely to their cultivation. The best method is by planting in specially prepared borders, although they may be grown very successfully in pots or boxes if properly treated.

Camellias delight in shade, and retain their flowers three times as long as if exposed to the sun. They may be produced in abundance for at least six months. Those which expand early in the season are always of the best quality, and usually last the longest. Fire heat is seldom necessary except to exclude frost, but when flower buds are forming a genial warmth is beneficial, and should be continued until growth is completed, when the house may be gradually reduced to its natural temperature. If the buds form in clusters they must be thinned out. Always pay strict attention to watering and ventilation. Although abundance of air is essential for the Camellia, cold draughts are dangerous, and must be avoided if possible. During their growing season an occasional application of weak clear liquid manure and soot water may be given with advantage. Camellias are subject to insect pests, which should be diligently sought and destroyed if good results are expected.—J. F. D., Yorks.

GRAFTING GROS COLMAN ON A LADY DOWNE'S VINE.

THE Vine Lady Downe's was twenty years of age, planted in an outside border. About the middle of December, 1895, the Vine was cut back to within about 2 feet from its base, to form a stock for grafting. The following February the vinery in which the stock was situated was started. By the middle of March the stock produced several shoots, the three stronger of which were selected for grafting, the remainder taken off. When the three young shoots were about 18 inches in length they were grafted with Gros Colman scions, the split-grafting method being adopted. One out of the three scions soon united and started into growth, which went on very rapidly, and by the end of the summer had formed a short jointed well ripened cane. As soon as the leaves had fallen the cane was pruned back to fifteen joints from the union of the scion with the stock. In the following spring the cane broke very strongly, the whole of the joints starting, and fourteen of them showed fruit, but six only were allowed to carry their fruit. As a result we had six bunches of good shape and excellent colour, weighing, on an average, 3 lbs. each. The crop did not exhaust the Vine in the least, as it looks very promising for a still better crop this season. I have also seen very good results by grafting Gros Colman on a Foster's Seedling stock, but rarely on a Black Hamburgh.—A JOURNEYMAN.

[A concise description of successful practice, but no doubt other journeymen would have been glad if the condition of the scions had been made as clear as the rest of the communication.]

FUCHSIAS.

IN response to the call of "An Old Boy," on page 226, touching the desirability of learning to use the pen as well as the spade, I, for one, venture to enter the "Domain." Not having contributed before, one feels a little uncertain as to whether one's efforts will be crowned with success or not; but after so stirring an appeal it behoves us to try and do our best.

Fuchsias are not unfrequently neglected in gardens, on the plea that "cottagers can grow them," and for that reason no effort is made to cultivate them. But that is an erroneous idea, and one that should not be entertained. The comparatively small amount of skill required in the cultivation tends to the detriment of the Fuchsia in a slight degree in the estimation of some; but it should not be despised, for it rivals many of its more favoured associates of the greenhouse in wealth and beauty of flower, and also in length of period of beauty, for with judicious care and forethought plants may be had in flower for three months out of the twelve.

It is easily propagated by cuttings, which process is no doubt familiar to "Domain" readers, and therefore it is unnecessary to enlarge upon it. Although not a common practice, Fuchsias can be grown from seeds every year. Sow in heat in January or February, and when large enough to handle prick the seedlings round the edges of 3-inch pots, moving as required until the final size is reached. Shade and moisture are essential to their well-doing.

After they have ceased flowering they should be gradually dried, and stored under the late vinery staging or some other dry place for the winter. In the spring the plants ought to be repotted and grown again. They should have a frame to themselves, and be kept moist and well syringed on bright days. A light top-dressing of rich compost or some approved artificial manure is beneficial just before they commence flowering, and they should also have occasional applications of liquid manure, for the Fuchsia is a gross feeder, and must have abundance of food. They can be grown year after year, and by raising young plants, and throwing the old ones away, a continual supply of useful stock will be the result. Green fly is the worst enemy to Fuchsias, and as soon as it makes its appearance the plants should be promptly fumigated.—A. E.

[Men who do not "try" cannot expect to succeed; those who will to excel in anything can only do so by intelligent practice and perseverance.]

FRUIT FORCING.

Cucumbers.—Instead of striving to renovate plants that have been in bearing all the winter, it has become a practice to uproot them, which answers admirably for market purposes. But home growers are obliged to make shift with the old plants until a supply can be had from frames or pits, so the winter fruiters have to be renovated at the roots, and that without prejudicing the successional supply of fruit. Stopping, training, and cutting out the old growths must be followed up, and copious waterings given as necessary. Assist plants in full bearing with abundant supplies of weak liquid manure, and earth the roots occasionally. Damp the floor about 8 A.M. and 3 P.M., the foliage being syringed lightly on fine afternoons, and keep the evaporation troughs charged with guano water or liquid manure. Shading will be most needed after a period of dull weather to prevent flagging.

Melons.—In the earliest house the plants are swelling their fruits and require supports. Remove all surplus fruits and all flowers, also superfluous growths, stopping and tying as necessary. Afford efficient supplies of water, giving liquid manure as necessary for the maintenance of a free growth. Genial atmospheric moisture must be maintained by damping early in the morning and afternoon, syringing the plants lightly about 3 P.M. on bright afternoons. Later plants showing fruit should, unless abundant and the plants vigorous, have the first blossoms removed. Secure a somewhat higher temperature and drier atmosphere during the setting, only affording as much moisture as will prevent flagging. Stop the shoots at one joint beyond the fruit, but employ the knife as little as possible during the setting period.

In pits and frames ample bottom heat must be maintained, observing the conditions previously given during setting. When the fruits are set and swelling they should be placed on a piece of slate. If canker appear at the collar rub quicklime into the affected part until quite dry, repeating this as necessary.

Peaches and Nectarines.—*Earliest House.*—Where such varieties as Alexander, Waterloo, and Early Louise Peaches, with Advance and Cardinal Nectarines are grown, the stoning process will be over, and to accelerate the ripening they may be given a night temperature of 65°, but falling to 60° on cold nights. Admit a little air constantly. Close the house at 80°, sufficiently early to allow of an advance to 85° or 90°, the trees being well syringed and good atmospheric moisture secured. Remove the leaves over or in front of the fruit, and turn this with its apex to the light by thin laths placed across the trellis. Syringing should cease when the fruit commences ripening, but a genial condition of the atmosphere must be maintained for the benefit of the foliage by damping the paths and borders twice a day and keeping the soil properly moist.

Second House.—The trees in the structure started in January, and brought forward gently, have the fruit in a forward state, the disbudding completed, and the shoots that are to follow those now fruiting laid in. Always allow plenty of room in the ties, and do not keep them closely tied down for some time longer. Allow no more growths to remain than are necessary for next year's fruiting, or for the extension of the trees. Stop gross shoots or remove them, as it is highly important the sap be equally distributed, and an equality of vigour maintained through the branches of each tree. Pinch laterals at the first joint, and shoots retained to attract the sap to the fruit should only be allowed moderate extension. Endeavour to provide an equal distribution of foliage that will shade and protect the strong wood from the direct rays of the sun as the season advances. Ventilate freely, but carefully, so as to avoid cold currents of air and sudden depressions of temperature. Water the inside borders copiously, and keep them mulched with sweet rather lumpy manure.

Trees Started in February.—Examine them frequently for disbudding, and this is best done gradually, the strongest parts of the trees being commenced with. As the fruit is swelling freely, remove those worst situated, and leave only a few more than will be required for the crop, one to every square foot of trellis covered by the trees being ample for the large-fruited varieties, and one to every 9 inches square for the medium-sized and Nectarines. Syringe early on fine mornings, give a little air [shortly afterwards, gradually increase it, and close about 3 P.M.; but if the weather be very bright later closing must be practised.

Trees Started in March.—The trees are out of bloom, set the fruit well, and aphides made appearance. Fumigation or vaporisation must be practised carefully, and on two or three consecutive evenings. Syringe moderately in the morning, and on fine afternoons, always early enough to allow of the foliage becoming dry before night. Disbud gradually, and rub off all small and badly placed fruit as soon as the most prominent shows signs of taking the lead. Ventilate freely on all favourable occasions, and close early with a view to husbanding the sun's heat, but avoid a close vitiated atmosphere, admitting a little air constantly to prevent it.

Late Houses.—The trees are in full blossom. Ventilate freely and keep safe from frost. To insure a good set it is advisable to turn on the heat in the morning, so as to raise the temperature to 50°, and keep it at that, with a gentle circulation of air, turning off the heat early in the afternoon, so as to allow of the pipes cooling before night, and the

temperature falling to its night minimum of 40° to 45°, which is quite safe, and ought to be secured after the blossoms expand, with a little air to prevent the deposition of moisture through the night on the flowers. Artificial fertilisation should be resorted to as necessary.

THE KITCHEN GARDEN.

Asparagus.—Fresh beds may be formed during this month, fewer failures occurring when the plants are moved after top growth has commenced than when they are transplanted earlier. In any case the delicate root fibres ought to be exposed as little as possible to cold drying winds, and any plants that have been sent from a distance and become very dry should directly they arrive be spread thinly on the surface of the ground, and sprayed with water prior to covering, first with fine sandy soil and then with mats. If kept moist the roots will plump up, root fibres form, and the plants be in a fit state to put out in a week or ten days. In any case more than ordinary pains ought to be taken in planting Asparagus, burying the plants roughly meaning probably the loss of a season. Cold clayey soils require the most preparation, and light sandy ground the least. Correct the retentiveness of the former by a free admixture of sand, fine mortar or lime rubbish, charred soil and ashes, leaf mould and fine peat, well mixing this with the top spit rather than burying it deeply. Raised beds are most desirable in low damp places, and are largely formed in other positions. These beds may be 4 feet wide, with alleys 18 inches wide between, and will hold three rows, the two outer ones being arranged about 9 inches from the edges. Lighter soils may be deeply dug or trenched as for ordinary garden crops, mixing solid manure freely with the bottom spit, and some fine well-decayed manure with the top soil. Raised beds can be dispensed with in the case of warm non-retentive soil, arranging the rows 2 feet to 3 feet apart on the level. Extra space must be allowed if large Asparagus is desired, but a greater bulk of good produce can be cut from a given space of ground when the plants are disposed 15 inches to 18 inches apart in the rows. In planting take care to spread out the roots in a natural manner, covering them and the crowns with about 3 inches of the finest soil. Slugs are destructive to young Asparagus growths, and should be warded off with the aid of soot and lime.

Sowing Asparagus.—Seeds should be sown at once, or directly the ground can be got into a suitable condition, either where a portion of the plants are to remain, or in a well-prepared site, from which the plants may be moved after one or two seasons' growth. In the former case prepare the sites much as advised in the case of beds to be planted, sowing two or three seeds where plants are required. In the other instance sow the seeds thinly in drills 1 foot apart. Seeds may also be sown thinly over the surface of beds not so fully occupied by plants as desirable, the seedlings duly thinned out and allowed to grow without being cut from for two years, putting new life into the beds.

Broccoli and Borecole.—Only the autumn varieties of Broccoli should be raised, and planted early. Late in April or early in May is quite soon enough to sow seeds of midseason and late varieties, leggy, overgrown plants being the first to feel the ill effects of frost. Sprouting Broccoli is an exception to the rule, this requiring a longer period of growth, and should be put out early. Borecole sown now, or a fortnight later, will be ready for planting quite as soon as the ground in most gardens can be spared for the crop. The value of Asparagus or Buda Kale should not be overlooked, this rarely succumbing to frost, and the sturdy plants yield abundance of succulent tops long after the other winter greens have run to seed.

Cauliflower.—March and the early part of April proved most unfavourable for planting Cauliflowers wintered under glass or otherwise protected, and those who risked them in the open will have many failures, and more plants must be put out. They move best out of pots, and time will be gained by first establishing recently raised plants in 3-inch pots under glass before trusting them in the open. Autumn Giant sown in the open now, and planted out when large enough on well prepared ground, would heart in during October and November, a portion of the stock being available for lifting and storing in pits in the autumn.

Savoy Cabbage.—Tom Thumb, and other dwarf early-hearting varieties, may be sown now, as these are frequently of good service in the autumn, but the midseason and late varieties may well be sown at the same time as late Broccoli. If raised and planted early they are liable to become very coarse, hearting-in earlier than desirable, and not withstanding frost.

Carrot.—Very large roots are of little or no value for cooking purposes, the preference being given to those medium and small in size. Early sowing is conducive to coarseness of roots. The middle of April is soon enough in most localities to sow seed of recognised main crop Carrots, and with these may also be sown the larger Horn or stump-rooted varieties. Carrots should have a well prepared site—that is to say, the ground must be brought into a finely divided state to a good depth. If the ground were well manured for the preceding crop no manure ought to be needed for Carrots, and the least that can be done if fresh manure is used is to dig this in deeply, contact with manure causing the roots to fork. The drills for strong-topped varieties should be 12 inches apart, 2 inches less sufficing for the Horn varieties. If the Carrot maggot has proved troublesome in previous years, dust fresh wood ashes lightly (an excess may do harm) along the drills before covering the seed.

Salsafy, Scorzonera, and Chicory.—Early sowing is not desirable in either case. If the seeds are sown now the roots will become quite large enough, and comparatively few plants will run prematurely to seed. For these, again, no solid manure ought to be needed, and none should come into contact with the tap roots anywhere near the surface. Draw shallow drills 15 inches apart, and sow the seed thinly in these. Chicory

seed is comparatively small and germinates readily; thick sowing, often resorted to, entails much labour in thinning that might have been avoided.

Vegetable Marrows.—It is too early to sow seeds with a view to having plants for turning out in the open late in May or early in June, but early Marrows are most appreciated, and if a frame or hand-lights can be spared to cover the plants for a time, some should be raised at once. Sow the seeds singly in 3-inch pots, and place them in gentle heat to germinate, raising the plants well up to the light before they become drawn. In the meantime collect a large square heap of leaves, sweepings, vegetable refuse, and strawy manure, or enough to form a bed for both early and main crop plants.

THE BEE-KEEPER.

REMOVING SPARE COMBS.

SOME of the most successful bee-keepers in this country leave the whole of the frames in the hive throughout the winter; others equally fortunate in the condition of their stocks in the spring remove the outside frames from their hives in the autumn and close up the division board, so that the bees may be enclosed in a smaller compass and thus be able to withstand any extremes in temperature. If extra-sized hives are used the latter plan is recommended, but if the ordinary hive holding ten standard frames is in use then it is not necessary. It is many years since we first experimented on these lines, and during the past winter we had several hives holding upwards of a dozen frames, the whole of which were left in the body of the hive. Others, again, had the division board placed between the empty combs and those containing the stores, whilst those having a less number of frames were not disturbed.

It was therefore interesting to observe how the various colonies had come through the late exceptionally mild winter. Strange as it may appear there was no difference in them, all were in good condition. The mild weather had doubtless something to do with this, although it is only fair to say that in previous winters when the temperature has been low there has not been as much difference as one would have expected.

It is an advantage after this date, whether the hives are large or small, to close up the frames containing bees, brood, and stores with the dummy or division board. The outer frames will now be empty, and these need not be taken away, but placed at the back of the division board; they will then be conveniently to hand for use in the brood nest when required. It is important that the whole is covered up warm with several thicknesses of old carpet or similar material, and if a board is placed on the top of all and weighted down with a brick, it will be an advantage in conserving the heat. The middle of a fine day should be chosen for examining stocks, and if carefully done the bees need not be disturbed.

UNITING WEAK COLONIES.

It is quite a common occurrence where several colonies of bees are kept in an apiary, for some of them to be much stronger than others. This is more apparent at this season than at any other time of the year. Why it should be the case it is somewhat difficult to say. The queens may all have been carefully bred early in the season, and fertilised in due course. These stocks have gone into winter quarters crowded with bees and well supplied with stores, but when examined in early spring some of the colonies will be extra strong in bees, whereas with others the opposite will be the case. This is the experience of all bee-keepers with whom we have come in contact. There are others who have no system of queen rearing, and leave the matter very much to the bees themselves; the consequence is many old queens die during winter and early spring, and the natural consequence is numerous weak colonies in the apiary.

But what is best to be done with these weak stocks? We have no hesitation in recommending them to be united, having on many occasions derived great benefit by doing this early in the spring, instead of waiting until the season has well advanced. If the stocks are queenless, then unite them to the next colony having a fertile queen. But if two or more stocks are headed by queens, and the bees have dwindled until few remain, destroy the older queen, and unite the bees to the one having the more prolific queen.

If the stocks are several yards apart, and the weather is bright, so that the bees are on the wing, remove them a few feet nearer each other daily. In the evening remove all the empty frames from the hive containing the queen. Separate the other combs, and sprinkle the bees with flour or thin warm syrup. This may be repeated with the queenless colony, the frames being lifted out and placed alternately with those in the other hive. Cover up warm, and place a bottle of warm syrup on the top, and all will be well. Stocks treated in this

manner invariably do well, if not left too late until there are not sufficient bees to keep up the temperature of the hive. When this is the case more bees must be added, or it will end in failure.

ROBBING.

What bee-keeper is there who has kept numerous colonies of bees and has not had a bad case of robbing? We have experienced it on several occasions, but more often in our novitiate days than now. Bee-keepers have often themselves to blame through carelessness in some form or other. It may be in spilling some syrup, or allowing a weak colony to remain on its stand after the bees were too few to protect their stores. Once let the robbers, which come from the strong colonies, gain an entrance, they will in a short space of time clear out the stores, and the rightful owners will (if not attended to) soon die of starvation. At first they will try and defend their stores, but when they find the case is hopeless they will not interfere with the robbers. It is surprising at what a rapid rate they will clear out the stores from a weak colony.

It is a decided advantage to reduce the entrance to an inch at this season, allowing more space as it is required; this will give the bees a better opportunity of defending their stores than if the entrance were open its full width. In a bad case of robbing it is often necessary to remove the stock attacked several yards away from its original stand, placing an empty hive in its place. Before doing this some carbolic acid should be smeared on the alighting board, only allowing about an inch of clear space opposite the reduced entrance. This will often have the desired effect without the necessity of moving the stock bodily away. When this is done care must be taken that the colony attacked is well supplied with stores, which should be given in the evening.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

* All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Justicia calytricha (Nemo).—In the cultivation of this charming plant it is advisable to raise fresh stock from cuttings annually, for old plants seldom grow with such vigour or produce such large plumes of flowers as do young plants. Old plants from their slow stunted growth often become a prey to scale, which is not the case where the plants are raised from cuttings every year, provided they are not grown too warm. Old plants that have flowered should be encouraged to grow in a warm house, for the sooner cuttings can be obtained the better. When strong cuttings have been produced they should be inserted singly in small pots, and if kept close in the propagating frame every one will root. They should be grown warm until they are established in 8-inch pots, and from this stage an intermediate temperature should be given them. After the middle of July they should be grown in cold frames.

Leucophyton Browni (*H. H.*).—In the propagation of this serviceable carpeting plant it is essential to bear in mind that it is most impatient of fire heat, and the cuttings are certain to fail if subjected to it. The proper time to insert the cuttings is during the month of September, and they ought to be treated exactly the same as *Violas* or *Calceolarias*. Either three parts fill frames set on a hard dry base, with nearly exhausted heating material, or set hand-lights on a bed of the same. Cover with about 3 inches of fine sandy soil, face over with sharp sand, and dibble out the cuttings thickly, keeping them rather close and shaded from bright sunshine till rooted, and in all other respects treat similarly to *Calceolarias*. They would receive the least check when bedded out if first established in thumb pots, but keep them out of the houses.

Anemones from Seed (*New Reader*).—Certainly, single *Anemones* can be readily raised for seed, and plants from seeds sown now will commence flowering next year if grown in fertile soil. The year following they will be very fine if the tubers are not disturbed. The seed being very woolly must be separated by rubbing it with sand, and then scattered in drills about 6 inches apart and 1 inch deep, saturating them before sowing if the soil be dry. Should bright weather follow it will be advisable to shade the beds with mats or some other material, or the seed will not germinate freely, and shading is much better than watering after sowing. If the seedlings are crowded patches of them may be dug up with earth adhering to the roots, and transplanted in showery weather in summer. Fresh seed should be obtained, as the old does not germinate freely.

The Caper Plant (*J. W. W.*).—We imagine you must be a comparatively new reader, as we have more than once stated that *Capparis spinosa*, from which the capers of commerce are obtained, grows abundantly in the south of Europe, along the shores and on the islands of the Mediterranean, and in Syria. It is generally found wild on walls and rocks; it is met with on the walls of Rome, Sienna, and Florence, and is extensively cultivated in the south of Europe, particularly between Marseilles and Toulon, and in many parts of Italy; but it is from Sicily that the greatest supply is brought. The flower buds form the capers so much used as a pickle and a sauce, but in some parts the fruit is also employed. In the early part of summer the plant begins to flower, and the flowers continue to appear successively till the beginning of winter. The young flower buds are picked every morning, and as they are gathered they are put into vinegar and salt; and this operation continues for six months, as long as the plants are in a flowering state. When the season closes the buds are sorted according to their size and colour, the smallest and greenest being the best; these are again put into vinegar, and then packed up for sale and exportation. Capers are stimulant, antiscorbutic, and are much employed as a condiment, but the medicinal virtues of the plant reside in the root, which is slightly bitter, somewhat acrid and sour, and is diuretic.

Convolvulus cneorum (*H. S. W.*).—This is commonly known as the Silvery Bindweed, and is a dwarf shrub from Greece with lanceolate leaves. It grows about 18 inches high, and is of semi-procumbent habit, which renders it very effective on the dry sunny aspect of rockwork, where it is hardy in all but the severest winters. The plant is evergreen, and bears a number of shining white flowers, which have the glitter of pearl, and, like it, are slightly tinged with red. Of free growth it soon forms a spreading low bush. Cuttings rooted in late summer, wintered in a cold frame, and planted out in the spring, form a bush nearly a yard across by September, during which it commences flowering and continues until frost. In order to guard against mishap from frost it is well to root cuttings in August under a hand-light, pot them when rooted, and winter in a cold frame or house. Plants raised in this way, grown in a cool house, and shifted into larger pots as required, are very showy for conservatory decoration. The flowers are borne like those of *C. mauritanicus* at the points of the growth, hence stopping must not be continued longer than is needed to lay the foundation of a compact plant. Although not nearly so trailing in habit as *C. mauritanicus* it makes a desirable basket plant, but is best seen as a rock plant. It does well in loam with a little leaf soil or decayed manure, and a little sand to keep it open.

Layering Chrysanthemums (*R. Thompson*).—This operation is comparatively easy, and with ordinary attention you need have no fear of failure occurring. Plant a few old plants out of doors in a row; let them grow as wild as they choose till the month of July; then take as many pots as plants are required, and plunge them, filled with some rich soil, into the ground at such a distance from the plants growing in the ground as will allow the tops only, when bent down, to reach the pots; bring them carefully down, and peg each branch firmly into the soil. Leave about 2 inches of the top out of the soil. If the shoot is branched it is well, but if not it must not be topped, because there is some danger that the layer may continue to grow and not flower if topped so late in the season. The aim of this mode of propagation is to make them flower when very dwarf, and therefore the layer should have buds upon it just visible at the time when layering is performed. Keep the soil in the pots moderately moist till roots are formed, and after that water more freely. When it is certain the layers have made plenty of roots, cut them off from the parent plant, and remove them into a frame or pit deep enough to receive them. Should they flag during the day, give a sprinkling of water, and shade for a day or two till they recover; then give air and water freely. They will then be good plants, about a foot high, with, perhaps, six or ten flowers on each.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a

flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*S. H. P.*).—1, *Doronicum Clusi*; 2, *Pittosporum Tobira*; 3, *Cydonia Maulei*. (*W. J.*).—1, *Primula farinosa*; 2, *Omphalodes verna*; 3, *Primula japonica*; 4, *Kerria japonica flore-pleno*. (*C. M.*).—1, *Odontoglossum pulehellum*; 2, *Cypripedium villosum*. (*P. P. R.*).—1, *Celsia arcturus*; 2, *Sedum lydium*; 3, *Herniaria glabra*; 4, *Spiraea prunifolia*; 5, *Ribes aureum*; 6, *Forsythia intermedia*. (*R. L.*).—1, *Euonymus latifolius variegatus*; 2, *E. japonicus aureo-variegatus*; 3, *Erythronium grandiflorum*; 4, *Primula capitata*; 5, *Pulmonaria officinalis*; 6, *Muscari conicum*, poor form. (*W. M.*).—1, *Tropæolum tricolorum*; 2, not yet identified; 3, *Diplopappus chrysophyllus*.

SOMETHING WRONG.

We most of us know by sad experience the horror of the short sea passage in well appointed boats, either over the English Channel or the stormy waters that separate us from the Sister Isle. To some of

us the journey, short as it is, is fraught with terror. The seas that rise mountains high threaten to engulf us—that is if we are well enough to be conscious of anything save our own prostration, and we never take the voyage voluntarily. Everything is done to secure our comfort. The steamers are built on the best possible principles, the captains are picked men, yet nevertheless we suffer for a time unmitigated woes.

We have been much saddened by the perusal of an article in "Chambers' Journal" for February, which has just come under our notice. The subject is "Revelations of the South American Cattle Trade," and if only half of the facts stated therein are correct, the picture is a most dismal one. We know magazine articles are often written for effect, and the matter passed out of our minds till it was recalled by a note in "Agricultural Gazette" for March 28th. It appears from that paper that the facts in question have been brought before the House of Commons by Col. Cotton-Jodrell. He asks Mr. Long whether he is aware of the awful mortality of stock on board ship between S. America and our ports. Mr. Long is forced to admit that the figures quoted are correct, and he holds out hopes that the evils complained of may be mitigated.

In the meantime we hardly suppose the average Englishman has the slightest idea of the terrible state of affairs at present existing. Col. Cotton-Jodrell's figures run somewhat thus: Of cattle imported from South America. Of cattle arriving at the home ports during 1897 the losses en route were 10 per cent., and of sheep the losses were a little over $3\frac{1}{2}$ per cent. The voyage occupies about thirty days.

We import much stock from the States and Canada, and the losses during that voyage amount to only 2·3 per 1000 for cattle, and 7 per 1000 for sheep. Of course we know the voyage is much shorter, but not so much shorter as to make such a sensible difference in the figures. The N. Atlantic steamers engaged in the cattle traffic are bound to be fitted up in the best possible manner, and are subjected to close inspection. On them, at least, all is done that can be done to mitigate the hardships of the passage. Now, the S. American traffic has not yet been so regulated. The great evils are unsuitable ships, bad fittings of the match-box type, and no appreciable ventilation.

Of course there are some steamers engaged in the River Plate that are specially fitted, but alas! they are outnumbered by boats designated as "tramps." The name tells its own tale—they are simply unsuitable in every detail, and become veritable shambles. No doubt officials of the Argentine would tell of proper codes of regulation, re-loading, and so forth; but they might hesitate to tell that a little golden eye salve makes them conveniently blind. These South Americans have a low standard of commercial morality.

Cattle below deck, sheep on deck, so closely packed as to make navigation almost impossible. Then picture a voyage through the tropics, the stifling heat, the bitter cold of the Northern seas—it is a wonder any cattle survive. Then throw in rough weather, the ship rolls and pitches, the divisions give way, horns and legs and bodies shaken up in inextricable confusion; think of the broken bones, the horrid wounds, and the general suffering. The sheep have the best of it. A storm and wave-swept decks soon end their sufferings, but the cattle below are in an inferno.

It is not only in bad weather these sufferings are so terrible. Many die from suffocation, and what must they have gone through before merciful death released them? One does not fancy handling dead stock at the best of times, but to get a dead beast out of the bowels of the ship is too fearful to think of, and yet it has to be done, and done quickly, or the health of the crew will be in jeopardy. We wonder in what sort of condition the survivors land, or where are they hidden till they have got a bit of bloom on again? The beef and mutton is dearly bought at the price of so much cruel suffering, and someone is guilty of what amounts in our eyes to a crime.

Men of such callous heart can only be touched by the strong hand of law, and the question seems to be who is to mete out the punishment, and where? We are the policemen of the world. We

have stopped many other atrocities, and this is one that seems to call for stringent legislation.

We want the co-operation of the various S. American Governments, which one would think it might be easy to obtain. At any rate we can insist on English vessels complying with the sanitary regulations observed by the boats engaged in the N. American trade. We note that all the sheep this week at Deptford market were from the Argentine Republic, and they were 5d. per lb., as against English in other markets at 8 $\frac{3}{4}$ d. There were 3379 of these poor exiles on sale.

To come home—we are not altogether without blame. Have we never seen at the eastern ports shipments of poor worn-out horses for the Continent? There is more of that going on than we suspect, but the P.C.A. Society has its eye on that branch of industry, and probably we shall hear more of the matter anon. It needs investigation, and any organisation that will mitigate the sufferings of man's most useful servant ought to receive unlimited support from the public.

WORK ON THE HOME FARM.

The rain of last week, though not heavy, was sufficient to improve the tilth of Turnip land still unsown with Barley, and the spring sowing is being now finished very favourably.

We have had one or two rather sharp frosts, and early sown Oats seem to be feeling the effects of it. A little more rain is what we still want. The land is very dry, and there will not be too much moisture to start the growth of the Mangolds, which will have to be sown this month. The earlier they are put in the better after April 1st, if the land be good and well drained.

We have the land for Mangolds very clean, so we shall not risk loss of moisture by moving it uselessly now. We shall plough at once, roll it quickly, then ridge it up, manure it, and drill the seed, getting all the operations performed as rapidly as possible. We shall steep the seed in water a couple of days before drilling, as the moisture makes germination much more certain. Four cwt. of common salt per acre is a good thing for Mangold on light land.

We are harrowing Wheat now whenever it is dry enough, and are giving about 90 lbs. per acre of nitrate of soda. Wheat will pay for a little help when it is worth 40s. per quarter.

Pastures have suffered from the frosts; there is not too great a supply of roots left, and many farmers are having their stock forced on a glutted market sorely against their will; here again we want rain. Clovers have died off a good deal this winter; this cannot have been caused by frost, and must be from Clover sickness. Cross cropping and Potato growing are good antidotes for Clover sickness, but lime is the best of all. We like to use it for the Turnip crop, and generally apply 3 tons per acre. It has a marked effect where the Turnip finger-and-toe or Clover sickness is prevalent, but especially marked is its influence on the Clover.

Hens are laying well, but eggs are cheap at eighteen for 1s. The early chickens grow fast, and are nearly ready for the cook.

REMARKS.

3rd.—Fine and mild, with cloud and sunshine; clear night.
4th.—Fine and generally sunny, but a slight shower of rain and hail at 10 A.M.
5th.—Brilliant early, but haze and thin cloud from 9 A.M.
6th.—Brilliant morning; a little cloud in afternoon; bright night.
7th.—Overcast morning; frequently sunny in afternoon. Lunar halo at night.
8th.—Warm, with bright sunshine throughout.
9th.—Occasional showers in morning, and thunder, lightning, and heavy rain at noon; variable and windy after.

On the whole fine, but rather stormy at the end. Temperature above the average, and 7° above that of the preceding week.—G. J. SYMONS.

DOBBIE & CO.'S

ANNOUNCEMENTS.

DAHLIA PLANTS.

WE ARE NOW BUSY SENDING THESE out to all parts of Britain, and to many continental countries. Those who have not already ordered, and who are desirous of having Dahlias early in bloom, should send in their orders at once. When received (in Neponset paper flower-pots if desired with balls of soil whole), they should be potted into 4-inch pots in nice, rich, open compost, and grown on for two or three weeks in a warm house or frame, afterwards gradually hardened off, and planted out 1st June. This is the way to obtain plants which will begin blooming in July.

We grow the best, and only the best, varieties in all the different sections—

Show and Fancy, True Cactus, Decorative, Pompone, Single, and Single Cactus,

and offer our Selection at the uniform price of

5/- per dozen (in Neponset pots, 5/6), Carriage Paid.
35/- per 100 (in Neponset pots, 35/-), Carriage Paid.

(In not less than 50 varieties).

Buyers wishing to make their own Selections can have Catalogues on application.

THE DAHLIA: Its History and Cultivation.

A HANDBOOK FOR ALL GROWERS.

The *Leeds Mercury* says:—"With the aid of this pretty illustrated volume the cultivation of this superb flower should present no difficulties to anyone."

Price, in stiff paper covers, 1/-; in cloth boards, 1/6; post free.

EARLY FLOWERING CHRYSANTHEMUMS.

Our Collection is one of the Finest Extant.

Fine plants, ready for planting in the open border. Will bloom from July onwards. Our Selection—12 plants for 3/-, 25 for 5/6, 50 for 10/-, 100 for 17/6. Carriage paid. A trial order for these is particularly solicited.

"FLOWERS IN SEASON.—Some glorious bunches of Early-Flowering Chrysanthemums reach us from the Scotch Nursery of Messrs. Dobbie & Co., at Rothesay. They are all very beautiful, and no plea for their cultivation need be urged when they afford such flowers from an open field so late as October 8th."—*Gardener's Chronicle*, October 16th, 1897.

PELARGONIUMS.

Fine Plants. Splendid Value.

12 GRAND SINGLE VARIETIES, post free for 4/6, 6 for 2/6.
12 GRAND DOUBLE VARIETIES, post free for 4/6, 6 for 2/6.
12 SPLENDID REGAL AND SHOW VARIETIES, post free for 6/6, 6 for 3/6.

12 SCENTED GERANIUMS, lovely cut foliage and delicious perfume, post free for 4/6, 6 for 2/6.

Cuttings of all the above Half-price.

VIOLAS.

"Messrs. Dobbie & Co. stand first in Viola culture."—*Birmingham Daily Gazette*.

FOR EXHIBITION OR FOR CUT FLOWERS.—We offer one dozen of the Very Finest Violas, our selection, including several recently introduced varieties, for 2/6, post free.

50 in 25 of the very Finest Varieties, 10/-, carriage paid.

100 in 50 of the very Finest Varieties, 20/- carriage paid.

This last lot will put any one at once into the possession of a really superior and complete collection of Violas.

FOR BEDDING.—100 in 12 varieties for 12/6, carriage paid.

DOBBIE'S

FERTILIZING COMPOUND

A High-class Artificial Manure for all Horticultural Purposes.

SAMPLE TIN BOX, POST FREE, SIXPENCE.

DOBBIE & CO.,

ROYAL FLORISTS,
ROTHESAY.

No. 930.—VOL. XXXVI., THIRD SERIES.

STOVE & GREENHOUSE PLANTS, FERNS, &c.

Buyers of these are invited to inspect one of the largest stocks in the Kingdom of well-grown, clean, healthy plants in various sizes and immense variety at Oldfield Nurseries, Altrincham. Broadheath Station, L. & N.W. Ry.; West Timperley C. Lines Ry., and Altrincham; M. S. J. & A. Ry., are all within easy distance of the Nurseries, and all afford ready access from Liverpool, Chester, Warrington, Preston, Manchester, Stockport, Crewe, &c. The advantage of seeing plants before buying is obvious, but those who cannot pay a visit can have the fullest information on any matter of prices, sizes, &c., on application. Catalogues, with Description, Prices, Cultural Hints, Post Free.

CLIBRANS, ALTRINCHAM & MANCHESTER.

PLANT NOW

Carnations, Pansies, Phloxes, &c.

NEW CATALOGUE (No. 503) of HERBACEOUS and ALPINE PLANTS, also of FLORIST FLOWERS, &c., Now Ready, and will be sent post free on application.

DICKSONS Nurseries CHESTER

LONDON FERN NURSERIES,

LOUGHBOROUGH JUNCTION, LONDON, S.W.—Ferns, large and small, in variety; Aralias, Grevilleas, Cyperus, Ficus, Ericas, Palms, Dracenas, Aspidistras, Hydrangeas, Pelargoniums, Fuchsias, Marguerites, Crotons, &c. Trade, send for Wholesale List. Special List for Amateurs, send for one.—J. E. SMITH.

ORCHIDS FOR SALE.—About 200 Established Plants, in fine condition, including Cattleyas of the best varieties; Dendrobiums, fine specimens of Nobile and other sorts; Cypripediums in variety, Lælias, Phajns, Stanhopeas, Oncidiums, and others; also a few Stove Plants, Palms, and large Specimen Ferns. Can be seen on application to Mr. ROBERT BURRELL, Westley Hall, Bury St. Edmunds.

TREE TOMATO.—Grand New Hybrid, no stakes required. Dwarf and easy to grow, heavy cropper, fine fruit. Good for open-air culture. (See illustration, *Amateur Gardening*, April 16th.) Plants, 3 for 2/-, 6 for 3/-, or 5/- per dozen, free for cash.—R. HOLMES, Norwich.

ASPARAGUS.—This delicious vegetable does not require half the expense usually incurred. For simple instructions see SEED LIST, free on application. Strong roots from 2/6 per 100.—RICHARD SMITH & CO., Nurserymen and Seed Merchants, Worcester.

IMPORTANT TO MUSHROOM GROWERS.—CUTHBERT'S SPECIALITE MUSHROOM SPAWN. Always alike; most productive. Hundreds of Testimonials. Per Bushel, 5/-.—R. & G. CUTHBERT, Seed, Bulb, and Plant Merchants, Southgate, N. Established 1797.

100,000 BEGONIA TUBERS.—Large, erect flowering. Single, 12 for 2/3; 100, 16/-. Double, 12 for 2/6; 100, 17/-. SEND FOR LIST, FREE.—JOHN WELLS, Begonia Nursery, Ryarsh, Malling, Kent.

TOBACCO POWDER.—Corry's, Fowler's, or Pooley's. Introduced in 1866, and manufactured at our Bonded Stores, Shad Thames, S.E., free of duty. Tins of increased size, 1/-, 2/6, 5/- each. TOBACCO JUICE, 42 ozs. to the gall. In bottles, 1 pint, 1/-; 1 quart, 1/9; 1/2 gall., 2/6; 1 gall., 4/-, including bottles.—CORRY & CO., Ltd., Finsbury Street, London, and all Seedsmen and Florists.

HEATING APPARATUS.—Medals 1875 and 1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2/6; post free, 2/10.—JONES and ATTWOOD, Stourbridge.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—HIRST, BROOKE & HIRST, Ltd., Leeds.

ALL WHO WISH GRAND RESULTS should use THOMSON'S IMPROVED VINE, PLANT and VEGETABLE MANURE. This Valuable Manure is yearly growing in public favour. Can be had of all Nursery and Seedsmen, or direct from the makers, WM. THOMSON and SONS, Ltd., Tweed Vineyard, Clovenfords, Galashiels, N.B. Price Lists and Testimonials on Application. 1 cwt. and upwards Carriage Paid to all stations in Britain and Ireland. London Agent—Mr. J. GEORGE, 14, Redgrave Road, Putney. Agent for Channel Islands—Mr. J. H. PARSONS, Market Place, Guernsey. Also THOMSON'S SPECIAL CHRYSANTHEMUM MANURE. 1/2 cwt. Carriage Paid to all stations in Britain and Ireland.

Journal of Horticulture.

THURSDAY, APRIL 21, 1898.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St. London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

IXORAS FOR EXHIBITION.

IXORAS are in the front rank of exhibition plants, and are of considerable value for affording supplies of choice cut flowers throughout the greater part of the year, always provided in each case that the plants are well grown. Many of those sickly-looking bug-infested objects to be seen occasionally would be more in their place on the rubbish heap or in a bonfire, but because they are Ixoras the growers seem to think that they must be preserved, unsightly though they are. Let me, however, warn inexperienced exhibitors that judges invariably appraise Ixoras at their true value; and plants ought, therefore, to be shown in a presentable condition. It is not merely as specimens that Ixoras are of value to the exhibitor. Neat little plants with few or many good trusses of flower are most effective in groups, supplying colours not forthcoming in other flowers, while cut trusses are equally appreciated in stands of stove and greenhouse flowers.

If limited to a single species or variety of Ixora I would unhesitatingly choose *I. coccinea superba*, a variety of free, even vigorous, growth, and which produces large, compact heads of well-formed bright red flowers. *I. Williamsi* also possesses a good constitution, and well-grown plants give a profusion of large heads of reddish salmon flowers. *I. Pilgrimi*, raised from *I. Williamsi*, possesses the same good characteristics, while the flowers, bright orange scarlet in colour, are produced in extra large trusses. *I. Colei*, flowers white, in medium-sized trusses, is also a desirable variety, and not difficult to cultivate. *I. Duffi*, the finest of all the Ixoras, produces huge trusses of crimson red flowers, and *I. salicifolia*, also to be seen occasionally, require more than ordinarily skilful culture, but pay well for the trouble taken with them.

Ixoras can be kept in good health and a serviceable condition for several years, but once these old plants become unhealthy it is very difficult to restore them to a proper state. It is well, therefore, to have a series of young plants coming on to take the place of the worn-out old ones. They are not difficult to propagate. The best time

No. 2586.—VOL. XCVIII., OLD SERIES.

to root cuttings is during March and April. Short-jointed shoots of the preceding year's growth, and about 4 inches long, should be selected, cutting these below a joint, but not trimming off the lower leaves and buds, as it is from these buds below the surface that strong growths ought to start during the first two years or so. Insert the cuttings singly in small pots filled with sandy peat, plunge them in bottom heat of 75° to 80°, and keep close till well rooted, this occupying about one month. Give an early shift into 4-inch pots, and it is just possible that a second small shift may be given safely the same season, but overpotting at any period of the plant's life is a great mistake, which has led to many partial or complete failures.

I have been fairly successful in growing *Ixoras* in what may be termed loamy compost, but, all things considered, favour the orthodox mixture of two parts good fibrous peat in a lumpy state for the larger shifts, one part each of leaf soil and fibrous loam of a light character, adding silver sand and crushed charcoal freely. If good fibrous loam is not available, no loam should be included in the compost. It need hardly be added that only clean well-drained pots ought to be used, and that the potting should be done somewhat firmly. No shifts ought to be given later than September.

Ixoras thrive in strong heat, ranging say from 75° to 85° during the spring and summer months, resting them during the winter in a temperature of 60° to 65°. They ought to be shaded from bright sun, and to have the benefit of abundance of moisture in the atmosphere, also frequent forcible syringings with tepid water. If young plants are topped they will not flower till very late in the season, if at all; but topping naturally helps to make them bushy, and to force up strong shoots from below the soil. While resting in a light position, apply enough water to keep the wood plump and the leaves from shrivelling, and do what pruning is necessary in November. *Ixoras* will stand moderately hard pruning, and are best kept in good form by the knife rather than by training.

Late in February or early in March, when the temperature can be raised without the expenditure of much fire heat, start the plants into active growth. They will thrive best if arranged on, rather than plunged in, a hotbed of leaves, or leaves and manure. Repot before much progress has been made, in the case of the older specimens removing much of the soil unoccupied by roots, and so reducing the balls as to admit of repotting in sizes only a little, if any, larger than they were previously in, not forgetting to allow space for ample drainage. Plants required to flower late in July or early in August ought to be started extra early, and in the case of *I. coccinea superba* there must be no topping of the young shoots, or the flowering period will be too late.

The other varieties recommended should not be topped later than March. *I. Duffi* flowers on the strong well-matured growths formed during the year previous, and plants cannot be depended upon, therefore, to flower every season. The way out of the difficulty is to have two sets of plants. When *Ixoras* are first repotted water very carefully, so as to avoid souring the new soil before it can be well occupied by roots; but when roots are abundant copious supplies of water are needed. Plants strongly rooted are also benefited by liquid manure, but this must not be very strong. That formed by placing sheep's droppings in coarse bags, and steeping these in tubs of water for several days, is recommended; and it is safe and good practice to apply Standen's manure sparingly about twice during the season.

Many failures with *Ixoras* may be traced to attacks of insect pests. The plants would appear to be peculiarly liable to be infested by mealy bug, and once overrun by this pest are very difficult to clean. With Mr. J. Cypher, the noted exhibitor, the remedy is Fir-tree oil, diluted and applied as advised by the vendors, coupled with frequent forcible syringings with tepid water, clear soot water also doing good. A close look-out should be kept for any stray insects that may survive the remedies suggested, destroying these saving much labour subsequently. It ought, perhaps, to be added that all plants should be laid on their sides when heavily syringed with either insecticide or clear water, and every precaution taken to keep the soil in the pots from being saturated with it. Both thrips and green fly used at one

time to be troublesome, but since the introduction of nicotine vaporisers their eradication is both safe and simple.

Keeping the plants well supplied with water at the roots during the hottest part of the year, sheltering them from currents of dry air, and syringing freely and often, are preventives of red spider. Scale can be got rid of in the same way as mealy bug, and it only remains to be added that any comparatively violent remedies for destroying either of these pests should be applied while the plants are at rest.—
GROWER AND EXHIBITOR.

PROFITABLE FRUIT GROWING.

(Continued from page 323.)

To show the difference there is in the stuff some men are made of, I may instance the case of two men I knew well, who both started for themselves after serving about the same time in the same market establishment. One took a piece of old pasture land in a good locality, near a good market. He had a Tomato house built 100 feet long, at a cost of some £90 or so. He laid out a large portion of his ground in Strawberries and small bush fruit, simply digging down the turf and planting. The consequence was that weeds and foul grass after the first year got the upper hand. He had a good crop of Tomatoes the first year, as almost anyone will have on fresh soil. The second was not so good, and the third year was a complete failure. He had to clear out last year. His whole stock, including the Tomato house, did not bring much more than £30. This was a square man trying to fill a round hole.

The other man—he, too, made Tomatoes his mainstay the first year. He started in an old market garden entirely overrun with weeds and rubbish, as it was not paying the party who had it previously. He entered at a November term, and what he did the first year I leave him to tell in his own words:—"Dear Sir,—I send you the particulars you asked for; you can use them as you think fit. I will begin with the glass. One house is a lean-to, 200 feet long and 14 feet wide, with three rows of pipes, two flows and one return. The other is span-roofed, 220 feet long and 20 wide, with four rows of pipes, two flows and two return. Two new flued saddle boilers 3 feet long. The pipes, boiler, bends, valves, and fittings complete cost us £62. The glass, which is 21 oz., 18 inches by 24, cost £40. The wood, second quality red pine, also cost £40, the whole coming to £142. The extras, such as bricks, lime, paint and putty, came to £20. Our labour for erecting the two houses at the rate we were working at is twenty weeks at £1 per week—£20. Total for material and building, £182, or 8s. 8d. per foot run. We planted 2000 Tomatoes and gathered 6 tons of fruit, or an average of 6½ lbs. per plant. The average price was 6d. per lb., which made £336, or £154 more than it cost to erect the houses; and we hope to do better this year, as we are at the present time quite two months ahead with our work to last year. I think we have done fairly well, coming into the place and not a vestige on it of any good, but plenty of weeds and dirt. We knocked over £400 out of it, and it is not 2 acres in extent." I may tell you that I have seen the two houses referred to, and they are as good and substantial as any of their kind in the country. This was the right man in the right place, with brains in his head, and not more than one thumb on each hand.

I have said more on this point than I intended, but I am anxious to emphasise the fact—for it is the very root and foundation of success—that unless you are possessed of ability, energy, perseverance, and a love for your work, all the knowledge and experience in the world will avail you little. Some men, though they had served their time in the hanging gardens of Babylon, and been in all the best places in the world ever since—and to hear some of them talk you would think they had—if thrown on their own resources to make a living would make a very poor one indeed. Before leaving this part of my subject, I should like to say a word or two to the young men.

I say, first of all have an aim. Get your whole heart into your work. You will find how much easier and pleasanter your duties will become. Read everything you can lay hold of bearing on your business. Think for yourselves. Try and get to the bottom of things. Begin early to practise your brain in scheming and planning the easiest, the quickest, and the cheapest way to do a given piece of work. Have a method in everything you do, for method is the hinge of business. Try as far as possible to have certain jobs finished at certain times, and that at meal times and stopping times. It makes a great difference in the amount of work gone through in a week if a fresh job, or fresh part of a job, is begun each starting time of a day. Never look in a careless, indifferent way at a tradesman, such as a joiner or mason, doing a job, but "glower" at him and his work. Take note of how it is done. The day may come when you will wish you had paid more attention. A knowledge of other trades is a great service to a head gardener, and doubly so to a market gardener. Not

only should you know the theory of a few of the most useful and common, but if you are able to turn your hand in a creditable way at them you will find it to your advantage; besides, it is a most interesting and instructive pastime. You have met, perhaps, as I have, men who were possessed of as much mechanical genius as would enable them to make a creditable tooth-pick, but no more. I have found in my experience that those who were most "knacky" with their hands were always the best and most useful workmen.

Have an ambition to excel. Remember that you need not be a born genius to be successful in your business. The greater part, if not the whole of success, is made up of strict and intelligent attention to every little detail connected with the thing you wish to accomplish. Did you ever calculate the difference there is between the amount of heat lost or gained by a right or wrong system of ventilating a vinery or other house, where the object should be to make the most of the heat from the sun while it shines? A careless man will open his ventilators when the sun shines, and shut them when it does not, and as often as not he will do the latter five, ten, or fifteen minutes after the sun has gone off the house, and in this time the temperature will have fallen 20°. This may happen half a dozen times a day. Averaging a loss of 20° for four months, you have a total of 2240° of the best and most natural heat you can have for the life and health of plants. You cannot afford to neglect the smallest detail. Pay as much attention to the airing of a cold frame, and do it on the same principle as you do a grand vinery. The results will astonish you, and you will be training yourselves into a system of thoughtful attention and methodical practice which alone will make you clever men and good workmen. Good men, remember, are scarce. The supply is not equal to the demand. I consider a really good and capable gardener, whether head or under, receives only about half the remuneration he should, for the care and responsibility, the intelligent thought, and ingenious resource he has to put into his business is ten times more than a mason, joiner, or like tradesman has to do to earn his £2 per week. If commercial gardening is not already, I think it soon will be the most important branch of our vocation. Plenty of openings there are for able brains and clever hands. Their ability will meet with its due reward.

We will next consider a few general principles which are the root and foundation of all successful fruit cultivation. Outside fruit trees do not receive the attention they deserve. A crop of Grapes or Tomatoes will be either fed each time they are watered or at least have five or six dressings of some fertiliser during the growing season. Did you ever hear of an orchard or bush fruits getting this attention in the way of feeding? If they have some manure dug amongst the roots or a top-dressing once a year it is about all they get, and if they do not fruit well the weather gets the blame. I do not say that more feeding would make all our trees and bushes as they are at present more fruitful. No; it would most likely do the very opposite to many, and make them worse than they are, for I believe there are more trees unfruitful through being too gross than through starvation. But have them planted in the right rooting medium and you will have the right fruiting wood; then give ten times more feeding than what is given now, and it will repay you.

The right rooting medium! That brings me to the most important point—the A B C of successful fruit culture, for unless the growth made by a fruit tree—either out of doors or under glass, from a Vine to a Gooseberry—is of the right material, and made in the right way, you will either get inferior fruit or no fruit at all. This perfect fruitful growth cannot be made without an abundance of small fibrous feeding roots. These small fibrous roots cannot be made unless the rooting medium, or in other words the soil, is in the right condition for their formation; three essentials of which are warmth, moisture, and a degree of firmness, without which wood roots and not fibres will be formed.

I leave out, at present, the consideration of the soil containing the proper ingredients essential to the formation of fruitful growth—for you could have this in all due proportion, and still have unsatisfactory fruit, or none at all. I think I am safe in saying that nearly all the failures or partial failures in Grape and Tomato growing, and in many cases hardy fruit growing, could be traced to loose, or too rich a root run, or both. It is very interesting to study the analogy there is between the animal and the vegetable kingdom, how the same law operates for the same end in both. To get a horse into the best possible condition for hard and trying work, we do not feed him on soft sloppy food to make him fat and sleek, like an unfruitful Apple or Pear tree, with its gross shoots over a yard long. The athlete is neither soft, fat, nor flabby. Neither should be the wood of any fruit tree. I do not think there is sufficient attention given to this matter of firm fruit tree borders. A firm border will not suffer from drought to the extent a loose one will. It will not get wet, consequently will be warmer. It acts as a check on the formation of strong wood roots. Every care and attention should be given when making borders, or preparing ground for fruit trees. Every few inches of soil as it is put on should

be well firmed—not merely treading the top after the job is done to make it look firm.

In reference to the many mixtures and fertilisers we see recommended to add to the soil, I would say, if you have good ordinary fresh loam, the less you add to it the better, and never, unless under most exceptional circumstances, mix farmyard manure with the soil for fruit trees. When I say loam, I do not mean the top few inches of turf taken from old pasture. Wonderful results are no doubt got, and sensational samples of fruit seen from the use of this, but for lasting qualities and profitable results, the whole soil, as well as the turf, should be taken, stones and all. There is not only a mysterious something in fresh loam which suits the requirements of a fruit-bearing tree better than any artificial compound that can be added, but the firmness and solidity of the soil in its natural state forms the best medium for the production of the right kind of roots to make fruitful growth, and I think better results would be secured if the fruit trees were, so to speak, oftener brought to the soil than the soil to the trees.

I have of late had a few opportunities of noting the beneficial results of Vine roots finding their way into fresh original soil. And now, when we have an outside Vine border to make—which we do by simply deepening the soil, as it is very shallow, after the subsoil, which I may state is hard red till, is deepened the required depth, the soil is put back with more added to it on the top. This we like done at least one year before we expect the roots to enter it. This gives it time to get firm by natural agencies.

As this subject of the right rooting medium is in my opinion at the foundation of all success, it is my excuse for dwelling so long upon it. If the foundation is wrong, the whole superstructure will be faulty and bad. The details of pruning and training are of little importance compared to this; for if the roots are right the wood will be right, and little or no pruning will be required; pruning and restricting a gross growing tree only aggravates the evil. If it were allowed to extend it might right itself through time. I have seen—and in this country—a man do all the pruning that was necessary to several breaks and borders of Gooseberries in a little over two hours time, and I have seen these same bushes annually supported by long runners of wood to prevent the branches breaking off with weight of fruit, and this year after year. We have a row of Winham's Industry Gooseberry which has carried enormous crops for the last four seasons, which have had to be supported in the same way, and which have never had a knife on them since they were planted young bushes till this winter. Gooseberries as a rule are pruned far too much. I think, on this subject, there is more rule of thumb practice shown than I thought the present generation of gardeners capable of.

—D. BUCHANAN.

(To be continued.)

GLOBE ARTICHOKE.

THERE are two varieties of this much-prized vegetable in cultivation, both of which are indigenous to the countries bounding the Mediterranean. This being a more genial climate than our own, the plants are benefited by some kind of protection during the winter months, and although they will not suffer to any extent if left unprotected in the majority of our seasons, it will be found advantageous to be prepared in this respect, for in winters of extraordinary severity the Globe Artichoke has been quite destroyed.

The soil best suited to this plant is one abounding in moisture, such as a good deep loam impregnated with a large portion of saline matter. In dry sandy soils the produce will be inferior—indeed, scarcely worth the time bestowed in cultivation. The position allotted to the plants should be an open one, and well away from the influence of large trees. As regards manure, seaweed has the precedence; but as this is not always procurable, a good dressing of well-decayed stable manure should be applied early in the spring. This may be dug in together with the rough litter and leaves used for winter protection. A sprinkling of common salt will benefit the plants considerably, and should be applied in the same proportion and at the same time as is usually given to Asparagus beds. In the event of seaweed being procurable, this latter, of course, will not be needed.

In preparing the ground for new plantations, it should be trenched to the depth of 2 feet, and be well enriched with manure and wood ashes. It is also an excellent plan to mulch the beds well after planting to retain the moisture, and this can remain on the whole summer with advantage. The usual way is to plant suckers from the old stools, and this is most expeditious, and is best performed early in April, selecting such as have abundance of fibrous roots. The rows should be 5 feet apart, and 4 feet ought to be allowed from plant to plant. Water may be applied when this operation is completed, and then a mulching can be put on. The only attention required during the summer is the frequent use of the Dutch hoe, and with occasional waterings in very dry weather. The plants will produce a succession of heads from July to the end of August the first year after planting, and they will continue to increase in productiveness for a period of four or five years, when a new plantation should be made. By planting afresh at the intervals named, it will be noted that the edible part will be much superior both in size and quality to heads obtained from old plants.—H. T. M., *Stoneleigh*.

APRIL FLOWERS.

TYPICAL April weather, with its smiles and tears, brings with it many flowers, and paves the way for the wealth of May. The Primrose shines in shady nooks; on the heath the Furze is aglow with gold; the Blackthorn is wreathed in white, and the Celandine is bright with its stars of gold. In the wood, the orchard, the shrubbery, and the garden the beauties of the outer world are brought closer together, and our eyes are gladdened by the sight of their flowers. The theme is wide, but we must curb ourselves and look more narrowly into the flowers of the time. Hardy flowers themselves branch out into many families, and we are apt to become entangled in the delights of a few genera to the neglect of others, unless we are wary, and seek to extricate ourselves in time. We might well dally with the Daffodils, coquet with the Fritillaries, or spend all our time among the Primulas or Violas, so full of beauty in the youth of the year.

If we dally long with the first, we may find ourselves tempted to tell of the rarer flowers sacred to the gardens of the wealthy, and to say naught of the gracious beauty of those within the reach of the many, and which may be planted singly or in generous clumps, as the purse or fancy of the gardener may allow. Enthusiasts possessed of means enough can purchase Monarch, Weardale Perfection, or other Daffodils which, as it were, bear the blue ribbon for the time, but others may find equal enjoyment in admiring Emperor, Empress, and the many other Narcissi, full of beauty, and within the reach of prince and peasant. Others may tell of the newer and rarer varieties, and many of these have been figured in the Journal. Their fascinations are great, but the clumps of the commoner kinds appeal to almost all as they float gently to and fro in the April winds. One only shall be mentioned now, and that because of its earliness among the section—that of the *Incomparabilis* Daffodils—to which it belongs. This is Queen Bess, with large light yellow expanded cup, and pure white perianth segments. Beautiful it is, and so cheap that he is poor indeed who cannot include it among his garden treasures.

Queer things are the Fritillaries to those who know them not, and quaint do they seem always to those who know them best. The majority of us have to content ourselves with seeing Gerard's "Ginnie-hen flower" in our gardens instead of by the grassy meadows of the Thames. In moist nook or on rocky bank they please us with their drooping bells, but their beauty is best seen when their flowers are turned up by the hand and their interior viewed. If *Fritillaria meleagris* is easily grown as much may be said for *F. acmopetala*, *F. Thunbergi*, *F. pallidiflora*, and several others. Less confident we may well be if we plant *F. recurva*, *F. aurea*, *F. Moggridgei*, and *F. Burnati*. We may grow them for a year or two, but in many gardens they are difficult to keep beyond that time.

The Primulas have more worshippers at their shrine. There is no prettier sight in our British sylvan scenes than a "mossy bank bedight" with the starry flowers of our native Primrose. Much of the beauty of our gardens is due to the varieties which have sprung from this pale-flowered mother. Crimson, scarlets, purples, pinks, lilacs, deep yellows, cream coloured, pure whites, and now wonderfully good blues proclaim the power of cultivation to influence for change. Clustered Polyanthus, Oxlips, and Cowslips are speaking witnesses of the charms of the Primula in gardens many, and of all sizes. And what of the Auriculas? They, with others of the genus, will soon hold court at the Drill Hall, for lack of a more seemly palace, and though we shall not be there we can think of these flowers and their followers. In "Auriculas: A Garden Fancy" Mr. Baildon tells of them in words one would fain quote were it not that space fails. These have, worthily, their devotees, and with them those who delight in the less grown species will admire their own favourites. *Primula marginata*, *P. denticulata*, with its variety *cashmeriana*, *P. Steini*, *P. viscosa*, *P. ciliata*, *P. carniolica*, *P. Dinyana*—these, and many more, have claims on our admiration, with their flowers of many hues and shades. In the border or the rock garden they may share our affections with others of the race.

The earlier Violas have begun to come; but who can say he is able to keep abreast of the host of varieties now open to seek a place in our gardens? Their name is legion, and still they come—white and yellow, blue and purple, lilac, brown, pink, striped, spotted, rayless and rayed, large flowered and small. Very beautiful they are, and we cannot spare them, though they grow beside and eclipse the little wildings from our own or other lands.

But a paragraph remains for a glance at other flowers in bloom. The early Rhododendrons are in blow. *Prunus Pissardi*—the earlier flowers stolen from us by the frost—is again wreathed over its branches. Dog's Tooth Violets, such as *Erythronium revolutum*, *E. citrinum*, and others, turn back their segments and please us by their pretty flowers. Early Saxifrages, Aubrietias, Drabas, Androsaces, and other rock-garden plants brighten the mounds and slopes they occupy. There are yet Glories of the Snow, Hepaticas, *Ornithogalum ciliatum*—an early bloomer—Scillas, Anemones, from the great red,

blue, white, and parti-coloured *A. coronaria* to the simple varieties of the Wood Anemone and that from the Apennines.

As we see all the beauty of the time we recognise how aptly one of our living poets changes his expressive words from "girlish laughter" and "girlish tears" to "golden laughter" and "golden tears." Golden, indeed, are these moods of April—treasure-laden to those longing for the summer days.—S. ARNOTT.

SYRINGING PLANTS.

THE time of the year has arrived when the value of syringing plants growing under glass as an aid to high culture can scarcely be over-estimated. At one time I was rather dubious about syringing many kinds of plants which I have found out since are greatly benefited by the practice. It may be that modern houses, which are so lightly built, may have something to do with the change of practice. I think they have, for in houses of the old type the evaporation from the leaves of plants must have been very slow compared with the rate in which it goes on in the case of plants growing in modern houses, which now seem to have reached a point in regard to lightness of construction beyond which it is not desirable to go.

The point which now requires more general consideration is that of providing adequate means of ventilation. Houses put up by firms of repute are usually well arranged in this respect, but when they are built by men who are not specialists, very haphazard methods of providing ventilation are often resorted to. This is surely false economy, because there is nothing that can mar so quickly the prospect of any crop growing under glass as insufficient ventilating at a critical time. When houses cannot be given the requisite amount of air, there are two ways of preventing the vegetation growing in them from being greatly injured by such circumstances. I have written there are two ways, but in reality they may be considered as one, as they should be practised in conjunction. I refer to shading and syringing.

The present day method of growing Cucumbers illustrates my point. Instead of making the airing of such houses a source of perpetual trouble we now keep them saturated with moisture and lightly shaded in bright weather, and thus secure quickly grown and tender fruits at a minimum of cost in labour and fuel. This principle, I think, may be partially applied to plants growing in what should be cool houses, but which are not so in bright weather owing to the little amount of ventilation which can be given. A slight shade given to the roof, and a thorough syringing to the plants, will keep them healthy and vigorous.

The popular Marguerite when grown in cold pits on an ash bottom will often thrive well without syringing, but place them in light houses of modern construction, attend to them well in other respects, but do not syringe; then very unsatisfactory results follow, for the plants are continually infested with green fly, and almost invariably with the dreaded maggot. A thorough syringing twice daily would have brought about results infinitely more satisfactory. In fact, the white Marguerite enjoys syringing as much as do the incurved and Japanese Chrysanthemums. Rose trees in cool houses, which are now rapidly coming into flower, enjoy their daily syringing, and soon show ill effects when it is withheld. The water thus applied not only helps to keep both foliage and flowers clean, but also to promote rapid growth, and swell flower buds to a large size.

Ivy-leaved Pelargoniums again, especially when growing in ill-ventilated houses, delight in receiving daily syringings; the growth then comes freely, and insect pests are kept down. Even Zonal Pelargoniums in the early stages of growth after being repotted are benefited by the same practice, although it is in their case not wise to continue it when the plants are growing freely, as it is apt to induce strong sappy growth. Dracenas, Palms, Coleus, Fuchsias, Callas, Azaleas, Aralias, Crotons, and indeed almost all fine-foliaged stove and greenhouse plants, revel in repeated syringings during spring and summer.

A mistake to avoid is to syringe indiscriminately alike in all weathers. During dull or wet periods only an occasional syringing should be given, then with a sudden change to bright weather, the plants feel the benefit of a return to the practice of receiving copious "artificial showers." Fortunately, such showers are more under control than natural ones, as we can give them an upward force, so directed as to wet the under as well as the upper surface of the leaves, and thus disturb in their hiding place the many insects which seem to feel secure on the under sides of leaves. Although it is not generally admitted that leaves absorb moisture to any great extent, there can be no doubt that growth in nearly all kinds of vegetation is greatly promoted by showers of natural or artificial rain. One reason for this is that evaporation is greatly lessened; but another, which is often overlooked, is that the moisture also conveys gases to the leaves which they have the power of absorbing through their pores, and thus materially assisting in the formation of growth.—A WORKER.

EULOPHIELLA PEETERSIANA.

THIS is a superb Orchid, and is far superior to the now comparatively well known *Eulophiella Elisabethæ*. It was shown by Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, where it is flowering for the first time in this country. The spike is of great length, and carries upwards of a score of expanded flowers and buds. The individual flowers are of a rich rose, with a suffusion of purple over the sepals and petals and the front lobe of the lip. The inner portion of the lip and the throat are white, the latter having veins of crimson-rose, while the colour of the side lobes is the same as that of the sepals. The Orchid Committee awarded a first-class certificate for this plant, of which a flower is depicted in the woodcut (fig. 66).

EPIDENDRUM BICORNUTUM.

IN the Orchid section of the last Drill Hall exhibition one of the most interesting exhibits was the group of *Epidendrum* (*Diacrium*) *bicornutum* staged by Mr. F. J. Thorne, gardener to Major Joicey of Sunningdale. As every Orchid grower knows, this is one of those "miffy" plants with which few people have any success, and it was therefore a surprise to many to see the healthy plants with their rich green leaves and grand spikes of lovely flowers. As an eminent authority on Orchids said to me, "They are a triumph of cultural skill." I, for one, wish I could attain similar results, as it is an Orchid that everyone admires.

Messrs. J. Veitch & Sons in their "Orchid Manual" say, "This Orchid has frequently proved disappointing, a circumstance partly due, we have no doubt, to the difficulty of importing it in sound condition. Its hollow stems are inhabited by small ants, which find ingress through a cleft at the base, that invariably occurs in the new growths under cultivation, and probably also in a wild state; they are prone to decay from within, and frequently crack during transmission, and in however small a degree they may be so affected the plants never get well established in the glass houses of this country, and die in the course of two or three years after importation. With thoroughly sound plants the case is more hopeful. Teak baskets are usually preferred, and as they require but a very small quantity of compost a good drainage can always be secured. The compost should consist of the usual proportions of sphagnum and fibrous peat, with which many cultivators mix some pieces of charcoal. The habitat of the species indicates a high temperature and moist atmosphere, and these conditions are therefore necessary, especially while the plant is growing." So far as possible I have followed the suggestions embodied in this note, but have always failed to reach success. Perhaps Mr. Thorne would oblige with a few hints as to treatment in the *Journal of Horticulture*, as I feel sure they would be appreciated by many besides myself.—KENTISH MAN.

[We have received a photograph of Mr. Thorne's best plant, which shows it to be carrying six strong spikes, but as one was broken off prior to the picture being taken, the plant produced seven spikes. This is such an excellent example of cultural skill that we much regret the photo being unsuitable for reproduction. We heartily congratulate Mr. Thorne on his success with this and other Orchids, and trust that he will find time to render assistance to our Kentish correspondent. *E. bicornutum* was figured in the *Journal of Horticulture* for July 9th, 1896, page 29.]

THE STRUCTURE AND CLASSIFICATION OF MUSHROOMS.

WHATEVER may be the cause of the present popular interest in Mushrooms, it is evident not only to botanists, but to casual readers of the monthly periodicals and of the daily press, that within a few years this interest has grown largely, and that it is spreading widely. Its manifestations are various and unmistakeable; but most of them have taken the form of demands for information and of the responses of those who have been willing to give it.

Most of the numerous articles that have appeared have been concerned with showing the difference between edible and poisonous kinds of Mushrooms (or Toadstools, which are the same thing). There are, however, many persons who wish to know something about Mushrooms as plants, and perhaps to engage in limited studies concerning them. These people generally lack a knowledge of the elementary facts concerning structure and classification that would make easy an attack upon the literature of the subject. To such would-be students of a small part of the field of mycology this lecture is addressed in the hope that it may be of some assistance.

At the outset it will be well to come to an understanding as to the term "Mushroom" itself. In everyday language it usually means the sort of fleshy fungus that is good to eat, and particularly—to some people only—the common pasture kind. A "Toadstool," on the other hand, means something poisonous, or at least to be avoided. As a matter of fact, no distinction can be made between the two terms, though the term Toadstool is more comprehensive, for it may be used to include the common pasture Mushroom and all other fungi whose form is in general the same.

If we look at a common Mushroom of the pasture or the market, we see that it may be easily divided into two parts—an upright stalk, called the "stipe," and a flat, expanded portion, the "cap" or "pileus." Attached to the under side of the cap are membranous plates, the "gills," or "laminae," radiating from the top of the stipe to the edge of the pileus. The upper part of the gills is attached to the lower surface of the cap, and their lower edges, which are usually very thin and rather sharp, hang free. In the Mushroom that we are examining there is a space between the crowded inner ends of the gills and the top of the stem.

In other kinds of Mushrooms we may find the same condition of things, or it may be that the gills reach the stem and are attached to it, or even run down upon it as ridges, which in some cases end abruptly and in others are gradually reduced to mere lines. Upon the gills are borne in countless numbers the spores—exceedingly minute bodies, which, as it is their office to germinate and grow into new Mushroom plants,

FIG. 66.—EULOPHIELLA PEETERSIANA.

may be roughly compared to seeds. The Mushroom, in fact, as we see it, is nothing but a contrivance for the production and dissemination of the spores. The arrangement of the gills gives an enormous spore-bearing surface, whence the spores are carried by the wind or by insects, or drop to the ground below. If the cap of a fully grown Mushroom be cut from the stem and laid, gills downward, on paper under a tumbler or other cover to keep draughts away, there will be found on the paper after a few hours—sometimes in a very short time—a layer of spores, making a negative print of the gills. In the common Mushroom this print will be of a dark brown—almost a purple brown—the colour, it will be noticed, of the gills at maturity, for the gills usually take the colour of the spores.

Stem, cap, and gills are characteristic parts of most of the fungi commonly called Mushrooms or Toadstools. There are other structures, however, peculiar to certain groups. These are a "volva," a "ring," and a "veil." The common Mushroom does not possess the volva, or sheath, characteristic of the poisonous *Amanita*, but does show us a ring and veil.

If we look at a young specimen that has not been long above ground and is still in its compact, rounded form, called by Mushroom growers a "button," we shall see no gills on the under side of the cap. Indeed, the Mushroom may sometimes grow to nearly its full height before they are visible. The reason is easy to see, for stretching unbroken from the edge of the unexpanded pileus to the stem is a delicate membrane called the veil. As the pileus expands the veil is torn. Shreds of it, perhaps, cling to the edge of the cap, but most of it remains, encircling the stem and thus forming a ring—a structure the appearance and size of which vary in the different sorts of Mushrooms which possess one.

The structures so far spoken of are easily seen, but there is much more to a Mushroom than this. You have been told that a Mushroom is simply a contrivance for bearing spores. It is thus comparable to the fruit of a flowering plant, which develops and contains the seeds. Where, then, you will ask, is the vegetative part of the plant, the part that absorbs the nourishment and does all the preparatory work of which the growth of the Mushroom itself is the result? In other words, what sort of a plant develops from a spore, and where does it live? If you could follow, as you may under a microscope, the germination of a spore, and the stages of growth which follow, your eyes would give you the answer to

the first part of this question. You would see the minute spherical or ellipsoid bodies, when supplied with the requisite moisture, burst and put forth slender colourless threads called "hyphæ." These in time branch again and again, extending constantly in length to form what is called the "mycelium," or vegetative part of the plant. When such threads are massed together in strands, forming white lacework or cottony bunches, they are easily found in the substratum on which the fungus grows—in rotten wood, for instance, or in a heap of leaves, or other decaying vegetable matter. In such places the mycelium spreads over or permeates the substance from which it draws its food supply. For fungi do not elaborate their food from raw materials as do the plants that have green colouring matter, but are dependant upon other vegetable or animal organisms, either living or dead; that is, they are parasites, or saprophytes.

What is known by Mushroom growers as the "spawn" consists of a dried compressed portion of a Mushroom bed, generally mixed straw and horse droppings, which is permeated by the mycelium. In this condition, in the form of flakes or bricks, it may be transported, and will keep its vitality for months, active growth being for the time arrested. As a rule, then, when Mushroom beds are started, it is the mycelium or spawn which is planted—not the spores. When the proper conditions of warmth and moisture are supplied, growth is resumed, and the threads, lengthening and branching, very soon spread throughout the bed.

It is plain, then, that the Mushroom plant for most of its life is out of sight, and consequently not familiarly known. To this fact are due many erroneous notions about the origin of Mushrooms themselves. When the time has come for the plant to produce its fruit, there form at various points in the mycelium small masses of densely branching interwoven threads, which in time enlarge to an appreciable size. Each of these masses is the beginning of a button, or nascent Mushroom. An examination of buttons in various stages of growth, by means of thin sections brought into the field of a compound microscope, shows pretty clearly the part played by the hyphæ in the Mushroom proper, the substance of which is made up of the compacted and closely interwoven threads and their branches. Along certain radiating lines is formed the framework of the gills, which in the developed Mushroom is called the "trama." Just below the gills an air space appears, the outer wall of which becomes the so-called veil. Lastly, upon the surface of the gills develops a layer of cells standing side by side like the single threads in the pile of velvet or in the surface of an oriental rug.

With these cells we have a special concern. Taken together they form the "hymenium," the spore-producing tissue, which, folded like a fan, is applied to both sides of the gill-plates. A section through a gill shows us this layer. Each one of the club-shaped spore-bearing cells composing it is called a "basidium." Each basidium bears four spores on minute stalks.

Passing some other groups we come to the Morels, Helvellas, and Pezizas. The first two are stalked, and roughly resemble the familiar Agarics; the last are shallow cups or fleshy expansions. A word as to the form of their fructification must suffice. Examination under a microscope of a bit of the outer or upper surface of one of these plants will reveal a mat of crowded slender cylindrical cells covering the surface; none of these cells, however, bears spores on its tip. Instead, some of them—not all—contain spores in their interior. Each is, in fact, a little enclosure, called an "ascus," and if one that is mature be separated from the rest it will readily be seen to contain eight—almost invariably eight—spores. At the proper time these escape from the asci, sometimes suddenly and myriads at once. From the surface of a Peziza, for example, as you look at it, there comes a little puff of smoke as the ejected spores are shot into the air, to be blown away in a tiny cloud. Pezizas, Helvellas, and Morels are some of the "Discomycetes," a class excellently treated for Great Britain by Phillips. Multitudes of fungi besides the Discomycetes have a fructification which consists of asci, and the comprehensive name for all of them is Ascomycetes.

Most of the Mushrooms gathered by the increasing number of fungus hunters, at least by beginners in the study, belong to that class of Basidiomycetes called Hymenomycetes. Among these an Agaric is at once recognised by its gills; a Boletus or Polyporus by its spores; a Hydnum by its tooth-like projections; a Clavaria by its coral-like appearance; and a Tremella by its gelatinous nature. So far identification is a simple matter; but to go farther and decide upon the species requires close study, accurate observation of details of structure, ability to interpret published descriptions, and, most of all, experience.—(Abridged from a Paper read by MR. HOLLIS WEBSTER at a meeting of the Massachusetts Horticultural Society.)

"BLACKS" IN POTATOES.

MR. W. PEA (page 320) in his criticism of my article on this subject (page 276) provides a literary repast. The dish, however, like exhibition Potatoes, seems got up to take the eye. It is dainty, but not satisfying. Having disposed of "blacks" by ignoring them, your versatile correspondent comes to the question in respect of the old sorts *versus* new kinds of Potatoes as regards quality. The Old Ashtop Kidney, Lapstone, and York Regent, with Fluke (to make the quartette) may be described as "ancient," and Webber's White Beauty, Duke of York, Windsor Castle, and Up-to-Date "modern" varieties. What say cultivators prior to the advent of the disease in 1844 of the quality of Potatoes in those days as compared with that of the moderns? The so-called disease-resisting varieties have been produced to such an extent at the expense of quality, that the Royal Horticultural Society's Fruit and Vegetable

Committee always relegate modern sorts to Chiswick for trial, and have the articles cooked before expressing an opinion on their merits or otherwise. Thus quality is placed foremost. When subjected to the crucial test of eating, the most that even Mr. W. Pea can claim for the latest outcome, Up-to-Date, is "respectable flavour." What has become of high quality—the "crack their sides" with mealiness tubers, and if once tasted, never forgotten nutty flavour?

Webber's White Beauty may yield double the crop of the Old Ashtop Kidney, but where is it for earliness?—a matter of consequence as regards price and clearance of the land for an after crop, often of as much or more value than the Potatoes; and then, as regards return, wherein consists the difference in profitable production? Besides, while the Old Ashtop Kidney is quite fit for an epicurean taste, the "Beauty" only finds favour with the masses in towns, who set more store upon quantity than quality. Duke of York represents constitutional vigour and coarseness with negation of high quality. Windsor Castle needs considerable qualification, and I cannot describe its quality as comparable with that of York Regent. As for cropping, York Regent, on warp, has given 25 tons per acre, and a single set 44 lbs. In an 80-acre field, in 1897, Windsor Castle gave a yield of 12½ tons per acre.

Now we come to the "modern" Potato *par excellence*, "the tough hardy constitution, respectable quality, and magnificent cropping and disease-resisting powers." All efforts of late years have been directed to avoiding the Potato disease, yet the all-important Magnum Bonum, the doughty Champion, and the Bruce, all fall before the Raphael Aben-Ezra Potato fungus, only Up-to-Date holding up its head.

Mr. W. Pea says nothing about "blacks" except in connection with "injurious acidity." This betrays some acquaintance with the subject by one who has "been experimenting with Potato manures rather freely during the last few years," and he seems to have been convinced by "one trial" that a muriate manure is the best he has found. The modern experimentalists do not appear to see that by cropping with Potatoes, and applying heavy dressings of manure successively on the same land with but one cereal or other crop in alternate years, the ground may be soured by organic acids as badly as by the use of acid fertilisers, muriate (chloride), or sulphate (sulphuric). "A. D." grasps this fact, hence his "jumping" at lime, which in older times answered well enough, but in these days oftener does the reverse, by burning and blackening crops in consequence of the acid fertilisers applied. How many growers have suffered serious loss by the use of kainit, muriate of potash, and acid phosphate? Who found it out that they were injurious? Or who advised autumn application before growers had found spring dressing sinister? What produced "blacks" formerly does the same now; the one caused by inattention to rotation, and the other by a wholesale and injudicious use of fertilisers.

Just a few words relative to the one-eighth acre experiments. How long have they been conducted on the same land? Mark, there does not exist much change of crop on allotments, and one experiment proves nothing, for a mere changing of fertilisers affects the land wonderfully, while the continuation of the same mixture may result in disaster. The prescription given on page 320 consists of 32 tons per acre of farmyard manure, costing at least £8, and of 10 cwt. per acre of artificial fertiliser in mixture, entailing an outlay of something like £4, which, with labour and planting, amounts to half as much more, or about £18 per acre. Try it as a commercial concern, not once, but over a series of years, and then send the result to the Journal, if, indeed, there be any result left wherewith to procure the needful. Experience has taught me that fertilisers are unprofitable unless they lessen the need of farmyard manure to the benefit of a larger range of crops.

Reverting to "A. D." (page 303), will he kindly say what three present day varieties of Potatoes he has found equal in quality to the old Ashtop Kidney, Fox's Seedling, and Prince Regent? three varieties—early, second early, and late respectively. I find them enumerated in a catalogue issued by Messrs. Thomas & James Backhouse, York (third edition), in 1827.

In 1844 the three varieties—Ashtop Kidney, Lapstone or Haigh's Seedling, and Prince or York Regent—were the standard for early, second early, and late use, and I submit they have not been excelled since for quality. "A. D." can term the dictum "strained" or "untrue," but that will not alter my half-century's experience in arriving at a decision regarding the so-called "up-to-date" varieties—a coarse and poor quality lot. Of several hundred varieties submitted to trial not any that I have grown, or seen grown, have the mealy quality and rich flavour of the fifty years ago varieties.

Not long ago "A. D." made light of the Potato disease causing the "blacks"—a phase of the matter, he now says, demands the "fullest consideration." As to "the denudation of leafage by the fungus" causing the evil, that is a matter of opinion, worth nothing unless backed by experience, and I state it as a fact that Potatoes were infested by "blacks" before the appearance of the Potato fungus in 1844. What caused them then? "A. D." puts forward lime as a cure for "blacks," a mere conjecture—at least, there is no evidence that this element has anything to do with freedom or otherwise of the tubers from discolouration. How does he know that lime has anything to do with the production of starch, or what this has to do with "blacks," or even the Potato fungus? Bordeaux mixture appears the thing for preventing the Potato disease, but your correspondent seems unaware that "a green vigorous condition" is just that in which the fungus delights, and the resultant tubers are discoloured by disease, even if there is up to 10 per cent. of lime in the soil. The proper draining and working of the soil exerts a more wholesome influence. Let "A. D." give the matter fuller consideration.—EXPERIMENTALIST.

WEATHER IN LONDON.—Brilliant weather has prevailed in London during the past seven days. It has been warm on almost every day in the sun, but the wind was sharp on one or two occasions in shady places. The nights continue to be rather chilly, but have not been sufficiently cold to do harm to vegetation.

— WEATHER IN THE NORTH.—With the exception of the 13th, which was very wet, with a high wind from the south, the week ending the morning of Tuesday has been very pleasant, cloud and sunshine alternating, and showers falling occasionally. The temperature has been generally high, although it fell considerably on one or two evenings. That of Tuesday morning was 48°.—B. D., *S. Perthshire*.

— ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, April 26th, in the Drill Hall, James Street, Victoria Street, Westminster, 1 to 5 P.M., when, in addition to the Society's ordinary Show, the National Anemone and Primula Society will hold its annual show. At three o'clock a lecture will be given on "Sweet-scented Leaves versus Fragrant Flowers," by Mr. F. W. Burbidge, M.A., V.M.H.

— HORTICULTURAL CLUB.—The usual monthly dinner and conversazione took place on Tuesday evening, April 12th. Notwithstanding the holidays and the Ghent Exhibition, which drew off several of the members, there was a good attendance. The chair was occupied by Mr. George Paul, V.M.H. The Rev. George Engleheart was the guest of the evening, and gave a very valuable address on Seedling Narcissi, in raising which, as is well known, he has been so successful. He exhibited some of his latest productions, which were greatly admired, and had previously obtained awards of merit at the Drill Hall. An interesting discussion followed, in which many of those present joined.

— MEMORIAL TO MONS. JEAN LINDEN.—We have received a circular from Belgium from which we learn that there is a project on foot in that country to found a memorial of Mons. Jean Linden, the distinguished botanist and horticulturist, whose demise we chronicled some time back. A committee of influential gentlemen has been formed, with Comte O. de Kerchove de Denterghen as President, and Mons. L. Lubbers, Brussels, as Secretary. The Treasurer is Mons. L. Kegeljan, Namur. The appeal is made to every one interested in horticulture, and those who would like particulars should write for them to the Secretary.

— AN IDEAL TENNIS GROUND.—When looking at the illustration given last week of a tennis ground, I could but be thankful I had not been trained in the school of the landscape gardener. For destroying the natural and charming contour of the ground I could not imagine a better example. The excavated court is to me an eyesore. A tennis court should be comparatively near the mansion, and not a quarter of a mile away, as shown in the picture. To enjoy lawn tennis thoroughly the turf, whilst dense, should be soft and springy. Then play upon it is delightful. A very hard unresponsive ground is not pleasing, and it is tiring. Then near courts for summer use there should always be trees to give shade. Winter courts, asphalted, should be enclosed with Cupresses or Holly hedges, and may be more remote from the mansion.—A. D.

— MAGNOLIA CONSPICUA.—In several gardens about London this beautiful species is flowering grandly. At Kew, a large healthy specimen growing in the Azalea garden is now (April 15th) at its best, every twig being loaded with large, sweetly scented, pure white blossoms. Every garden where hardy trees and shrubs are grown to any extent—especially in the southern counties—should possess one or more specimens of this, for, if given a position sheltered from cold winds, and planted well at the commencement in a mixture of peat and loam, it will give little or no trouble afterwards, and will, every spring, be literally smothered with flowers. There are numerous hybrids in cultivation, the result of crosses between this species and others. Of the hybrids several may be seen at Kew, the largest plant being a magnificent specimen of *M. Soulangeana* growing near the plant of *conspicua*. It is a much larger plant than the parent, measuring about 14 feet each way, and is completely covered with purple and white flowers.—K. R.

— GARDENING APPOINTMENTS.—Mr. Thomas Winksill, late head gardener to A. R. Sladen, Esq., Cleeve House, Windermere, has been appointed head gardener to J. Charlton Parr, Esq., Staunton Park, Staunton-on-Arrow, Herefordshire. Mr. G. A. Bishop, late head gardener at Wightwick Manor, Wolverhampton, has been appointed by the Secretary of State for the Colonies, superintendent of the Botanic Station, Bermuda, and expects to enter on his important charge during the ensuing month. Mr. Bishop has been chosen strictly by varied qualifications for the position which all who know him will not doubt his ability to fill creditably and well.

— WISTARIA SINENSIS.—As a quick-growing, free-flowering, hardy climber this has no equal, and judging from the numbers that are found in all parts of the country, it enjoys well-deserved popularity. It is not, however, as a climbing plant for outside that I wish to bring it to notice now, but as a pot plant for the greenhouse in spring. In the conservatory at Kew a small group of plants, which have been slightly forced, are to be seen, and they are there flowering, if anything, more freely than they do outside. When required for forcing, strong young shoots should be layered. When rooted they should be potted in rich fairly heavy loam, and grown on in pots, flowers being produced the second year after potting. After flowering they should not be planted out, but be fed and grown on in pots. Anyone who gives this plant a fair trial for this work cannot fail to be pleased with the results.—KEWITE.

— TOPPING RASPBERRY AND BLACKBERRY PLANTS.—In commercial fruit growing it is almost a universal practice to top the canes of Raspberries and Blackberries when growing in order to make them stocky and self-supporting, as this is a great saving of time and expense. The canes have their tops pinched off when about 2 feet high. The side shoots, which come then, add another foot or two of length before the season is over. This process gives stout bushes, which sustain themselves without any staking or support. When the winter is over the side shoots are clipped back a little, and nothing else is required. These stocky, self-supporting canes, though bearing more berries than those not treated as these were, do not, says a writer in an American journal, bear more weight of fruit. The largest berries come from plants let grow as they will for the season, and cut back to 3 or 4 feet in early spring. Growers must decide between large berries and self-supporting plants. In England there are plenty of Raspberry canes that support themselves without being topped in summer.

— THE EDIBLE PASSION FLOWER.—For draping pillars and arches in the stove, *Passiflora edulis* ranks as one of the most magnificent climbers we have, for when planted in a restricted border it grows luxuriantly, often making shoots of 12 feet or more in one season. The flowers of this species are very beautiful, and are succeeded by handsome purple fruits, which are much appreciated by many persons. The leaves are of a deep glossy green colour, and form a fine contrast to the purple fruits, and for this reason they are admirably adapted for dishes of choice dessert fruits, such as Bananas, Figs, and Peaches. *P. edulis* may be readily propagated by means of cuttings or layers, and during the growing season abundance of root moisture with occasional applications of liquid manure should be given the plants, accompanied with frequent syringings to keep down red spider. I have seen this plant growing well in a cool house, but much better results are obtained by giving it a position in the stove, provided that a portion of the roof near the ventilators can be devoted to it, a stagnant atmosphere being prejudicial to the setting of the flowers.—H. T. M., *Stoncleigh*.

— NATIONAL AMATEUR GARDENERS' ASSOCIATION (LIVERPOOL BRANCH).—On Thursday evening the third meeting of the season was held in the Common Hall, Hackins Hey, Liverpool, the President (J. H. Drake, Esq.) occupying the chair. There was an excellent attendance of members, and the exhibits were much above the average, making altogether a pretty display. Mr. Lunt won with a handsome *Azalea indica*, Mr. Cangle following. The cut Roses staged by Mr. Hoskyn were of superb form and quality, the prize for Fern and miscellaneous cut flowers being taken by Messrs. Lunt and Cangle, these gentlemen also dividing the monthly special prize. The flowers and plants staged for points were exceptionally good. Mr. J. Cliffe, gardener to J. Lawson, Esq., Waterloo, gave an admirable lecture on "Stopping and Trimming Chrysanthemums," which was listened to with the greatest attention, his advice being eminently practical; a vote of thanks was deservedly accorded. Messrs. Smyth, Cooper, and Cangle carried out the duties in connection with the meeting most satisfactorily. Mr. R. Pinnington, Roby, had a fine exhibit of cut flowers, which was much appreciated.

— **SHIRLEY GARDENERS' ASSOCIATION.**—The monthly meeting of the above Society was held at the Parish Room, Shirley, Southampton, on the 18th inst., Mr. B. Ladhams presiding over a fair attendance of members. Mr. Jesse Jones, The Gardens, Terrace House, Polygon, Southampton, gave a very interesting and useful paper on "Table Plants and Plants for House Decoration."

— **TREE FERNS.**—*Alsophila australis* and *A. excelsa* are both rapid-growing Tree Ferns, the last named especially soon attaining to the arborescent state. The habit of growth of these two varieties differs somewhat. The fronds of *A. australis* have a horizontal or spreading growth, while those of *A. excelsa* are more upright, especially at the base, whence they curve in a graceful arching manner.—S.

— **PRUNUS SPINOSA FLORE-PLENO.**—The double flowered form of the Blackthorn ranks high among the dwarf *Prunus*, both from the beauty of its pure white flowers and the freedom with which they are produced. It does not grow nearly so tall as the type, but makes a dense bush with stiff spur-like branches, upon the whole of which large numbers of flowers are borne. It is at present by no means common, but deserves being taken in hand and increased largely, for besides being useful for the shrubbery it could be used with advantage where cover is needed for game. It can be increased by grafting on stocks of the type.—W. D.

— **MAGNOLIA STELLATA.**—Now that good plants of this species can be imported cheaply and in good condition from Japan, it is fast becoming one of the most popular flowering shrubs, both for outside work and forcing. At Kew several beds are to be seen, which during the Easter holidays were—and for several weeks to come will be—perfect pictures, the bushes being completely smothered with sweetly scented, glistening white, star-shaped blossoms. An idea of its free-flowering qualities may be gathered from the fact that some of the plants, 3 feet high by 3 feet wide, are carrying 150 open flowers and buds. When planting it is advisable to prepare beds of half peat and half loam, for although it will grow in loam alone, it thrives much better in the mixture. For forcing the plants should be grown in an open border during summer, and lifted in October, potted, and plunged outside until required. Strong heat should be avoided when forcing, the flowers opening and lasting better when gentle heat only is used.—D., *Kew*.

— **READING GARDENERS' SOCIETY.**—One of the most interesting and successful meetings of the Association was that held on Monday last, when the prizes offered by Mr. Leonard Sutton at the commencement of the season, 1898, for the best essays on "How to Keep the Greenhouse Gay from October 1st to March 31st," and "How to Crop the Vegetable Garden to Insure the Best Varieties of Vegetables from October 1st to March 31st," were awarded to the successful competitors. The interest taken in the competition was greater than anticipated, thirteen members sending in papers, and a good gathering of members assembled to learn the result and to hear the prizewinning papers read by the writers. After the formal business had been transacted Mr. C. B. Stevens announced the awards as follows:—"How to Keep a Greenhouse Gay": First, Mr. A. W. Blake, foreman, The Gardens, East Thorpe, Reading; second, Mr. G. Stanton, The Gardens, Park Place, Henley-on-Thames; and third, Mr. John Botley, foreman, The Gardens, Warfield Hall, Bracknell (a contributor to the "Young Gardeners' Domain"). "How to Crop the Vegetable Garden": First, Mr. E. Trollope, The Gardens, Coombe Lodge, Whitechurch; second, Mr. H. Wilson, The Gardens, Lower Redlands, Reading; and third, Mr. G. Hinton, The Gardens, Sherwood Lodge, Reading. Mr. L. Sutton, in presenting the prizes, said that he considered the subject of essay writing was one of the most useful and beneficial to the members that the Society could take up, for it encouraged the putting of one's ideas on paper, and at the present time it was those gardeners who could go to their employers with well thought out ideas who would prove successful; it would also be of the utmost value to the young gardeners who entered these competitions, for they would reap the benefit of their study and research in after life. The President then called upon the various winners to read their papers, and they created great interest. A vote of thanks was passed to Mr. L. Sutton for his kindness in giving the prizes. Owing to the success of the venture the Association has decided to take up this interesting subject as a part of its programme for season 1898-99, and a vote was passed that a sum not exceeding £8 should be devoted for the purpose, but that the competition should be divided into various grades, thus giving all members an equal chance to compete. Cut flowers were staged by Mr. Woolford, The Gardens, East Thorpe; *Prunus sinensis flore-pleno* by Mr. Swansborough, Warfield Hall Gardens; and vegetables by Mr. Stone and Mr. Hinton.

— **FRENCH AND AFRICAN MARIGOLDS.**—It is better to have dwarf and stocky young plants of these by sowing now thinly in boxes, than to use tall overgrown plants, which invariably result when the seed is sown too early. Plants from early raising need transplanting, but when sown thinly and at a comparatively late period this is not necessary.—S.

— **PROPAGATING ECHEVERIA METALLICA.**—When plants of *Echeveria metallica* become tall, and a greater part of the stem bare of leaves, it is a good plan to cut off the tops just below the healthy leaves, and make of them dwarf plants. Two inches of stem may be left, and if the heads are placed in empty pots, with the lower leaves resting on the rims, the stems will emit roots. Let the pots stand on the stage among others in an ordinary greenhouse until abundance of fine roots have developed, then the heads may be potted in sandy soil in the ordinary way.—E. D. S.

— **METROPOLITAN PUBLIC GARDENS ASSOCIATION.**—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, W., Sir William Vincent, Bart., Vice-Chairman, presiding, it was announced that the Inner Temple Buildings Bill, in which powers were sought to build on the frontage adjoining the Thames Embankment, had been rejected by the Select Committee of the House of Lords. It was agreed, if its maintenance were secured, and if funds were forthcoming, to lay out the churchyard of St. Mary, Plaistow, E., at a cost of £300. It was also reported that progress had been made in the laying out of several grounds, and it was stated that Charles Square, Hoxton, had been commenced, and that trees had been planted in the new riverside ground at Putney. Ham Common, and Lammas Lands, Bridgewater Square, the "Postmen's Park," Pymme's Park, Edmonton, and some vacant land at New Cross, also received attention.

— **CARE OF TREES.**—It is gratifying to note, says a transatlantic contemporary, the rapidly growing sentiment in regard to the care of trees. The following from the Taunton, Mass., "Gazette" has the true ring:—"The practice in vogue during the past ten years of ruthlessly hacking down any tree, no matter of how magnificent proportions, in order to make room for an unarchitectural building of some kind is being frowned upon owing to the increased appreciativeness of shade and scenery. It takes a tree a long while to grow. After it is full-grown it is a valuable piece of property. It cools the earth in its vicinity, it aids in keeping the atmosphere pure, it attracts the birds and throws a faint suspicion of country joys about the bit of noisy city in which it is located. Leave a street which is bare of trees and come to one which has one or two stately Elms upon it and note how sensible is the change. It speaks well for the general advance in culture among the people that this movement is being made, and it should increase not only so far as it relates to preserving the trees already planted, but in urging the planting of more that they may grow and add their benefits to the next generation. It is well to remind our young people that shade trees should have greater respect paid to them."

— **PREVENTING THE GOOSEBERRY MILDEW.**—Mr. C. P. Close says:—"For ten years the New York Agricultural Experiment Station has advocated potassium sulphide as the best remedy for Gooseberry mildew. In the season of 1897, potassium sulphide, Bordeaux mixture, lysol, and formalin were tested side by side. The plantation was divided into six sections. In two of these the spraying was begun very early, just as buds were breaking; in two others eleven days later; and in the remaining two sections twelve days after the preceding two sections. The first mildew appeared May 26th. By June 7th portions of the plantation were badly mildewed. At this date the lysol and formalin seemed to have done no good. Bordeaux mixture was more effective, but not so good as potassium sulphide where the treatments were begun very early and medium early. All of the fruit was picked July 6th and 7th, so as to market it green. Bushes sprayed very early with potassium sulphide at the rate of 1 oz. to 3 gallons of water gave only 5 per cent. of mildewed fruit; those sprayed very early with it at the rate of 1 oz. to 2 gallons of water gave 6.6 per cent. Bushes sprayed very early with lysol, 1 oz. to 1 gallon of water, gave 24.5 per cent., and those sprayed very early with Bordeaux mixture gave 37.4 per cent. of mildewed fruit, while the untreated bushes gave 57.7 per cent. to 78.7 per cent. The foliage was not injured by any of the fungicides. At 18 cents per pound for potassium sulphide, the cost of the solution which gave the best results is about one-fifth of one cent per bush for the seven sprayings. The station recommends potassium sulphide, 1 oz. to 3 gallons, or 1 oz. to 2 gallons of water, as the most effective fungicide for Gooseberry mildew. As a rule, only the English varieties and their seedlings are attacked by mildew although the American varieties are not always exempt."

— **WAR AND THE FRUIT TRADE.**—A large fruit importer says : "A war between America and Spain will paralyse the fruit trade of this country. That is the unanimous opinion of merchants. There are about eight lines of steamers engaged in the fruit trade, and most of the imports are direct from Spain to Liverpool. Even the London market is supplied mostly through Liverpool."

— **SELAGINELLA KRAUSSIANA.**—When grown in pots and pans the whole of the stock ought to be divided and repotted in clean receptacles and fresh soil at this season. Any clean young bit will grow, but the readiest method is to divide a vigorous clump into small pieces, planting one piece in the centre of each pot, or if in pans several will be necessary to cover the surface. They quickly take root and spread. Stand the pots in a shady position in a vinery, greenhouse, or stove, sprinkling lightly with a syringe daily until established.—E.

— **GROWING PLANTS IN SCHOOL ROOMS.**—The Assistant Medical Inspector of the Philadelphia Board of Health says :—"Growing plants should not be used as permanent school-room decorations ; many have medicinal odours to which some children are quite susceptible, and they may serve to harbour disease germs in the dust that may accumulate about them." Only for the statement that there are "many" such kinds, one might suppose people grow poison Vines for window plants. As plants absorb the carbonic acid from the children's lungs, they are Nature's great purifier of bad air. It would have been as well if the learned gentleman had given a list of those that possess "medicinal" odours susceptible (of disease) to some children ; and why the dust on a live leaf should harbour disease germs more than the walls or permanent furniture, the tops of which are seldom dusted, might be clearer. Unfortunately, local Boards of Health are usually held as sacred as the oracles of the pagans ; and the beautiful window flowers, for which so many of the public schools are famous, will probably have to go. The pretty little conservatories attached to many city homes may next be banished, and the dust-collecting, disease-germ-harboursing shrubbery in the city yards share the same fate !—("Meehans' Monthly.")

ROUND OAK GARDENS.

LOOKING through the gardens of N. L. Cohen, Esq., Round Oak, Egham, I noticed in one of the houses a good sized tree, some ten or twelve years old, of Alexander Peach, carrying an abundant crop of fruit. Mr. Sturt, the gardener, told me that he never had trouble with the variety in bud-dropping, which is so commonly complained of. I noticed that the growth on the tree bore in no sense a luxuriant aspect, and learned that such appearance was due to occasional root-pruning, as check in that way administered in repressing robust growth had the effect of checking bud-dropping. It would be interesting to learn whether others have adopted this repressive course with the variety with similar results, or otherwise. In many cases, as common observation shows, there is too much of haste to furnish a Peach house, and thus too robust growth is engendered.

Beside one of the paths in the kitchen garden there run on each side broad borders full of very strong plants of good Hybrid Perpetual Roses. I have never seen Rose bushes cut back so completely as these were, when I saw them a few days since. The stools are 2½ feet apart, and many of them close to the soil, to which they were close cut back, were 9 and 10 inches across. They are treated in this way every year, with the result that as the spring advances up come grand shoots, chiefly from the bases of the previous season's wood, to heights of from 3 to 4 feet, and carrying superb blooms. Presently the plants receive a good mulching of manure, and if needed liberal waterings. It is interesting thus to note this very drastic style of pruning Roses, whilst some people hardly prune at all, or they do so very tenderly. Roses evidently naturally like to recuperate as they do at Egham.

When Mr. Sturt went to Egham, some fifteen years ago, he found a couple of old and almost exhausted Asparagus beds. Most gardeners would probably have condemned them to early destruction, or at least so soon as new beds could be induced to take their places. Not so this gardener. He started to renovate by removing entirely much of the top soil, replacing it with fresh, and here and there filling vacancies with new roots. Then a good dressing of manure also was added, and summer feeding liberally given. The result has for a long time been seen in entire resuscitation. The soil on the beds is higher, for before it had become quite thin ; the summer growth is double the density and height of what it used to be, and both beds give splendid crops of stems. This illustration of remedial measures in relation to Asparagus culture is worth notice.

I have one other note from Round Oak. "I see you have some ridge Mushroom beds," I remarked. "Come and look at them," said Mr. Sturt. He then from one lifted the light canvas cloth thrown over it, drew away the covering of litter, and revealed such clusters of fine clean brown Mushrooms as are not commonly seen ; yet he had been cutting from this bed since January, when there was a good crop, then the bed

had a rest, and started bearing again. "My people," said he, "prefer Mushrooms from outdoor beds to those grown inside, as having firmer flesh and richer flavour. I have had beds frozen-in several inches, yet when mild weather has come they have started bearing again." Mr. Sturt's sample was just of that fine solid character as were the Mushrooms Mr. J. Miller sent up from Ruxley Lodge to the Drill Hall on the 12th inst.—A. D.

TEN MINUTES' NOTES.

I AGAIN subscribe a trio of notes appertaining to fruit and fruit prospects, together with a reference to the current mode of stopping Vine growths, with a set off against this hard and fast rule, and invite other opinions on the subject. I also append a note on flavour prizes for fruit.

PLETHORA OF FRUIT BLOSSOMS.

Many persons who are not experienced cultivators will be rejoicing in the splendid lot of blossom on their trees, and congratulating each other on the bountiful crops of fruit of which they feel certain. I, for one, would rather see a fifth part of the bloom instead of such a dense crowd. Certainly blossom-laden trees have a charming appearance, but the superabundance now opening on Pears, Plums, and Cherries will be so weakened from want of nourishment, that a great percentage must fall and leave no fruit behind. What, then, is to be done to secure if possible a fair crop of fruit ? It is, of course, out of all reason to thin out the fruit spurs, and it is equally impossible to reduce the blossoms on any large scale, so as to throw more productive power into those left. There is but one way that appears to me to be practicable in this very dry season that might tend to lessen the chances of disappointment, and that is to well water all the trees where it is possible, especially wall trees. The soil must be unusually dry for the time of year, and if there are conveniences whereby all the trees may be copiously watered with a minimum of labour expended, it will be work well done. A good mulching of half-decayed manure around each tree afterwards will tend to check evaporation. I feel sure that such an excess of blossom associated with the present dry state of the soil will account for many blanks later on, if some such measure as suggested is not acted upon to assist Nature in her over-bountiful supply in one direction, and a deficiency of moisture on the other.

STOPPING VINES.

Gardeners generally have been so tutored into the orthodox system during their early career of stopping Vine shoots two joints beyond the bunch, that it is hard to discontinue the practice, and launch out from what I am led to think seems wrong teaching, and contrary to the laws of Nature. It seems to me that the practice of stopping all shoots in the same way needs a little rectification. I know several good Grape growers who allow much more than the orthodox extension, especially with Madresfield Court, to counteract any sudden rush of sap, that would otherwise burst the berries. In a house of Hamburgs one expects shoots in various degrees of vigour. Frequently a strong shoot will be bunchless, while a weaker, perhaps on the same spur, will show two bunches. Both laterals are needed to furnish their allotted space. What about stopping such as these ? I should certainly check the former at the third or fourth leaf, and allow the fruiting branch more freedom by running it on for a week or two longer, then stopping at the third or fourth leaf from the bunch. The same principle adopted throughout the house of stopping the strong shoots closely, and allowing the weaker ones to have the run of sap, must tend to equalisation. It is not always the strongest shoots, far from it, that produce the best results. I have a Golden Champion Vine that broke very strongly, but I can only count five or six bunches on it. Near by is a one-year-old cane of Muscat of Alexandria, showing bunches all its length. I believe Mrs. Pince is the better for a liberal shoot extension. I am of opinion that a little deviation in practice, exercised with proper judgment, is desirable in the mode of stopping Vines.

FLAVOUR PRIZES (R.H.S.).

I do not know, but I should imagine that a great percentage of gardeners are not aware of the rules and regulations enabling one to enter into competition for the excellent prizes given by Messrs. Veitch and Sons for the best dishes of Pears and Apples, the test to be flavour, the "testers" the Fruit Committee of the R.H.S. The same exhibitors' names have appeared time after time (all credit to them), that a stranger does not seem to have had a look in. Why do not more gardeners enter the arena and make the contest keener, and more what it was intended to be—an "object" lesson, or a thorough test of the merits or demerits of our English grown fruit ? It would stimulate our backward friends who have excellent fruit walls and quarters to action, if the Editor would again publish the rules and conditions, and at the same time express an opinion of the value of these contests. Any hints would be highly appreciated that would tend to make the competitions keener. I feel sure the promoters of these money prizes would be gratified to find a few more zealous cultivators taking part in what appears to be a disappointingly weak (in numbers) competition.—GEO. DYKE, *Stubton Gardens, Newark.*

[It is too late now to republish the conditions referred to. The season is practically over. If prizes of the same nature are offered in the autumn we shall readily make the particulars known. Possibly if our able correspondent had been one of the "testers" at several of the meetings he would not have found the competition so "weak" as he infers. It was often quite strong enough for the palates of the adjudicators, which seemed ready for a rest after the work was done.]

ALLAMANDAS AND THEIR CULTURE.

(Concluded from page 320.)

WATERING.

IN the winter months Allamandas require little water—indeed, the less the better provided the wood is kept sound and plump and the leaves present do not flag. Understand that the soil must accord—that is, appear and be apparently dry, for a plant may not want water because the soil has become sodden through defective drainage. That must never happen, for thorough drainage is essential. In the early stages of growth water must be given sparingly; suffice that the soil be evenly moist, inclining to the dry rather than wet side, for roots are wanted, and also a sturdy, thoroughly solidified growth. As the plants make growth increase the water, never giving any until the soil is getting dry; then a full supply to moisten the ball right through, and always afford it before the foliage is distressed for lack of due moisture.

Feeding may begin as soon as the flower buds form, or even before. I have found nothing better than stable and cow house drainings, or the liquid from a manure heap. The latter is the better of the two, and the former improved by a peck of fowl manure to each 30 gallons; or better still, half a peck each of fowl excreta and soot, adding a pound of superphosphate (37 per cent. soluble phosphate of lime). This beats all the liquid manures of which I have cognisance, diluted with five times the bulk of water. It must be of the same temperature as that of the structure in which the plants are growing. Once or twice a week is often enough to supply it, unless the plants are in small pots for the size of their spread of heads. These highly fed plants, however, as before stated, sometimes collapse suddenly.

For top-dressing nothing supersedes dried blood mixed with 5 per cent. of freshly slaked best chalk lime, and as much dried wood ashes as can be worked in (a very difficult process, but easier with the lime, and easier still if the warm blood be stirred until cold) to the consistency of stiff crumbling mortar. This covered with gypsum or best air-slaked chalk lime, and left till dry, suits almost anything, a handful being used per square yard. Vines like it immensely, so do Allamandas grown in borders, also those in pots for a change with the liquid manure. The ceasing from growth and flowering will indicate the time to lessen the supplies of water, reducing gradually, not suddenly, as the maturity of the wood must be complete to provide for the following year's flowering.

PRUNING.

The plants must be pruned annually in January or February. Extending plants on the long-rod system—that is, leaving the strong well matured shoots several joints in length, mainly to get the coming shoots well placed for covering a roof trellis, otherwise this long pruning cannot be advised. The best results follow close pruning, cutting the previous year's shoots back to a joint or two of the old wood. This answers admirably, and points to the wood never being too hard or well ripened for the production of floriferous growths.

TEMPERATURE.

Though this fine genus of plants may be said to rest (and they do, in spite of the hair-splitters) from late summer to over New Year's Day, concentrating, it may be, their forces for future developments, they should never be subjected to a lower temperature than 55°. This occurs very seldom in the stove, the night heat and on dull days during the winter being kept at 60° to 65°, so that the plants get exactly what they require—a resting and concentrating of power season. In summer, or from mid-February onward, stove heat by day runs 70° to 75°, in spite of wind or anything else in the shape of weather, and when the sun shines the heat rises to 80°, 85°, 90°, or more, this just suiting the plants, only give air, so that the glass is not clouded with moisture to obstruct the light and absorb the heat. Then the sun's rays strike right into the Allamanda foliage, the chlorophyll granules increase, the leaves become the deepest green, followed under good management by the richest of yellow flowers.

ATMOSPHERIC MOISTURE.

The Allamandas are remarkably clean plants, neither fungoid (unless sudden collapse have that agency) nor insect pests troubling them, and they do not in consequence require the washing some stove kinds must have to keep them clean and healthy. The usual sprinkling of the paths and other surfaces two or three times a day meets all their requirements in respect of air moisture. Though an occasional light syringing may be indulged in, an everyday washing does Allamandas more harm than good, and is much better left undone. Indeed, *A. grandiflora* marks its dislike of water hanging on the leaves by these turning brown at the tips and edges, which are a great disfigurement, often spoiling the appearance of an otherwise good specimen. Other species also become more or less browned by the

needless drenching procedure; therefore avoid it, for good foliage, as well as flowers, are important considerations in either potted or planted-out specimens.

SELECTION OF VARIETIES.

A. Aubleti.—Flowers yellow; large. June. Leaves four to five in a whorl, broad-oblong, acuminate, rather hairy beneath. Guiana, 1848. A rather uncommon species, but fine for trellis training.

A. cathartica.—Flowers yellow. June. Leaves four in a whorl, glabrous. Guiana, 1785. Excellent for planting in a border and training up the roof of a house, but flowers neither so freely produced nor so large as some other species or varieties, yet distinct and desirable, being relatively hardier than most others.

A. Chelsoni.—Flowers yellow; large. Summer. A garden hybrid, very free, producing its yellow blooms all through the summer. Stiff and hard in the wood, this splendid plant does not readily admit of trellis training; but for the roof of a house has few equals, the flowers having (for an Allamanda) considerable persistence, hence one of the best kinds for cutting.

A. grandiflora.—Flowers pale yellow, distinct. June, Brazil, 1844. A slender-growing plant; very free bloomer, and excellent for formal trellis training. It does not succeed well on its own roots, and hence is commonly worked on a freer and hardier stock.

A. Hendersoni.—Flowers deep yellow; large. Summer. Garden hybrid. A very free grower and bloomer; excellent for the roof of a house either planted in a border or grown in pots. One of the best for cutting, but the plants (with me) liable to collapse suddenly, especially after great floriferousness and high feeding when grown in pots, this taking place about August. Can any correspondent account for such collapse?

A. neriifolia.—Flowers deep golden yellow, streaked with orange, rather small for an Allamanda, between funnel and bell-shaped; tube wide, panicle many-flowered. June—indeed, almost the year round when growths are regulated by cutting some back. Leaves oblong, on short petioles. South America, 1847. Shrub erect, glabrous; 3 to 4 feet. The hardiest species, succeeding in a cool stove.

A. nobilis.—Flowers bright pale yellow, deeper tinted in the throat, fine circular form; large. July. Leaves in whorls of three or four, sessile, oblong, hairy, especially beneath and on the midrib. A strong-growing species, and certainly one of the best of the genus, giving a long succession of bloom. Brazil, 1867.

A. Schottii.—Flowers yellow, throat beautifully striped with rich brown; large. August and September. Leaves four in a whorl, oblong, glabrous. Brazil, 1847. A very free blooming species, strong grower, yet suitable for trellis training, but for floral production best grown on the roof system.

A. verticillata.—Flowers yellow; large. June. Leaves six in a whorl, glabrous. South America, 1812.

A. Wardleana.—Flowers yellow; large. Summer. A desirable climbing variety, suitable for trellis or roof training. For all practical purposes the same as Wardleyana.

A. Williamsi.—Flowers very bright yellow, and of medium size. Habit compact and bushy. A good variety for culture in pots. Probably a garden hybrid. (See illustration, fig. 67.)—G. ABBEY.

TYING DOWN VINE SHOOTS.

VINE shoots in midseason houses are now growing apace, and those in late ones are advancing rapidly, and in either case unless the work of tying down the young shoots is carefully performed, the loss of many a promising bunch is inevitable. Fortunately there is a tendency now to fix the trellises farther from the glass than formerly, and those who have departed from the "beaten track" in this respect soon perceive how great are the advantages of such a practice. In summertime it is much easier to keep the Vines free from red spider, and during the early stages of growth the shoots need not be interfered with until the dangerous stage is passed. After the fruit is set the shoots possess a certain amount of toughness, and are less likely to break off at the heel.

Taking these things into consideration, common sense suggests that in all instances where there is a space of 18 inches between the trellis and the glass, the shoots should be stopped, but no attempt made to tie them down till after the fruit is set. There are many cultivators, however, who have to deal with Vine rods trained only a foot from the glass. Where the houses have sufficient height matters may be improved by lowering the rods a few inches below the trellis, but in many cases this way out of the difficulty cannot be pursued because the houses are too low. The difficulty can then only be met by stopping at one or two joints beyond the bunch, and using every possible care in tying down, as well as by delaying the latter operation as long as possible. I have lately had to deal with a house of this description, and as on many former occasions I have met with

difficulties, I thought, therefore, that a few remarks on the subject might be of service to readers of the *Journal of Horticulture*.

An important point to remember is that the tying down is best performed in the early morning and evening, as the shoots are then stiff and upright, whereas during a bright day they are limp. If tied down in that state there is great danger of losing many shoots,

noted closely will show practical cultivators what great advantages they may gain by performing the operation of tying down Vine shoots at the most suitable period of the day, or rather during the most suitable weather.

Even when these precautions are taken it is not safe to tie down the shoots of some varieties very early. Black Hamburgs when

FIG. 67.—ALLAMANDA WILLIAMSII.

because when the leaves freshen and stiffen during the evening the tying material is drawn tightly, with the inevitable result that many shoots break away at the heel.

Now let us examine the opposite state of affairs—viz., the results of tying down while the weather is dull. The shoots are then fresh and rigid, and no tightening of the tying material takes place; but, on the contrary, it gets looser as the leaves become limp under the influence of bright sunshine. These apparently trivial matters if

forced early are very brittle in growth. Gros Maroc and Black Alicante may also be included among varieties which require great care. A plan I often adopt in dealing with them is, when the shoots touch the glass, to merely tie the point down slightly, without attempting to put any pressure upon the lower part of the shoot; by doing this the terminal leaf may be kept safe from being scorched until the shoots become sufficiently hardened to be tied down in the usual way.

The loss of a spur so spoils the appearance of a Vine, that every precaution should be taken to avoid its occurrence. At disbudding time I make a practice of leaving an extra shoot upon any spur which seems likely to give trouble; and in other instances, where the spurs are old and long, if two shoots are formed upon them, I stop one back to the lower bud, then if the principal shoot happens to get broken the stopped one will send out a strong lateral, and thus avoid an ugly gap on the Vine rod.—VITIS.

PROFITABLE FRUIT GROWING.

THERE is excellent sense in the paper appearing on page 322 of your last week's issue, and I quite anticipate its continuation. However, some curious misconceptions crop up on such occasions, an instance in point of which is the remark, "We have to face competition from every quarter of the globe." This is not correct in a literal sense, for we have only to face real competition in numerous and important products of these isles from countries north of the Equator. The products of the southern half are to the largest extent a welcome supplement to our own supplies when off.

I well remember my surprise when, a couple of years ago, on the occasion of a meeting in connection with the R.H.S. fruit show, a discussion was reported. An Australian cousin was present, and stated a few points of view concerning Apples, when he was somewhat unceremoniously rebuked by a home grower, who told him in so many words we would be rather without Australian competition. Shortsightedness alone was responsible for the unfriendly greeting of the Australian visitor, for it is manifest that when in April and May the Antipodean supplies of Apples reach us there is scarcely an Apple of English growth to be had. On the other hand, the Australians will have to improve the flavour of their Apples if they wish to be successful, for only that element will dispose of the larger quantities when in due time they will be produced.

A dream of the future may be indulged in. When the cousins at the Antipodes have prospered, and formed more populous communities, there may be a huge trade arising by exchange of seasonable fruit between the northern and southern branches of our future federated empire.—H. H. R., *Forest Hill*.

NOTES ON ASPARAGUS.

IF well attended to in spring this favourite and valuable vegetable will require little attention throughout the season. It is a great advantage for cultivators to raise their own young stock, as Asparagus roots suffer much through being taken up, sent a long distance, and kept out of the soil for a considerable time. Many roots will die from this treatment, and more still will receive a check from which they will not readily recover. When everyone raises his own plants this difficulty has not to be contended with, as the ground may be ready for the plants before they are taken up, and then they need not be out of the soil or exposed to the air for more than a few minutes. In this way they will experience no check from being transplanted, and the advantage of one or two years' growth will be gained. Two or three hundred plants may be raised in a bed 4 feet wide and 10 or 12 yards long. April is the most suitable month to sow the seed, and it may be dealt with like Onions or any other ordinary crop.

Transplanting the young roots into their permanent quarters is an operation of the greatest importance, as on this depends their ultimate success. Soil for Asparagus should always be thoroughly drained. When wet and retentive many roots perish every winter, and the plants are never satisfactory. Light manures, such as horse droppings and gritty road scrapings, suit Asparagus best. The heavier the soil the more of this should be applied, and river or sea sand added in proportions according to the natural condition of the soil will be found to answer admirably. Wood ashes are good, but coal ashes are worse than useless. They may be placed in the bottom as drainage, but amongst the roots they are injurious.

Asparagus roots do not run deeply, but live and feed near the surface, and this should be remembered in making the soil ready. Trenching and deep digging are beneficial in helping to improve and drain the surface, but to manure a piece 2 feet deep or more is a mistake. Enrich the surface by all means and make it as good as possible. Fork or dig large quantities of nourishing manure into it immediately before planting, and the results will invariably be satisfactory.

The time of planting must be determined by the condition of the roots. It is not any advantage to plant long before growth begins, and it is injurious to lift and plant after growth has fully started. The best time is when the stems are commencing growth. In some parts of the country this may be about the end of February, and in others not until April. Recently in looking over some young roots I found them just starting into growth, and they were transplanted on the same day.

Asparagus beds are now almost out of date, except in very wet or water-logged situations. The most profitable way is to plant row after row on a piece of ground and never trouble about beds. The roots should be planted from 2 to 3 feet apart each way, and only 3 or 4 inches below the surface. Roots from one to two years old will be about 1 foot in diameter. The holes must not be less than this, and when placed in them none of the roots should curl up. Lay them flat and put two or three handfuls of sand over each, then finish off with the soil which was taken out. Make this quite firm over the roots, and planting is finished.

Older roots which have been planted some years are always benefited by top-dressing in winter and spring. A good handful of salt, guano, or a mixture of both may be shaken over each crown at present with advantage to what is coming in the way of heads. Forking amongst the roots should never be allowed. If the crowns have been mulched throughout the winter this covering may be taken off, placed between the rows and forked in, but to try and work this amongst the roots would end in breaking many of them, and probably injure several of the crowns. Old plantations which have long since seen their best days should not be preserved. They are the reverse of profitable. Cut them to the last this year and then destroy them.

Owners of young plantations are often puzzled as to when to begin to cut Asparagus. Must it be two, three, or four years old? My plan is to cut as soon as the "grass" produced is strong enough to use. Two-year-old plants will sometimes throw up heads which are cut without fear, but poor roots badly managed would show nothing worth having for a long time. Leaving the weak and cutting the strong is a good method. Were they all left the strong would remain so throughout, and the small ones would never come to anything. By cutting and using the finest the small growths are forced to develop, and so a crop is obtained, and the plantation is constantly improving.—J.

GLEANINGS FROM GHENT.

HOW THE BELGIANS BEAT US, AND HOW WE BEAT THEM.

QUINQUENNIALS are not a popular form of function in a country in a hurry. Great Britain is a country in a hurry—*ergo*, her exhibitions come at short intervals, and, big or little, they are very soon forgotten. That perhaps is why, in the rare moments of self-depreciation which the assertive Saxon permits himself, he says that they do things better in France. Perhaps they do; but it should be recognised at the very beginning that they likewise take a good deal more time about it, and perhaps if we packed five Temple Shows into one field, we should make as big an effect with it in our rough and ready way, as some of our Continental friends do with their admittedly fine displays. Having thus put matters on a proper basis, I can proceed to give a few jottings (which will perhaps not follow any stilted type) about the latest Ghent quinquennial. I shall make no more qualifications than the one which I have just quoted, but I shall make as many comparisons as struck me, whether they tickle or thwack us, for of such is the Law of Justice.

I did not meet the Man from Bedfordshire at Ghent, but I met him, as is appropriate, on the boat. Perhaps, not sharing my own particular partiality for Robt. Louis Stevenson, you do not know who the Man from Bedfordshire is. He is the man who is going on the sea for the first time, but who, on the strength of the fact that Britannia rules the waves, expresses unmitigated contempt for every other nationality as soon as he gets afloat. He then proceeds to criticise the boat (no small presumption in the case of the Great Eastern Company, which has most comfortable and admirably fitted vessels) and the captain's knowledge of maritime matters, after which he abruptly retires to be seasick. This culminating stage rid me of the man from Bedfordshire, but men of a few other counties came later on into view. There was, for instance, a man from Kent, in the substantial person of Mr. Laing; a man from Buckinghamshire, in the jovial form of Mr. H. Turner; several men from Middlesex, the nursery-element in the metropolitan county being represented by Mr. Jas. Veitch, Mr. H. Williams, and Mr. Cutbush; and the literary by Dr. Masters, Mr. Hudson, and Mr. O'Brien. From Lancashire came Mr. Ker, from Surrey Mr. G. Gordon, and Kent had other representatives in Mr. Cannell, jun., and Mr. H. J. Jones. Professor Bayley Balfour, and Mr. F. W. Moore were the Scottish and Irish delegates.

To begin with a little wholesome flagellation, it may be said that as a whole we have to cry *Peccavi* on at least three grounds. No. 1 is display; No. 2, Ferns and Palms; No. 3, Azaleas. We used to have some Azaleas in the old days a little like the giants of Mr. G. De Walle, but they are not seen now. As to arrangement, we are miles behind the Continentals. We try to put our classes together; they try all they can to put them apart. They consider the people who pay—to wit, the visitors; we consider those who don't—*i.e.*, the exhibitors and the reporters. The Continental system is bad for jury and journalists, but good for everybody else. Which is generally preferable depends on whether you are a payer or a worker. Being both myself, I was never exactly right and never exactly wrong. One thing, however, must be said—neither we in our inferior way, nor the Belgians in their superior one, touched the high-water mark of Hamburg's opening show last year. But that was phenomenal. Discounting all comparisons, however, the taste displayed in the disposal of the plants at Ghent was of an order familiar only to those who have previously seen how much better they do this sort of thing than it is done in England.

One thing which, if surprising, was nevertheless unmistakeable, was the eager interest displayed in the Orchids. The Belgians appear to have found out suddenly that Orchids not only exist, but are worth looking at. Old stagers remarked that the Orchids were not so good as at the last quinquennial, but that they were run after fifty times as much. People talked Orchids in the train and in the street, and directly they got

into the Casino they began to run. In view of their excitement imagination fails to grasp the effect which a really great display, such as the Temple, for instance, would have had upon them. It would be too much to say that the Orchids were poor, but as regards both interest and beauty several Ghents would not have made one Temple. The fact is Belgium is beginning where we left off. This is not insular pride, though it may sound like it. It is the truth.

A splendidly bloomed piece of *Odontoglossum Halli*, exhibited by Mr. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, received attention and a medal. He had a very attractive little group, including *O. crispum Thompsoniae*, *O. Coradinei expansum*, *O. Humeanum splendens*, *O. crispum roseum leucoglossum*, and *O. Wilckeanum nobilior*. In the competitive classes Mr. A. Van Imschoot was the most successful, his collection including as it did *Cypripedium Chamberlainianum*, *Odontoglossum cariniferum*, *Dendrobium Kingianum*, *Odontoglossum Andersoni*, *O. odoratum*, and *Cypripedium Rothschildianum*, all in good condition. Mr. A. A. Peeters, St. Gilles, Brussels, had a bright display, including *Miltonia Bleuana nobilior* and *aurea*, *Zygopetalum Perrenoudi*, *Cattleya Mossiae Reineckiana*, *C. Lawrenceana*, *Odontoglossum crispum punctatum*, *Laelio-Cattleya Hippolyta*, *Cattleya Parthenia gratissima*, *C. intermedia Parthenia*, *Eulophiella Elisabethæ*, and *Mesospinidium vulcanicum*. There were several items of interest in the gold medal collection of Mr. G. Vincke-Dujardin, including *Lycaste Skinneri Augusta*, rich rose; *Odontoglossum crispum excellens*, lemon and brown; *Masdevallia ignea*; *Cypripedium Druryi*, yellow; *Odontoglossum Gabrieli*, lemon, light, with brown bars; *Cypripedium villosum aureum*, *Oncidium macranthum*, *Ansellia africana*, *Epiphronitis Veitchi*, and *Phaius Cooksoni*.

New plants in general drew the special attention of the trade, but in one or two cases that of the public as well. L'Horticulture Internationale (Linden) had a diversified collection, in which were conspicuous *Maranta Funcki*, *Peperomia metallica*, *Caraguata cardinalis*, *Tradescantia delecta* with leaves three or four times the size of *T. zebrina*, and clearly barred, from Peru; *Leea amabilis* var. *splendens*, *Spathiphyllum floribundum*, the Brazilian *Maranta setosa*, *Dichorisandra angustifolia*, *Fittonia gigantea*, *Gunnera manicata*, *Acalypha quadricolor*, *Adiantum lineatum* from Brazil, *Maranta illustris*, *Malpighia ilicifolia*. The last was the plant introduced from Cuba by Mr. J. Linden in 1838. Either from the interesting fact of its being the plant's jubilee, or because of current excitement about the Caribbean island, it attracted a great deal of notice.

In a wing of the large gallery something like a sensation was caused by the group of new plants from Messrs. Sander of St. Albans, prominent amongst which was *Acalypha Sanderi* from New Guinea. Its long "tails" of rosy inflorescence were viewed with astonishment and admiration. Louis called Adolphe, and Adolphe excitedly fetched Zélie. Then they nearly talked its tails off. *Acalypha Godseffiana* also received attention, but next to *Acalypha Sanderi*, the huge plant of *Dracæna Sanderiana*, 7 feet high, and the same through, drew the most notice. *Dracæna Godseffiana*, *Anæctochilus Leopoldi*, and *Odontoglossum crispum Roi Leopold*, were all much remarked.

In a general survey of the show a busy reporter must make pickings here and there. To put everything in proper form would be to evolve order in the work of an hour or two out of the chaos of days. It is easiest to dip here and there. England came gallantly to the front with one great flower. The *Amaryllis* from Messrs. Veitch were worthy of their country. One gentleman told another, who was not close enough to see, the size of the variety *Francisca*. The other threw up his hands in horror at such uncalled for mendacity. Then there was a squeezing, a jostling, a dragging forth of measures, and a staggered, *C'est vrai!* The mendacious one had triumphed to the sixteenth of an inch. The bloom was over 11 inches in diameter. Then a priest measured the flower with his umbrella, and wheezed away into a fit of amazed and unctuous laughter. This variety and several others have not bloomed in England. Perfect in shape and grand in colour was *King of the Belgians*. Big, bold and bright were *Euphrasia* and *Owick*. The whole group was a magnificent one, being distinguished not only for wonderful quality, but great variety of colour. The *Veitchian Sarracenias* and *Nepenthes* were nearly as much admired as the *Amaryllis*, and that may be taken as proof enough of their grand quality. Messrs. R. P. Ker & Sons of Liverpool surprised everybody—their friends not the least—with the splendid banks of *Amaryllis* they put up, which did further credit to the horticulture of England. It was quite evident that to most of the visitors our contributions of this plant came as a revelation.

Another speciality from England was found in a large group from Messrs. Cannell & Sons of Swanley, who had a collection of beautiful *Zonals*. Some of them seemed to be much to the taste of the visitors, particularly *Comtesse de Morella*, a vermilion with light centre; *St. Cecilia*, a rich salmon; *Nicholas II.*, deep crimson; *Sir J. Kitson*, a purple of huge size; and *Duchess of Marlboro'*, soft rose. The same firm had a number of blue *Primroses*, very charming, but not apparently so much appreciated as they would be by us. And here it may be noted that in British eyes the show was wanting in one noteworthy respect—hardy border and alpine flowers. The eternal *Azalea* rules the sway.

M. E. Pynaert Van Geert received several honours for his Ferns and foliage plants. Novelty and good culture were both to be noted. He

exhibited some excellent specimens, particularly of *Polypodium aureum*, *Gleichenia Mendeli*, *Adiantum concinnum latum*, *Dennstadtia apiifolia* (a gold medal was awarded to this), *Asplenium laxum pumilum*, *Adiantum tenuissimum*, and *Aralia elegantissima* (silver-gilt medal). We ought to see more of the last named, for it has grace and symmetry, with a colour as effective as *Prunus Pissardi* amongst outdoor trees. The De Smet, Frères, exhibited some magnificent Tree Ferns and Palms, towering specimens, giving the imposing green background for banks of bright colour which the Continentals love. Most of the kinds were old friends, but this remark hardly applies to *Latania borbonica aurea striata*, which gives us yellow variegation, like the well-known *Aspidistra*, though not in reckless profusion. A *Todea barbarea*, 6 feet high and through, attracted a good deal of attention, and also a gold medal. *Zamia Lehmanni glauca*, a very distinct and effective silvery form, carried off a silver medal. We could do with it—the plant—here. Mr. Jules De Cock received a medal for the very handsome *Cibotium princeps*, and so did Mr. A. Michiels for *Dracæna fragrans aurea striata*, a plant of fine habit and rich colour.

It is scarcely necessary to say that there were hosts of *Anthuriums*, but there were not many of the quality of *A. Scherzerianum Souvenir de Louis de Smet*. Perhaps it is as well that the number is few while such names are given; but be that as it may, the variety is a gem, having enormous spathes of wonderful colour. As far as excellence of culture is concerned, perhaps Mr. Warocque carried off the palm. He had a large group of plants, each 3 or 4 feet through, and carrying eighteen to twenty fine spathes each. Mr. A. de Smet had, however, a grand group also. The Comte Kerchové de Denterghem showed *Anthurium Hookeri*, with leaves 5 feet long (special medal). *Caladiums* were not up to Laing size, if they were to Laing colour; Mr. L. Van Houtte had, nevertheless, a beautiful group of them, which would probably have received more attention, being well placed near the entrance, if people had not been falling over each other to get to the Orchids.

Florists' flowers were admirably shown by the well-known Parisian firm of Vilmorin. Their *Cinerarias*, both single and double, were excellent strains, and the plants well grown. Their group was fringed by a line of white *Primula obconica*, profusely flowered, and very attractive. The same firm sent a number of *Calceolarias*, hardly so meritorious in type. The name of Cutbush was known at home and abroad for many things years ago, but not perhaps for *Carnations*. The firm contrived, however, to draw many a rapturous "Tiens!" and "Voilà!" with their Ghent group. The sorts were *Malmaisons* mostly, but included a few other forms. *Hyacinths* and *Tulips* were abundant, but, lacking any special horticultural interest, are passed.

The larger of the two main exhibition buildings was referred to by many as a work of extraordinary art in flower grouping. They could not have seen Hamburg. Beauty there was, but it was of the garish order. For instance, of the eight large floor groups, seven were Indian *Azaleas*, and the eighth *Azalea mollis*. It was a huge sheet of dazzling colour, sadly in want of relief. Perhaps the Committee were oppressed with a tardy sense of repentance as regards the reporters, and gave up their splitting tactics. In justice to them, however, it must be recognised that the *Azalea* is of such vast importance as a trade plant in Belgium that it is bound to have a prominent place. Some of the specimens were really wonderful. There were beautiful banks of specimen and fine-foliage plants along each side of the great building.

The *Azaleas* were worth a paragraph to themselves. The principal group was a circular one. More than one exhibitor had contributed to it, but the honours were divided between the Countess of Kerchove and Mr. de Ghellinck de Walle. Truly marvellous were some of the giants of the latter famous grower. They were half globes, 6, 7, and 8 feet across, beautifully rounded and smothered with bloom. In impressiveness, in rich majesty of effect, they eclipsed everything, but in point of horticultural interest they did not exceed the *mollis* forms shown by Messrs. B. Spae, Pynaert Van Geert, and M. Koster. The latter had a number of *mollis-sinensis* crosses, principally unnamed seedlings, but including (the best sort in his group) the splendid yellow *Anthony Koster*. This is a magnificent *Azalea*, and does high honour to the raiser.

If the mixing system was partially deserted with the floor groups, it recurred with depressing severity on the wings. Thus comments become more than ever of a hotch-potch character. The Countess of Kerchove contributed some Cape and New Holland plants, such as *Diosma cordata*, *Chorozema Lowi*, *Kennedya purpurea*, and *Eriostemon floribundum*. *Choisya ternata*, as a pot standard, was not a whit less beautiful than *Deutzia gracilis* near by. Mr. L. Eckhaute, Mr. E. de Cock, and Mr. Louis van Houtte were of the few exhibitors of *Camellias*, which were not a strong feature, any more than *Clivias*. *Adenandra fragrans*, in the form of a bush a yard across, was as noteworthy as anything amongst the pot plants, unless it be an *Eriostemon*, unblushingly labelled *Acacia linearis*. If someone in this country showed pot Oranges like Mr. Van de Wynckal of Ghent, and Mr. Emile Lossy, they would soon be popular, for the little plants were as compact and full of fruit as a Worcester Pearmain Apple. There were very few *Roses*, and those not of a type we like. They were mostly pot standards. On the other hand, *Rhododendrons* from Mr. Pynaert van Geert, Mr. B. Fortie, Mr. Spae, Mr. van Heddeghem and others were by no means wanting.

There were the usual social functions, or perhaps it would be more correct to say—since, judging by the remarks of those who went, there appeared to be some disappointment on that score—that the first day was not quite what it used to be. However, a garden party at Laeken quite made up for it. Being otherwise engaged I was not of the thousand or so of the king's guests. From beginning to end the Journal representative paid his way, and did none the worse for it. If, therefore, the present report lacks something on the score of official guidance, it can at least claim the impartiality which might be expected from the man in the street, who drops in casually, sees what there is to see, and having said his say about the show, from the point of view of the unprejudiced on-looker, hies him home.—W. PEA.

NOTES ON SALADS.

(Concluded from page 307.)

CELERY is not only an important ingredient in the salad, but an indispensable kitchen garden crop, and worthy of the best attention that can be given to it: but here I do not intend going into exhaustive details of cultivation. I will therefore only allude to those points that are of most consequence. The type of Celery best adapted to our purposes is to be found among the short, or medium and compact-growing sorts. These are well represented by Turner's Incomparable, Seymour's Superb White, Sandringham, Carter's Ivory White, Cole's Red Defiance, Major Clark's Red, and Standard Bearer. Several of these have more or less the peculiarity of making nearly all their leaves of one length, and so have little or no waste about them. The Ivory White just named has this quality in a marked degree, and Standard Bearer is the hardiest of all. These dwarf sorts of Celery admit of being planted much closer together and in shallower trenches, and consequently require less earthing up than the taller and coarser kinds. Sowings may be made from the beginning of March to the end of April: the early ones in gentle heat, and the later or last in the open ground. I have already remarked that the quality of salading depends largely upon its being grown freely from first to last, and with Celery this is a point of first-rate importance. Great care should therefore be taken that the young plants sustain as small a check as possible in the one or two removals involved in cultivation. Given a good variety of Celery, I believe that pithy and stringy stalks and premature bolting may invariably be attributed to defective cultivation. Whether planted in single or double lines, in trenches, or in beds with the rows crosswise, Celery requires plenty of manure under it, and a bountiful supply of water or clear liquid manure during early growth and previous to the commencement of earthing up. The earthing must not be begun too soon, and preparatory to that each plant should have the side growths and a few of the small leaves removed, and be somewhat loosely tied round to keep the earth out of the heart, at the same time pressing the soil rather firmly between the plants. A second earthing will be required a few weeks later on, and when growth has nearly ceased a fine dry day should be taken advantage of to perform the operation finally, again taking care to keep the soil out of the heart of the plant. In the spring of the year the remains of the Celery crop may be dug up, and as much of it as is sound laid in carefully on the north side of a wall where it can be protected if necessary. The operation of removal is a check upon growth, and the shady position still further retards it, and thus the Celery season is considerably prolonged.

Radishes require a generous soil, and in hot weather a somewhat shady position. Wood's Early Frame is a good one to sow in gentle heat among early Carrots and Potatoes in February and March, and there is no nicer Radish than the French Breakfast to sow out of doors from March to the end of August. A sowing or two of Black Spanish made late in August and early in September, where they can have a little protection if necessary, are useful in the winter months. When Radishes are required to be dished up by themselves they look much better if, instead of chopping all the leaves off to one length, two or three of the larger ones are removed entire and the green seed leaves left on.

Chicory and French Dandelion sown in drills about the middle or end of May, or even early in June, are quite invaluable for lifting and forcing in a dark place in the winter time. If sown earlier than the time named, these crops throw up their flower stems during the autumn, and are thereby either quite spoiled, or at least much deteriorated.

Beet, when in good order, exactly fulfils the conditions of a salad plant, as it is not only good for food but pleasant to the eye. It thrives best in a light friable soil that has been well manured for previous crops. A good time to sow is from the end of April to the middle of May. The Beet is a tender plant, and if sown too early is liable to be injured, or even killed, by late spring frosts; it is also subject to run to seed, and thus become useless. Small or medium-sized roots that are free from "forks" are the best, and especial care should be taken at the time of lifting to avoid all cuts, breaks, and bruises, as upon this depends the brilliant colour and fine flavour so highly prized at table. Three good sorts to grow are the Egyptian Turnip-rooted, Pine Apple Short-top, and Nutting's Dwarf Red, and there are others equally good.

Mustard and Cress need but few remarks beyond this, that in their treatment we must diverge a little from the good old rule of "sow thin, and sow often," and instead we must sow thickly, and often, and evenly, on a level surface in shallow boxes during winter and spring, and in summer a shady place out of doors will suit them well. The two crops should always be sown separately, and the seed should be kept dark and moist until germination takes place, which will be a little quicker with

Mustard than with Cress. Rape is sometimes used in this way, but it is altogether inferior in quality to White Mustard.

Corn Salad, or Lamb's Lettuce as it is sometimes called, is a useful and easily managed salad plant. It may be sown at any time in good free soil, either thickly, to be cut in the mass like Mustard and Cress, or thinly, to be utilised when the individual plants are big enough. It may also be pressed into service, if needed, by being sown in shallow boxes and brought on in gentle heat.

Rampion is a salad plant not often seen nowadays, and yet it is easily managed by the timely observance of one or two points of cultivation.

FIG. 68.—NARCISSUS LADY HELEN VINCENT.

Several sowings may be made during the spring and early summer in very fine soil. This is an important point both as regards the seed-sowing and the after growth of the root. The seeds are very small and smooth, and the long white Radish-like root is liable to "fork" if the soil is lumpy. The seed is best sown in very shallow drills, and the crop should be duly thinned and kept free from weeds, and well watered during dry weather. The root is the part eaten, and it should be peeled before being committed to the salad bowl to add its sweet nutty flavour to the rest of the appetising compound.

Watercress may be utilised as a salad plant at any time, its peculiar flavour and aroma being always agreeable. Boxes of any sort or size filled with roots planted in ordinary good soil, and placed in a little heat, or even in a cold frame, and frequently and plentifully doused with clean water, will soon give plenty of Cresses.

A green salad, consisting chiefly of Sorrel, Dandelion, and Burnet, may be procured from our meadows during the summer season, and many such are gathered by the foreign workmen resident amongst us. Burnet is said to give the flavour of Cucumber to a salad, and curiously enough the foreigners seem all to know the plant we call Burnet by the name of "Pimpernel," while we attach exactly the same name to a plant which is botanically and otherwise totally distinct, the one being Poterium Sanguisorba, and the other Anagallis arvensis. The mixing of a salad can hardly fail to be of interest to a gardener, even though he is not called upon to do it, and here, as a rule, his interest in it ceases.—H. F.

ANEMONE APENNINA.—The Apennine Windflower is at present in full flower, its blue, rose, or white blooms being very attractive. Although later than Anemone blanda it is a more reliable plant, and stands rougher treatment. Planted in grass which is left uncut until the leaves of the Windflower have ripened, it is very beautiful, and thrives splendidly. Although sought after by some, the rose and white forms are less effective than the dark blue shades. It has sometimes been sent out from some nurseries in place of A. blanda, but no one who has seen the two can fail to recognise the plants. The sooner A. apennina is procured after the leaves have ripened the better.—S. ARNOTT.

“DAFFODIL LAND.”

SOME readers may imagine from the above title that these notes will deal with Daffodils in Spain and Portugal or in the Isles of Scilly. Such, however, will not be the case. The Daffodil Land of which mention is now about to be made is much nearer home; indeed, it is within a dozen miles of our great metropolis. What need is there now to say that the title is applied to the Long Ditton nurseries of Messrs. Barr & Sons? None at all. It is, indeed, Daffodil land, as all travellers on the S.W.R. main line know so well, for there are millions of bulbs producing more millions of flowers. A glorious spectacle indeed is this. The eye wanders over waving masses of golden Daffodils—some large, some small, but all beautiful as well as useful for the adornment of our gardens and homes during April and May. Who does not admire the “nodding Daffodil?” Everyone, beyond a doubt. Then let all who can visit these grounds at once, and they will still be in time to see thousands of flowers of more than passing beauty. The best station to utilise is Surbiton, whence Daffodil Land is about fifteen minutes’ walk.

Though the head quarters of the firm are in Covent Garden, one of the chiefs, Mr. William Barr, can almost invariably be found at Ditton, and a walk through the nurseries in his company is more than interesting—it is instructive. Familiar with the geography of the Narcissus, he can tell where this variety is found; where another was discovered by his father, Mr. Peter Barr, V.M.H.; and what with the conversation and admiring the many varieties, the time will pass all too quickly. A visitor on a recent day had the temerity to ask how many bulbs there were growing in the nurseries. But much as Mr. “Daffodil” Barr knows of his favourite flowers, this was too much for him, though he ventured to suggest somewhere between 2,000,000 and 3,000,000, adding, “but there are too many to count.” Just so, a great deal too many; and we, with most others, would prefer to see and admire the flowers, rather than commence the task of counting up the bulbs.

As an example of the magnitude of the stock held by the firm it may be noted that in one mass there are upwards of 50,000 bulbs of *Barri conspicuus*, and this does not represent more than half the number of this variety alone. True, it is one of the most popular *Narcissi* in cultivation, but the example is a fair one nevertheless, for all others are as large in proportion to their popularity. In all there are 17 acres under cultivation, of which the major portion is devoted to Daffodils, but there are large quantities of *Pæonies*, *Tulips*, and other hardy plants. Though we occasionally hear of disease amongst *Narcissi*, the plants at Ditton are healthy and vigorous, and produce flowers of splendid substance and very rich in colour. It is possible they have never been better than this year in these two respects, and if excellent top growth may be taken as a criterion, the bulbs will be of the best quality when they are lifted. They are all grown on raised beds, the soil of which has been thoroughly worked and is in splendid mechanical condition, as well as abounding in the food that the plants are known by these specialists to require. The spectacle is such as can only be seen in the neighbourhood of the metropolis at any rate once a year, and it is therefore not to be wondered at that so many people find their way to Ditton.

A FEW OF THE CHOICER VARIETIES.

It we take the choice and new varieties into consideration it would be quite safe to say that nowhere can such a collection be found. Others have some of them perhaps, but no one in such numbers as those of Messrs. Barr. These, however, are not in the open field, and to see them we must enter an enclosure where they are comparatively safe from wandering depredators. It is an open question whether the premier position ought to be accorded to *Monarch* or to *Weardale Perfection*—that is to say, of the named varieties, for there is an unnamed bicolor that is distinctly superior to either. Of this more will probably be heard another season when it has been properly tested. *Monarch* is yellow both in the immense trumpet and in the perianth segments, while *Weardale Perfection* (fig. 69) is equally large, but is a bicolor having broad white perianth segments. They are superb—both monarchs of their respective colours. Let no one order rashly of these two, however, for the modest sum of 15 guineas is the catalogue price for one bulb of the former, while the latter can be had for 10 guineas. We are inclined to think that twenty years ago a Daffodil at 10 guineas per bulb would have received scant attention, but now it is not only asked, but readily enough obtained.

Apricot is a distinct novelty, and one which hybridises of *Narcissi* will hail with pleasure, as the trumpet shows distinct shades of red in the yellow ground colour, thus imparting unusual richness to the flowers. The perianth is white, and the flower is medium sized. *Lady Helen Vincent* (fig. 68), which, with the last named, received an award of merit from the Royal Horticultural Society on the 12th inst., is a handsome variety of the style of *Emperor*. The flowers are large, very substantial, and clear in colour, while the habit of the plant is dwarf. A beautiful bicolor is *Victoria*, which may be succinctly described as an

improved *Empress*. The flowers are of great substance, and the bulb is a strong grower. Another handsome variety is *Fred Moore*, of which the broad perianth segments are pale yellow, and the deep, shapely trumpet clear yellow. *Mrs. Walter Ware* is the name of a very attractive bicolor. The perianth is pure white, and the frilled trumpet golden yellow. This variety is a free yet dwarf grower and a profuse flowerer. The stately *Glory of Leyden* is now comparatively well known, as is the showy *Gloria Mundi*, which belongs to the *incomparabilis* section, and is conspicuous mainly by reason of its brilliant orange crown. With *Remarquable* the list of newer ones must close. It is of dwarf habit, and the colour of the broad-mouthed trumpet is very rich yellow; the perianth segments are much paler.

SOME OLDER VARIETIES.

Amidst the host of older varieties there are some that still stand above the remainder, such, for example, as *Emperor*, *Empress*, *Sir Watkin*, *Barri conspicuus*, *Horsefieldi*, and *maximus*, all of which ought to have a place in every garden where *Narcissi* are appreciated. *Golden Spur*, a beautiful form of *maximus*, and *P. R. Barr*, a rather small variety of *Emperor*, must not be overlooked, any more than should bicolor *grandis*, which is so valuable for late flowering. The lovely *Johnstoni* *Queen of Spain* will long remain popular, as will *M. J. Berkeley*, *J. B. M. Camm*, *Michael Foster*, and *princeps*. Of the lighter forms, of which *moschatus* and *cernuus* may be quoted as typical, the best include *Cecilia de Graaff*, *Exquisite*, *pallidus princeps*, *William Goldring*, and *W. P. Milner*, with *Snowflake*, but the later and the first named are rather scarce, and hence the price is somewhat high. These are a few of the many large trumpet varieties that are to be seen in such good condition at Ditton, and all of which are well worthy of a place in every collection.

Of the *incomparabilis*, one has been named as a standard variety—namely, *Sir Watkin*, to which we might advantageously add *Beauty*, *C. J. Backhouse*, *Frank Miles*, *Goliath*, *Queen Bess*, *Princess Mary*, and

FIG. 69. — NARCISSUS WEARDALE PERFECTION.

Autocrat as being above the average of merit. Besides *Barri conspicuus*, *B. Sensation* and *B. Maurice Vilmorin* must be grown; while of *Leedsis*, *Gem*, *Grand Duchess*, *Catherine Spurrell*, *M. Magdalene de Graaff*, *Monnie Hume*, and *Mrs. Langtry* ought not to be forgotten.

And so one might go on enumerating charming single varieties to the exclusion of the doubles, amongst which the common double Daffodil still stands pre-eminent. But we must stop. Those who would learn more or see those mentioned must go to Ditton at once, or the chance of admiring them will be gone for yet another year.—DAFF.

THE JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY

A FEW PICKINGS.

PART 3, vol. xxi, the April issue of the official record of the Society's work appears to be of unusual size, and is certainly of great diversity, while it is undoubtedly of marked excellence. The papers on the progress in "Fruit Culture," in "Vegetable Culture," and in "Market Gardening," from 1837 to 1897, by Messrs. G. Bunyard, A. W. Sutton, and J. Assbee respectively, are worthy of preservation by all who are interested in the important subjects which are treated so thoroughly. As citations were given from these papers when they were read in the autumn, we pass to take a few very brief samples from others.

THE HOUSE SPARROW.

A fuller, fairer, and more exhaustive examination into the value or otherwise to cultivators of this ubiquitous bird has seldom been seen than that of Miss Eleanor A. Ormerod and Mr. W. B. Tegetmeier. They have evidently sought assiduously to elicit the truth, and nothing but the truth. After examination of several witnesses, the sparrow is not pronounced a friend, but an enemy to the farmer and gardener, and ought to be decimated. Here is the summary :—

In the present space it is impossible to enter fully on this important national matter, but still we find, in addition to what all concerned know too well already of the direct and obvious losses from sparrow marauding, that there is evidence of the injurious extent to which they drive off other birds, as the swallows and martins, which are much more helpful on account of their being wholly insectivorous; also that, so far from the sparrow's food being wholly of insects at any time of the year, even in the young sparrows only half has been found to be composed of insects; and of the food of the adults, it was found from examination that in a large proportion of instances no insects at all were present, and of these many were of kinds that are helpful to us or harmless. Also it is well on record that there are many kinds of birds which help us greatly by devouring insects, and that where sparrows have systematically been destroyed for a long course of years all have fared better for their absence; and also attention should be drawn to the enormous powers of increase of this bird, which under not only protection, but to some extent absolute fostering, raises its numbers so disproportionately as to destroy the natural balance.

Here as yet we have no movement beyond our own attempts to preserve ourselves, so far as we legally may, from sparrow devastations; but in the United States of America (on the evidence of which we have given a part) the Association of the American Ornithologists gave their collective recommendation that all existing laws protecting the sparrow should be repealed, and bounties offered for its destruction; and the law protecting the sparrow has been repealed in Massachusetts and Michigan. Dr. Hart Merriam, the Ornithologist of the U.S. Board of Agriculture, also officially recommended immediate repeal of all laws affording protection to the English sparrow, and enactment of laws making it penal to shelter or harbour it; and Professor C. V. Riley, Entomologist to the Department, similarly conveyed his views officially as to it being a destructive bird, worthless as an insect killer.

In Canada, on October 6th, 1888, at the annual meeting of the Entomological Society of Ontario, Mr. J. Fletcher, Entomologist of the Experimental Farms of the Department, strongly advocated the destruction of the sparrow; and, in reply to the Hon. C. W. Drury, Minister of Agriculture (who attended the meeting as head of the Agricultural Department of Ontario), stated "that this destructive bird was no longer under the protection of the Act of Parliament respecting insectivorous birds, and that everyone was at liberty to aid in reducing its numbers."

Reasoning on the same grounds as to procedure in this country, we believe that similar action is, without any reasonable cause for doubt, called for here. The amount of the national loss, by reason of ravaged crops and serviceable birds driven away, may be estimated, without fear of exaggeration, at from one to two millions a year.

We do not pretend to offer suggestions as to what may be considered fitting to do by Government authority, but much of their own protection lies in the hands of farmers and gardeners themselves; and sparrow clubs, well worked, and always bearing in mind that it is *only this one bird* that is earnestly recommended to their attention, would probably lessen the load to a bearable amount; and we believe that subscriptions, whether local or from those who know the desirableness of aiding in the work of endeavouring to save the bread of the people from these feathered robbers, would be money wisely and worthily spent.

EXPERIMENTS WITH TOMATOES.

Mr. W. Neild records a series of experiments with various artificial manures on Tomatoes, and gives good advice on packing the fruits. Mr. Neild seems to have arrived at the conclusion that "potassic manure is of little or no use for Tomatoes." Seeing that the best results in 1896 were produced by the aid of liquid manure from stables; and in 1897 by, in one case, a mixture of nitrate of soda and nitrate of potash; and in the other, by the same ingredients, plus superphosphate of lime, we scarcely think he has proved his case. Persons who are interested in the subject had, however, better read his paper and judge for themselves.

HARDY PLANT BORDERS.

A combination paper by Miss Gertrude Jekyll and Mr. H. Selfe-Leonard ought to be both interesting and useful to lovers of hardy flowers. It is based on the association of selected plants, as shown in diagrammatic illustrations. These differ from any we have seen before, and are decidedly suggestive. As might be expected, the plants chosen include the best, and borders furnished as indicated must have an imposing effect. The paper is proof against "picking;" must be examined to be understood, and there will be no difficulty in comprehending what is so clearly presented.

NOTES ON SOME CURIOSITIES IN ORCHID BREEDING.

Mr. C. C. Hurst's paper on this subject is voluminous and exhaustive. It is something like a monument of investigation, and the records of accom-

plished facts are eminently worthy of the pages on which they are inscribed. We can extract nothing from the essay to fairly represent its character, but we can and do congratulate the author on the excellence of his work.

THE DEPTH IN THE SOIL AT WHICH PLANTS OCCUR.

There is much more in this thoughtful paper by Professor F. W. Oliver than its title would suggest to the general reader. It has the merit of being "fresh," and deals with a subject which is by no means a familiar one to cultivators of plants generally—the contractability of roots. It is explained as follows :—

The special feature associated with root-contraction, with which we have more particular concern here, is the manner in which it leads to the drawing of the whole plant down into the soil. As a root develops it continually penetrates deeper into the soil and comes into intimate contact by means of its root-hairs with the particles of the soil, and as the apical development continues it becomes in time very firmly fixed. When, now, contraction supervenes in the older parts, tensions arise which lead, in the case of roots normally fixed, to a gradual pulling down of the whole plant into the soil. So considerable is this tension that if the root be cut, a space 2 or 3 millimetres across may arise between the two cut surfaces. Three stages in the sinking of a young plant of *Phaedranassa chloracea* into the soil from this cause are illustrated.

The illustration referred to is very interesting, and not less so is another showing the dragging down of the tubers of *Arum maculatum* by the contractability of some, but not all of the roots, and hence the position of the tubers within the soil. The Professor concludes :—

I have attempted to bring together the main facts which have been ascertained—largely by Rimbach, Stroeve, and de Vries—in connection with the various means employed by plants in reaching their normal level in the soil. Owing to the difficulties attending continuous observations upon the subterranean parts of plants our knowledge is still much at fault, whilst the conditions under which many of the phenomena are exhibited are unknown. It is because the practical horticulturist has such unrivalled opportunities for studying these little-known phenomena in numberless instances that I am glad that the facts set forth above should appear in the Royal Horticultural Society's Journal.

HORTICULTURAL EXHIBITIONS AND SCHEDULES WITH THE PRINCIPLES AND PRACTICE OF JUDGING.

Very different from the foregoing is this paper by Mr. J. Wright. It is based on experience, and covers a wide field. Many familiar subjects are dealt with, and some that are not familiar to all cultivators and exhibitors. For instance, the working of what is termed the "Point Value" system of judging is made clear, and the origin and history of groups arranged for effect published for the first time. As is stated, the essence of the "point value" system of judging is based on the principle that every point or mark of merit accorded is of *equal value* (as it is), and can be represented in money. The precise amount is easily determined, and shown. The amount of necessity varies according to the total sum allocated, and the number of points accorded to the produce in competition. In Kent, a "penny a point" is allowed for allotments, and has proved so satisfactory, as tested in upwards of 200 instances, that the new plan is now called the "fair plan" by hundreds of men. The author goes on to say :—

Having given an example of the working of the "point value" system in which the prizes were very numerous, but small (as in the Kentish instances) it seems desirable now to test the plan where the prizes are high, and the classes and competitions of a national character. An opportunity is afforded for doing this by tabulating the prizes that *were* awarded in the orthodox way, and those that *would have resulted* if the "point value" system had been in operation in the two great classes at Shrewsbury last year. Here is an example :—

DECORATIVE DESSERT TABLE CLASS (Shrewsbury, 1897).

Societies' Prizes awarded.	Points recorded, ascertained value 1s. 11d. each.	Aggregate "Point Value," excluding decimals.
£ s. d. 1st 12 12 0 2nd 12 12 0 3rd 8 8 0 4th 5 5 0	105½ 104½ 99½ 96½	£ s. d. 10 2 2½ 10 0 3½ 9 10 8½ 9 4 11½
£38 17 0	406	£38 18 2

The reason of the money value of the Society's first and second prizes being equal was the addition of £5 with the Veitch medal to the first prize.

Taking no account of this, but regarding the addition as an award of honour won by one point, advocates of the "point value" system would say that the

1st prizewinner had	<i>above</i>	his just due	£2 2s. 9½d.
2nd	"	" <i>above</i>	" £2 11s. 8½d.
3rd	"	" <i>below</i>	" £1 2s. 8½d.
4th	"	" <i>below</i>	" £3 9s. 11½d.

If the total amount allocated in the schedule could not be exceeded by 1s. 2d., it would only be necessary to deduct 3½d. from each of the prizewinners to insure an exact division of the £38 17s.

Difficulties, disqualifications, and incidents in judging are dealt with in the paper.

CHRYSANTHEMUM SPORTS.

The comprehensive essay by the Rev. Professor G. Henslow will be read with avidity by many growers of the Autumn Queen. The nature of sports is ably discussed, and long lists of examples given. The subject is

treated scientifically and practically in its various aspects ; but the problem is not solved, for the talented author says :—

If we ask what causes all these differences to arise respectively, at present there is no reply, and therefore we do not know what steps to take to induce them to form respectively, until Nature herself has supplied the first indication of a change. The first thing to do, if we want to discover a cause, is to look out for coincidences. If a sport appear, I would ask the florist to note anything and everything he can observe as to the conditions surrounding that plant, and to find out its ancestry. It would seem desirable to note also the climatic conditions at the time, as sports of a like kind in plants, as we have seen, often appear simultaneously both in different places of the same county or counties, and also in different seasons. It is only by accumulating coincidences that we can arrive at the first suspicion of a cause. When we think we may have discovered that a certain result seems to occur often or generally under certain particular circumstances, then is the time for experiments, to try and induce the same result to occur by artificially supplying those circumstances. Practical men are often inclined to look suspiciously on scientific men as being too theoretical ; but the reply is, that if only practical men would observe more, and record their observations, and then hand them over to the scientist, each party would, without doubt, benefit very largely by the other. The scientist has no such grand opportunities as the practical man. Thousands of facts familiar to the latter would be inestimable boons to the former, if only he could get at them. The practical man, unfortunately, does not always perceive their significance, but if every sport that has occurred on *Chrysanthemums* had been recorded, coupled with the whole history of the plant and description of its surroundings, the method and kind of soil used, &c., we should probably have known much more than we do now, as Dr. Masters suggests, who thus wrote :—"Whoever will investigate the cause of these sudden outbursts of local variation must, of course, sedulously examine each case for himself, according to the measure of his ability and of his opportunity. The circumstances, the history, the progress, the anatomy of each particular sport must be investigated, both absolutely and in relation to similar outgrowths in other plants. Until this is done, and it has not been done yet, any explanation as to the cause of the phenomena must be a matter of speculation." Could these admirable recommendations be carried out, I might perhaps at this moment have been holding forth on "The Causes of Sports, and How to Produce them," instead of being compelled to expose my ignorance by saying that neither I nor any botanist, as far as I know, can yet fully expound the "why" and the "wherefore" of bud variation.

All will hope that Mr. Henslow will yet have the opportunity for "holding forth" on the text he suggests, and which few indeed could treat so well.

We consider the entire issue well worth the charge that is made (5s.) to those who are, unfortunately, non-Fellows of the R.H.S. Those who are enrolled have it for nothing.

THE PLETHORA AND PROSPECTS OF GARDENERS.

It was with very great interest that I read the remarks of "An Old Provincial," on page 307. Like himself, I think it is sad to see the number of gardeners, ever on the increase, seeking situations through our journals alone. We know that vacancies are very few in comparison, and that a large number of good gardeners are crowded out through the numbers being so great, and I fear that it will continue now that the premium system is almost done away with.

Knowing these things one is filled with wonder when one hears of the modern woman taking to our vocation, for which, in my opinion, she is quite unsuited. I should like to know if she goes through all branches of training as a probationer, which, if she is to be practical and capable of managing a gardening establishment, she must do. I can seem to picture her making a Mushroom bed on the top tier of our Mushroom houses, stoking the furnaces late at night as occasion may arise, and scores of other unwomanly duties, known only to our fraternity, which to make a practical gardener must be learned. Perhaps I shall hear that she starts at the top of the tree and leaves these duties to others, and if such be the case I think she will keep few situations from the man who has worked his way up from the shed.

Women servants are in demand all round us, and their remuneration is quite as good as those in the garden, while the work appears to me to be much more suitable for her. In a florist's show house she does well, but as a gardener she is a mystery to me.—G. M., *Sussex*.

If a ballot could be taken of the articles appearing weekly in the *Journal of Horticulture*, as to which were read with greatest interest by hundreds of young gardeners, I have no hesitation in saying that those referring to the prospects of gardeners would come out at the head of the poll. It is doubtless the worthy intention of those correspondents who write on this subject to give good advice to the rising generation of gardeners, and these should feel gratified to know how great is the interest taken in their welfare. At the same time, he who offers advice to young men, which if taken may alter their course of life, assumes a great responsibility, and unless he has the best of reasons for what he says he should hesitate to advance opinions which may have results that he does not foresee.

Everyone who understands the matter will agree with the opening sentiments of "Onward," on page 204, but does he not let his enthusiasm run away with him in the concluding paragraph? where he advises young men "not to be led away by the glamour of appearances connected with many private gardens, but if they have energy and brains to get into one of the finest schools of horticulture in this country or the world—viz., a great market establishment." True, the statement is qualified, and

assuming that the majority of young gardeners are blessed with energy and the average amount of brains, what would be the result if "Onward's" advice were generally followed? There would be a wholesale migration from private establishments, and a consequent flooding of a branch in which there is ample room for improvement in the way of shorter hours and increased pay. Your correspondent concludes as though he had solved the problem after giving the foregoing advice. There are doubtless openings for ability in the trade, as also there are in private service, but the facts of the case seem to be that it is a question of supply and demand, and the former is double that of the latter.

Mr. Street, on page 284, approaches the matter from the point of view of a private gardener, making suggestions from which improvements might accrue without taking drastic measures. I presume that your correspondent's idea is to adopt means of checking the output of gardeners, though he has not made the way quite clear. Suppose that to every head gardener in good establishments there are half a dozen juniors. They are all aspiring to the one position, therefore the chances are six to one against them, and assuming that the best come to the top, there must be others with the average ability who have to be satisfied with a lower place. As long as this is so the difficulty in obtaining head places will always be present.

Perhaps, with a little sifting and more discussion, Mr. Street's idea of forming an association might be helpful. He appears, however, to have omitted any mention of the most important section—viz., the employers. The majority of head gardeners' positions now-a-days are filled through the personal influence of friends rather than the recommendation of gardeners, and probably this is why the best men are not always found in the best places. Would the formation of a committee obviate this? If so, then the sooner it is formed the better; but I doubt it. As long as there is no special qualification to be obtained before a man can call himself an accomplished gardener the trouble will remain; and, even then, would employers confine themselves to engaging only those men who possessed the necessary qualification? Without the coalition of those holding the purse-strings I fail to see the advantages accruing from an association such as your correspondent suggests.

"Reform," on page 290, protests against the custom of paying premiums—and rightly so, unless there are some advantages to be obtained from it. Anyone paying a premium expects in return to be taught a trade or profession, and when his apprenticeship has expired he is supposed to be competent. If this were so, then a young gardener, after paying for his learning, should be efficient when his time expires. But it is not so. He pays a premium to learn the rudiments of his calling, and then has to go through a course of training in several other establishments before his gardening education is completed. If the custom of paying premiums were a general one, perhaps there would not be such an over-supply of gardeners; and if such payment would insure, or even assist, in the obtaining of a suitable situation, there would be no cause for complaint; but I wonder how many present-day gardeners who are holding the best positions in the country paid a premium to commence with. One thing I know, there are many who did not. The guiding spirit of the *Journal of Horticulture* has always shown sympathy with gardeners old and young, and would like to see them all happy; the methods of training is a subject of more than passing importance in leading to that desirable end.

The three correspondents quoted have approached the matter from different standpoints; but is there not another? Could not a great deal of work that is done by young men in training for gardeners, be done as well by local labour—men not in training for professional gardeners, but as worthy garden workers? If this is so, would not a better class of local workers be raised, men who would be perfectly content as such, with a corresponding reduction in so-called trained gardeners jostling against each other for filling vacancies which are so few and far between? True, an occasional bright, energetic worker might force himself upwards and onwards by sheer merit. By all means let him do so. By the present system of making gardeners are there not hundreds of young men who are neither particularly devoted to their duties, intelligent, studious, or energetic? There are far too many of them careless, thoughtless, and not a few reckless, more given to sport than to work, yet some of these by accident or favour crowd out intrinsically better men, and lower the status of British gardeners.—EX-FOREMAN.

FRUIT BLOSSOM.

THERE is a prolific display of Plum blossom at the present time. Green Gage Plums have not had so fine a show of bloom for years. Victoria Plum trees last year produced little blossom and less fruit. It is exceptional for the latter to fail in fruiting, but the trees claim a rest sometimes. This season they are blooming freely.

Pears also are exceptionally loaded with bloom. Williams' Bon Cbrétien failed last year to bloom, and there was only a poor crop of Louise Bonne of Jersey. Both these varieties, however, are blooming well this season.

Bigarreau Cherry trees promise well for bloom. Last season was a very poor one. Morello Cherries are furnished well. Last year the crop was nil. This seldom occurs with these free bearing trees. At the time of writing Cherries are not in bloom, but a few days will bring them on.

On the whole, there will be a good display of Apple blossom shortly. Blenheim Orange failed to bloom last year, but this year there is an abundant promise. The same may be said of Wellington, Keswick Codlin, and Duchess of Oldenburg as regards bloom. Last season these varieties produced good crops.—E. D. S., *Gravesend*.

THE YOUNG GARDENERS' DOMAIN.

YOUNG GARDENERS' PREMIUMS.

THE above was really the gist of an article by "Reform" in the *Journal of Horticulture* for March 31st, page 290. I can recollect a number of places where from six to a dozen young gardeners are employed, and in each case, when a vacancy occurs, and the engagement of an experienced hand seems desirable, preference is given to a youth with a small premium to fill it. "Reform" also tells us that the teaching of young gardeners is a duty largely devolving on the foreman. No doubt this is so, but I do know of two gardeners who take interest in their young men, and who endeavour to teach and assist them. However, I think this premium-paying is, generally speaking, in need of amendment.—A. H., *Stuffs*.

LACHENALIA TRICOLOR.

LACHENALIA tricolor is one of an exceedingly pretty family of Cape bulbs belonging to the order Liliaceæ. The dark green Orchis-like foliage is spotted with dull purple, and makes a grand contrast to the handsome spikes of orange, green, and yellow flowers. These plants were thought a great deal of formerly, and there are some people who still highly appreciate their beauty. But there are many who are without them, which is a great pity, as they are exceedingly valuable grown in 5-inch pots or baskets for early flowering. If the flowers are required as early as Christmas the bulbs should be potted in June in a compost consisting of three parts good loam, two parts leaf soil, and well decayed manure with a little sand added. They should be grown in a cold frame until about the middle of October, when they may be placed in a moderate temperature. They do not like much heat. If a succession of flowers is required a couple more pottings should be made at intervals of about three weeks. Water must be gradually withheld when the foliage begins to show signs of decay, and when they have quite gone to rest place them in a cool place until the time for repotting comes round. If the pots are placed on their sides so that no water can enter, a very good place to keep them is under the stage in a cool house.—S. S., *Lockinge*.

A GRUMBLE.

"EXCELSIOR," on page 311, remarks that he was at one time impressed by the scarcity of the thoughtful and scientific class of gardeners. Apply that to the young men, as a body, and I agree with him. Since I have been foreman I have not been favoured with a journeyman capable of potting or watering plants in an intelligent manner. I have had several assistants under me who had been, to my surprise, well recommended. There ought to be some test of ability, such as compulsory examination of young men before they are launched on the market as journeymen. A number of young men who pay premiums to go into a large garden for three years, and are then sent out to take charge of a range of glass, are unequal to the duties involved. My experience of several of them is that they are better suited to serve behind a shop counter than to work in a garden, where they seem to dread the soiling of their hands. It is not such men who are required in a garden, but men not afraid of work, either rough or otherwise. Doubtless these remarks will raise the ire of some of the dandies if by chance they find time after the perusal of "Sporting Life" to look into the pages of the *Journal of Horticulture*. I am proud of some of the more promising, like "Semper," "Excelsior," and "Nil Desperandum," and should like to see more follow their example, while if I had an equally able pen I would endeavour to do likewise.—GRUMBLER.

[Why is not the pen of this good "grumbler" equal to those of others that he seems to envy? Is it not his own fault? Without doubting his zeal and usefulness in the garden, he has much to learn educationally, and should learn it before he can hope to win a high position by the test he proposes (examination) in the ranks of accomplished British gardeners. Absolutely as the result of perseverance and success in self education, not unconnected with the *Journal of Horticulture*, a particularly able gardener has just received a valuable Government appointment; but however skilful as a workman, that alone could not have secured him the position.]

NORTHUMBRIAN WILD FERNS.

WILD Ferns grow in great abundance in the Northumbrian moors, crags, and woods, and in summer it is a pleasure to go out hunting for specimens. The Brake Fern (*Pteris aquilina*) the only British species, is very common, often attaining the height of 3 to 4 feet. The plants look very beautiful in summer, until the frost comes and cuts them down. The roots are long and strong, sometimes penetrating as far as 6 feet down in the ground. The Male Fern (*Lastrea Filix-mas*) is called by this name because of the robust appearance of the plants. The fronds are densely scaly, and grow from the centre of the tuft to the height of 3 feet, broadly lance-shaped. In a sheltered position they remain green all the winter, and are very useful for rockery work. The prickly-toothed Buckler (*Lastrea dilatata*), more spreading in habit and of a smaller form, is plentiful. In the shade of the wood is to be found *L. montana* sparingly. The fronds are from 8 inches to 1 foot in height. It has a pleasing effect in garden rockworks, and enjoys a moist shady position. The Hay-scented Fern (*L. cœmula*) is of moderate size and drooping habit. The plants are rare in some districts, while *L. spinulosa* is plentiful, and known by its red-coloured stem. The Lady Fern (*Athyrium Filix-fœmina*) is to be found wherever you go, and makes a good companion for the Male Fern.

The hunter in his search for the Moonwort (*Botrychium lunaria*) has to look very carefully amongst the short grass, for being of the same colour it is rather difficult to find, as it is so small. It is easily known by

the two distinct fronds, one of them being fertile, and grows between 2 and 3 inches high. The Adder's-tongue (*Ophioglossum vulgatum*) resembles the Moonwort, and is often found in a damp field, growing to the height of 4 inches; it is easily cultivated in pots or shady parts of the garden. The Wall Rue (*Asplenium Ruta-muraria*) is a Fern of dwarf habit, to be found growing in old walls and rocks. The largest fronds I have seen are about 3 inches long. In one place I saw a wall about 80 feet long and 7 feet high completely covered with this distinct Fern. *Asplenium Trichomanes* or Maidenhair Spleenwort is a pretty little Fern, known by its dark stem. I have not seen much of the Green Spleenwort (*A. viride*), the few found on the rocks being only 4 inches high. *Asplenium marinum*, an attractive evergreen Fern, is also found on rocks on the coast; the fronds are from 4 to 6 inches in length. It is not very plentiful, as the visitors make a point of taking the roots away. Another of our evergreen *Aspleniums* is the *A. Adiantum nigrum*; when found in old walls and rocks the fronds are from 3 to 4 inches in length, but in shady hedgebank they are a foot in length.

The Scaly Spleenwort (*Ceterach officinarum*) is a dwarf, distinct looking, but pretty Fern; the fronds are thick and fleshy, the upper surface rich green, while the under surface is covered with rust-coloured scales. It is rare; I have only met with it once, and there are only about three plants to be seen; the fronds did not exceed more than 3 inches in length. The Hart's-tongue (*Scolopendrium vulgare*) is a very common plant, and its shining bright fronds contrast boldly with the feathery aspect of the more common Ferns. It inhabits old walls and woods. *Blechnum Spicant*, or common Hard Fern, is one of our native kinds, which produces both fertile and barren fronds. The Bladder Fern (*Cystopteris fragilis*) grows from 4 to 6 inches in height. *Polystichum lonchitis* is represented, while *P. angulare* and *P. aculeatum* are found in abundance. *Allosorus erispus*, or Parsley Fern, is abundant on the Cheviot Hills; *Polypodium vulgare*, growing on crags and mossy banks, is well distributed over the county; while *Polypodium phegopteris* and *P. dryopteris* are rare, though found in a few localities.—PONICA.

HARDY FRUIT GARDEN.

Disbudding Apricots, Peaches, and Nectarines.—Frequent and light removals of ill-placed and other superfluous shoots is necessary at the present time in following the best and most approved system of management. The operation is carried out gradually, so that no severe check is given to the trees by the sudden removal of a large quantity at one time. The weather, as well as the condition of the growths, governs to some extent how disbudding should be carried out.

During a cold period very little progress is made by even the most forward shoots, and disbudding may, as a rule, be discontinued until a warm period again sets in. On well trained trees the shoots which are required to be left for furnishing are those best placed in all instances, whether on the upper side of branches, or situated on the front. The shoots on the under side may, generally speaking, be considered superfluous, while growths at the back of branches and near to the wall or fence are obviously ill placed for training. Of those which are properly placed a rigid selection of the best must be made, so as to prevent overcrowding in the immediate future, when the growths have advanced and the foliage enlarged.

The main objects of disbudding trees on walls are to prevent overcrowding and an undue strain upon the trees, to tolerate no inconveniently placed shoots, and to provide a similar number of succession growths for taking the place of the present season's bearing shoots, which will subsequently be removed. In disbudding rub or cut off the strongest first, and as these are usually situated in the upper parts of the branches, commence in those positions, first dispensing with the shoots behind the branches, then the most awkwardly placed in other parts, finally thinning out the rest. With Apricots a few of the best fore-right shoots may be shortened to three leaves for forming spurs. Peaches and Nectarines bear, as a rule, best on well-ripened young wood of the previous year. The fruit-bearing shoots must have careful attention, securing for each a succession shoot at the base, and a leader at the extremity, the latter for attracting sap to the fruit.

Disbudding Plums and Cherries.—Special attention ought to be given to young trees, as they make numerous and strong growths, which must be thinned and regulated in good time, in order that a proper foundation and shape may be laid. Plums to be and continue fruitful require to be renewed frequently with young growths, which bear freely when two years old; therefore shoots and branches above that age on walls may annually be cut out, their place being taken with young extensions. When Cherries bear well on spurs it is advisable to encourage this system, but failing to do this a judicious annual laying in of young wood may produce more satisfactory results. Disbud Morello Cherries similarly to Peaches and Nectarines, though a larger number of growths may be retained.

Disbudding Apples and Pears.—Established trees trained on walls may be disbudded freely in order to reduce the usually large number

of growths which crowd the spurs. Young pyramids and bushes in the open will also be better for timely attention in the work of disbudding, thus early dispensing with unsuitable growths. The result will be that those retained will develop stronger and grow more freely than when having to compete with a host of others.

Outdoor Figs.—Figs on walls should be trained thinly, the leaves being large, and requiring much room. The crowding of shoots does not benefit the trees, hence any old or ill-placed growths may with advantage be removed. The shoots retained ought not to be shortened, as the fruit is borne towards the extremities of the growths.

The present month is the best for planting Figs, selecting one-year-old trees for the purpose. A friable loamy soil that is known to be of a calcareous nature, and not too highly charged with organic matter in the shape of manure, should be prepared, and the whole made firm before planting. The subsoil should be naturally well drained.

Assisting Newly Planted Fruit Trees.—Extended periods of dry, sunny, and windy weather during spring are frequently very trying to newly planted fruit trees against walls, and sometimes in the open. It is not advisable to saturate the soil too often with water, which cools the particles and renders the formation of new roots in it a slower process. Of course water must be given to fender soil moist enough, but use every endeavour afterwards to conserve the moisture present by affording a light mulching of flaky manure or leaf soil. During the driest periods frequently syringe the trees, which is better than drenchings of water at the roots, for the purpose of aiding a healthy growth.

Watering Established Trees.—Lack of moisture in the soil during the present and succeeding month is frequently the cause of early insect attacks, aphids and red spider being especially prevalent on trees that may be dry at the roots. It is not only the lack of moisture, which is itself a form of food, but inability of the rootlets to gather other food when water is not present in the soil to dissolve and make available the necessary constituents. To such trees, therefore, that are known to be dry at the roots apply water copiously, and follow by mulching the surface.

FRUIT FORCING.

Cherry House.—Directly the stoning is completed the fruit commences colouring, and takes its swelling for ripening. The temperature may then be raised, but it must not exceed 65° by artificial means and 55° to 60° at night, with a little ventilation, increasing it at 70°. Subject to leaving a little air on constantly at the top of the house, close at 70°, but the temperature must not be allowed to exceed that degree in the early part of the day without full ventilation. From the commencement of colouring until the trees are cleared of their fruits syringing must cease, or the fruits will crack, but good moisture should be maintained. Aphides must be kept down by an insecticide, but only fumigation or vaporisation with tobacco or nicotine can be had recourse to after the fruit commences ripening. The border must not lack moisture, and liquid manure should be liberally accorded to trees in pots.

Figs.—Earliest Trees in Pots.—The fruits of the very early varieties are ripe, while later varieties are nearly so, hence the supply of water at the roots must be diminished, discontinuing syringing, and affording a free circulation of warm air, leaving the top ventilators open at night. Although watering is advised to be lessened during the ripening of the fruit, the soil must be kept moist, for this, with moderate moisture in the atmosphere, is essential to the health of the foliage. As soon as the first crop is cleared off the trees syringe them twice daily, renewing the top-dressing, and supplying the roots with weak liquid manure. If the second crop be very abundant the fruits must be thinned, leaving those at the base of the shoots, for it is important not to overtax the trees for early forcing next season.

Early-forced Planted-out Trees.—The trees must now have plentiful nutriment. If the soil require moisture give a thorough supply, and mulch with partially decayed rather lumpy manure. Do not cease syringing until the fruit commences ripening, avoiding then a superabundance of moisture about the house, and provide a free circulation of air until the fruit is all gathered.

Vines.—Early Forced.—To Vines with the Grapes colouring afford a thorough watering, and mulch afterwards with well-sweetened horse droppings. This refers to the inside border. Where the Grapes are fully ripe a reduction of temperature is advisable, yet not below 60°, and affording moderate moisture for the benefit of the foliage. The moisture will not do the Grapes any harm provided the air is changed by free ventilation, admitting a little air constantly.

Succession Houses.—Attend to stopping and tying the shoots. Where the space is restricted stop the growths two joints beyond the fruit, and as foliage is necessary leave the laterals on the stem, both above and below the bunch. Pinch these at the first leaf, especially the basal ones, also above unless there is space for development, when the laterals may be allowed to make two or three joints, but no more growth must be encouraged than can have exposure to light and air. After the space is fairly furnished keep the growths closely pinched to one joint as made. Where there is more space stopping will not take place until growth has extended four or more joints beyond the fruit, pinching the shoot at the joint when the leaf is about the size of a penny. The great evil is overcrowding, which deprives the foliage of the essential light and air, and restricting the growths is intended to prevent that.

Routine.—The tying of the shoots into the places where they are to remain during the summer is an operation demanding much attention. It is a common practice to commence tying down the growths as soon as they are long enough to bend. This is not advisable except as a precaution against injury from frost or scorching, as the shoots at this stage are so tender that the slightest twist the wrong way breaks them. It is a

better plan to defer tying down until the shoots are less sappy, which may be when the fruit is forming; but a better practice still is to so dispose the rod that the shoots, instead of having to be brought down to a nearly horizontal position, will have an incline upwards, yet sufficiently outwards to admit light to the basal leaves of the growths.

Afford Muscats in flower a free circulation of rather dry air, and a temperature 80° to 85° or 90° by day, falling to 70° or 65° at night, raising the points of the bunches to the light, and liberate the pollen at midday by gently rapping the footstalks of the bunches. If there is a deficiency of pollen take it from those that afford it plentifully, as Black Hamburgh, Foster's Seedling, and Alicante, and apply it to the shy setting varieties with a camel-hair brush, previously removing the "caps" by a gentle brushing over of the bunches.

Thinning Grapes.—Where there is a quantity to be thinned commence as soon as they are out of bloom with the free-setting varieties, such as Black Hamburgh, and some, like Gros Colman and Gros Guillaume, may be thinned whilst they are in flower. Muscat of Alexandria, Lady Downe's, and Mrs. Pince, however, must not be thinned until the properly fertilised berries can be determined by their taking the lead in swelling. Follow it up early and late, and on dull days. Surplus bunches may be removed boldly, as overcropping is alike fatal to well-swelled berries as to colour and finish, also next year's crop. Feed swelling crops liberally, either by surface dressings of the approved advertised fertilisers washed in or liquid manure, and maintain a moist genial condition of the atmosphere.

Young Vines.—Those planted last year are breaking naturally, and may be assisted with gentle fire heat in cold weather. The canes will have been depressed so as to cause the buds to break regularly down to the basal ones, when they can be tied in position. Disbud, leaving the best shoots about 18 inches on both sides of the cane or (now) rod. Crop very lightly, one or two bunches being the maximum. Any extra strong Vines planted to fruit early, and afterwards to be cut out, may carry a bunch on every side growth, but six to eight bunches, according to their vigour, are more satisfactory than a greater number to a Vine.

THE BEE-KEEPER.

SPRING MANAGEMENT.

SUCCESS or failure in bee-keeping depends greatly on the spring management, and as no two seasons are exactly alike bee-keepers must be governed by the strength of their stocks, the state of the weather, and when honey is likely to be obtained in abundance, before deciding on what is necessary to be done in the apiary. It is, therefore, impossible to lay down any hard and fast rule, as it would probably only end in failure. If we make a comparison between the present season and a year ago, it will be at once apparent that different treatment is necessary. At the present time the majority of our stocks are in good condition—indeed, we do not remember them being in a more forward state at this early date; whereas a year ago they were quite the opposite. They then required careful management before they were of the desired strength to store a surplus.

Colonies that are headed by young fertile queens, and which went into winter quarters with a numerous progeny of young bees, were well supplied with stores early in the autumn, will not require feeding, as the fruit trees will soon be a mass of bloom. But where several stocks of bees are kept we invariably find some that require attention. It is not advisable to handle the bees or to lift the frames out of the hives unless there is a good reason for doing so, as it is impossible to do this without lowering the temperature of the hive. This should be guarded against, as it may result in chilled brood and its attendant evils. Neither is it advisable to remove any of the coverings, as beginners are sometimes tempted to do when a spell of fine weather sets in, as from experiments we have made we are strong in the belief that it would be a decided advantage to provide extra coverings throughout the early spring. If anyone has any doubt on the matter let them closely observe the difference between two colonies of equal strength, one of which has a quilt and, say a couple of thicknesses of carpet or some warm material, and the other half a dozen warm coverings, on the top of which a piece of board is placed. On examination the latter will be found several degrees warmer than the former.

FEEDING.

From the above it will be seen that warmth is essential. It is, however, of little effect if there is a shortness of stores in any of the hives. Although the past winter has been exceptionally mild, there has not been an increased consumption of stores. This is the more remarkable, as in previous mild winters a much greater number of stocks required feeding at this date than at the present time. How is this to be accounted for? Chiefly, we believe, to the fact that after they were fed up to the desired weight rather earlier than usual last autumn, a spell of fine weather set in, and as there was a great wealth of flowers in all directions which succeeded the rains after the

exceptional heat in July, the bees were able to store an extra supply of natural stores, from which they are now deriving benefit.

If feeding is necessary they may now be supplied with thin syrup in the evening made in the proportion of 1 lb. of sugar to one imperial pint of water. It may be prepared by boiling it until the sugar is dissolved. If only a small quantity is required it is not necessary to boil it, as boiling water poured on the sugar and well stirred will answer the same purpose at this season. Whatever feeder is used it should be one that does not allow an escape of heat from the brood nest. We prefer the system of feeding on the top of the hive in preference to placing it underneath the frames, as in the latter case, if the syrup is not cleared up before morning, the bees from the other hive will find it out and thus cause robbing; whereas in the former, if the feeder is well covered up, no robbing will take place, and if the syrup is given warm (which it always should be at this season), it will be all carried down into the hive before morning.

One of the simplest and most inexpensive feeders is an ordinary honey jar. Tie a piece of thin muslin over the mouth, cut a hole through the quilt the same size, and insert a piece of perforated zinc. This will prevent the bees escaping or being disturbed when refilling the bottle. Place the bottle mouth downwards over the zinc, and the bees will take the syrup readily without an escape of heat from the hive.

PERFORATED ZINC FLOORS.

Are perforated zinc floors an advantage? We are inclined to reply in the negative. At certain seasons of the year they may be an advantage, but from this date onwards for a few weeks we think warm solid floor boards are better. We have several zinc floors in use, but the bees in the hives under which they are placed are not in any better condition than those having solid floors; and as we think the brood nest will be warmer in those hives having solid floors now that breeding is going on apace, we shall take the first opportunity of removing the zinc, or placing a board underneath until more ventilation is required.

During the winter they have hitherto answered admirably, as there is always a circulation of air underneath the frames when they are in use, and if by chance moisture permeate through the sides or roof of the hive, the interior will always be found drier when they are in use than if it is a solid wood floor. Hives that are already fitted with ordinary wood floors need not be replaced with zinc, as ventilation may always be provided by opening the entrance the full width, or by wedging the hive half an inch off the floor board. This we have done with complete success.—AN ENGLISH BEE-KEEPER.

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8, Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Carpet Bedding (H. G.).—We do not know of any work now in print besides the one you mention. Carpet bedding is not nearly so popular as it was some years ago. Close low growing plants are now chiefly used for covering the ground, taller flowering or fine-foliaged plants being inserted thinly, so that each may display its individual beauty instead of growing into a dense mass.

Current Garden Literature (W. Smith).—Sound and reliable information—not the effusive vapourings of sensation mongers—has been given in the columns of the *Journal of Horticulture* on every subject mentioned in your letter, and will be again. It does not follow, for obvious reasons, that every reader finds exactly what he particularly wants to know in each issue, but he has only to state clearly his requirements and the means for attaining the object in view, to be furnished with such guidance as is applicable to the particular case. You are at liberty to test the matter by making your desires and cultural conveniences clear for the cultivation of any kind of plant, or the production of any kind of crop, on which you most desire early information.

Cucumber Plants with Large Leaves, &c. (A. D. H.).—The large foliage and thin stem, with the internodes long, may be due to the forcing nature of the compost—three parts well-chopped turf and one part short peat moss manure, nearly all horse droppings. They are very green, and, as you say, have too much nitrogen. The best thing to use would be equal parts of bone superphosphate and wood ashes, using 4 ozs. of the mixture per square yard. The mixture, which should be dry and crumbly, will tend to stiffen the plants, and promote fruitfulness. We have found it answer remarkably well with both Cucumbers and Melons. If the roots are on the surface use the superphosphate with an equal quantity of loam, and better apply too little than too much, not exceeding the 4 ozs. per square yard.

Birds and Fruit Buds (Lancashire Subscriber).—Your letter has reference mainly to Gooseberries, but the samples you send appear to be of Black Currants, and very poor samples they are. Had they been packed in a little green grass or a soft green leaf, and not misdirected, they would have arrived in much better condition, instead of being practically dead, with not a vestige of green about them. See instructions for packing below, and the correct address above. It is impossible to say "if an insect in the bud is the cause of the action of the birds," as there were no buds to examine. All had either been eaten by birds or dried up and rubbed off in transit. If the buds of the Black Currants were swollen, they were infested with a ruinous mite (*Phytoptis*), and nothing can be applied to reach the enemy within the buds. Whether the birds take the buds because of any insects there may be in them or not, the results are the same, as it is simply a question of no buds no fruit. Bullfinches are most destructive among fruit buds, even a pair of these birds often doing great damage. Sparrows when in flocks often make almost a clean sweep of the buds on Gooseberries. Tits are also destroyers of fruit buds, but are usually less destructive than bullfinches and sparrows. If you can net the bushes against birds in spring, by all means do so. We have seen thousands of buds saved by dashing newly slaked lime all over the branches in spring, when they were wet with dew. The lime adheres, and the birds do not like it. It must be done promptly on the first attack. Old "dead" lime is of no use. A first-rate authority recommends the following as still more effectual:—Take of fresh quicklime, 5 lbs., choosing the lightest lumps; flowers of sulphur, 10 lbs.; water, 10 gallons. Boil half an hour, keeping well stirred; then slake $7\frac{1}{2}$ lbs. each of quicklime and common salt in boiling water, adding to the above mixture also enough water to make 30 gallons. Strain through a hair sieve, and spray on every part of the trees and bushes when they are dry. Passing black thread in all directions over the bushes sends sparrows elsewhere, and it can be done ten or twenty times more quickly with a simple appliance, known as Royle's Garden Webber, than by passing the thread through the fingers. Neither this nor any applications can save the buds of Black Currants if they are infested with the mite.

A Stubborn Pear Tree (Kewhurst).—We are obliged by the reference. The tree, large in proportion to its roots when removed, has by no means recovered from the severe check it received. Some trees of the same nature are years before they make healthy growth, while others, especially if not assisted, never make good progress, but remain mere stunted cripples. Assuming your tree is covered with blossom, do not hesitate to remove three-fourths of the trusses or more. Perhaps the best plan would be to remove them all, though you may not like to act so thoroughly. This you may remember, however, that the fewer the number of trusses retained the greater the chance of leaf or wood growths issuing. Possibly the branches were not cut back sufficiently to clean healthy looking wood. Wherever there are signs of wood growth there should be no blossom beyond it. It might be well to cut some of the branches out entirely. This depends on the number, but if the more promising are 15 to 18 inches apart there will be quite sufficient for bearing fruit. Should several of the blossoms set, as those of enfeebled trees often do, the fewer the fruits that are allowed to swell the better. When a plant or tree is enfeebled, yet has sufficient strength to produce flowers, it will produce them in an effort to perpetuate its kind by the production of seed, even if it perish in the attempt. Give another dressing of nitrate of soda, scattering it evenly on the soil, at the rate of $1\frac{1}{2}$ oz. to the square yard from the stem outwards beyond the extension of the roots. Run the hoe through the surface frequently, when it is dry, to admit warmth, and before hot weather sets in give a pailful or two of warm water and cover with manure to prevent evaporation and the consequent shrinkage and cracking of the soil. Syringe the tree as often as you like, or can, in dry weather. If the soil is moderately dry now a pailful or two of decidedly warm water, with 1 oz. of nitrate of soda dissolved in each 3 gallons, might stimulate root action more quickly than by sprinkling the salt-like fertiliser on the surface. Your immediate primary object should be to incite free root action and wood growth, regarding blossom and fruit at present as of secondary importance. Large trees with few roots are tempting to the inexperienced, but all the same delusive, and often dear at any price or none.

Names of Moths (Somerset).—The author of the series now appearing in our columns on the garden species requests us to state that he follows the nomenclature adopted by Doubleday, and supported by Newman, which in some respects differs from that of Westwood and Morris, which you mention. There is also a still newer and third nomenclature, based on a revision of names and positions, which has not yet received general approval. We should recommend you to get a synonymic list of British Lepidoptera, which was compiled for the entomologist, and is published by Simpkin, Marshall & Co. for 1s. This will enable you to refer to any species under its different names.

Black Hamburg Leaves with Scarlet Leaf-ribs (R. D.).—We have not seen leaves similar to those submitted before, but on subjecting them to chemical tests there appeared a considerable percentage of potash, and this probably may be the cause of the high colour—very beautiful under artificial light—of the main and side ribs. We do not consider you could do anything but supply a dressing of superphosphate (30 per cent. soluble phosphate), using 2 ozs. per square yard, or preferably apply that quantity in 4 gallons of water. There is no disease, and we should consider, with the superphosphate, the Vines would finish their crops well. Have you used any particular or special fertiliser? The leaves are very fine; yet we advise more air, especially in the early part of the day, so as to dissipate any moisture before the sun acts powerfully upon the foliage.

Coating Boxes with Creosote and Tar (Inquirer).—The fumes of creosote and also of gas tar are very injurious to vegetation, and if these are the articles employed on the boxes we do not consider they would be suitable even for such strong rooted plants as Tomatoes, whilst the fumes given off would injure their somewhat tender foliage. We have found such to be the case, and on the other hand, cutting boxes treated with creosote, and stood aside for a time till the volatile parts or fumes were parted with, answered their purpose satisfactorily. Likewise, boxes treated with Stockholm tar and sufficient creosote to thin it for readily applying with a brush have proved innocuous to plants placed in them, the smell being allowed to pass off before using the boxes. We use, however, a mixture of linseed oil and Stockholm tar for oak tubs, and of Stockholm tar and paraffin oil for deal boxes, and find no evil results. The oils are used to the extent of rendering the Stockholm tar workable with a brush in a similar manner to other paints.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (W. T. C.).—1, A seedling from Blenheim Pippin; 2, Winter Majetin. (B. E. W.).—1, Wellington; 2, Bramley's Seedling; 3, unrecognisable from specimen sent, possibly a local variety.

Names of Plants.—We only undertake to name species of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. L. S.).—*Choisya ternata.* (E. F. J.).—1, Berberis aristata; 2, Retinospora plumosa; 3, Berberis Darwini. (B. W.).—*Lycaste Harrisonæ.* (G. D.).—1, Asplenium bulbiferum; 2, Adiantum pedatum; 3, Selaginella Kraussiana. (C. E. C.).—1, Rhododendron Gibsoni; 2, R. hirsutum. (A. A.).—1, Dendrobium Wardianum; 2, Odontoglossum crispum; 3, Dendrobium fimbriatum; 4, Odontoglossum Pescatorei. (M. B.).—*Rubus spectabilis.* (J. C.).—Rhododendrons are florists' flowers which can only be named by comparison in a large collection. (H. G. T.).—A moderately good light form of *Lælia purpurata*. It is not a trouble but a pleasure to assist our subscribers.

A FORTUNE FOR SOMEONE.

It has been said, and with perfect truth, that larger fortunes have been realised by what appeared trivialities than by great undertakings. Some little implement or tool, or some improvement on an existing implement—a thing used by the million, catches on, and the inventor's fortune is made. Sometimes, of course, the invention or improvement is the work of years of patient toil; sometimes, again, it is the happy inspiration of the moment. We do not know who first introduced tinned food, but a trade has now sprung up. Everything lends itself to the process—fish, flesh, vegetables and fruit—and it is marvellous how excellent are the results. Milk, too, is prepared and preserved, and thus keeps good for an indefinite period. We always think milk must have presented many difficulties, but these seem to have been successfully overcome, and the most delicate babies are reared, not direct from the cow, but direct from the tin of condensed milk—indeed we have found it assimilated when other kinds could not be retained on the stomach.

So far, so good; but with all our ingenuity we are still wanting in one thing—we have not yet found out a really good method of

treating the homely egg. We depend on the daily supply. Like the manna of old, it has to be sufficient unto the day; but, alas! our hens do not look at the matter in that light, and often fail us in our greatest need. When the garden is full of ripe luscious fruit we do not feel so much the need of a good egg supply; rather do we look for them when the summer is over and past and our daily meals are a trifle monotonous. At present all good things come at once—fruit, vegetables, young meat (lamb, veal and chickens), and eggs by the hundred.

We just glance down the list of Saturday markets (in north and mid-England) and see the prices ranging from sixteen to nineteen eggs for 1s., cheap food for the million; but, alas! for the poor producer, how he gnashes his teeth and looks from side to side for a more remunerative market. Why should all these eggs, so good and really valuable, be hurled on to the market at once?

And then come the days of famine, or rather weeks, when eggs get to eight for 1s. We want some readjustment somewhere, but up to now no adequate means for preservation has been discovered. We think there must be some way out of the difficulty, for surely eggs are not so difficult to deal with as milk. They do not take a taint so easily; they are so effectually protected that they cannot be made the vehicle for the spread of disease, and yet so far they baffle the chemist and the inventor.

Of course, as no preserved milk can equal in flavour and bouquet the warm, rich fluid freshly drawn, so neither do we expect preserved eggs to equal the newly laid; and yet to how many varied and excellent uses could these eggs be put where their age would be no bar to their use! Every good housewife has tried her hand at this attempt to meet, as it were, the months of famine, and innumerable are the recipes passed down from mother to daughter.

Of course, a careful woman will, in most instances, be assured of a measure of success; but, alas! we want some method that will do for the million whose zeal is perhaps greater than their judgment, and that method has yet to be found. The egg is a delicate and valuable food enclosed in a shell more or less porous. The action of the air on the edible portion soon causes serious deterioration, and therefore something must be provided which effectually excludes the air. Say eggs are put away now not to be used till October or November, that means preservation for six months.

The Germans have been trying a series of experiments, and the results obtained are very instructive. The eggs were put away for eight months, and then brought out and tested with the following results:—

- I.—Eggs preserved in salt water all uneatable, salt having penetrated the shell.
- II.—Wrapped in paper, 80 per cent. bad.
- III.—In a solution of salicylic acid and glycerine, 80 per cent. bad.
- IV.—Rubbed with salt, 70 per cent. bad.
- V.—Preserved in bran, 70 per cent. bad.
- VI.—Covered with paraffin, 70 per cent. bad.
- VII.—Varnished with a solution of glycerine and salicylic acid, 70 per cent. bad.
- VIII.—Put in boiling water fifteen seconds, 50 per cent. bad.
- IX.—In a solution of salicylic acid, 50 per cent. bad.
- X.—Varnished with waterglass, 40 per cent. bad.
- XI.—Treated with a solution of alum, 50 per cent. bad.
- XII.—Varnished with collodion, 40 per cent. bad.
- XIII.—Covered with lac, 40 per cent. bad.
- XIV.—Varnished with sward, 20 per cent. bad.
- XV.—Preserved in ashes of wood, 20 per cent. bad.
- XVI.—Treated with boric acid and waterglass, 20 per cent. bad.
- XVII.—Treated with manganate of potassa, 20 per cent. bad.
- XVIII.—Varnished with vaseline, all good.
- XIX.—Preserved in lime water, all good.
- XX.—Preserved in a solution of waterglass, all good.

The three last tests came out well, but even these leave a good deal to be desired. Varnishing with vaseline is too tedious a process, it means so much handling, and the difficulty will present itself to any thinking mind how to insure that every atom of the shell be covered. As one leak will sink a ship, so one pore unstopped admits air, and all the work is undone.

Well, as to lime water, our own experience makes us doubtful on the matter. Sometimes they come out all right and good (the white

is always a little watery), and at other times the yolk is set perfectly hard and ball-like. No lime-preserved egg is ever fit to boil, and often where the most care has been taken there is always a more or less strong flavour of lime—most undesirable in so delicate a food.

Whether waterglass will ever become a popular mode of preservation remains to be proved. It is a substance of which the majority of us know little. Waterglass is an alkaline silicate, which dissolves in water. In appearance it is like a thick sugar syrup. It can be bought at 10s. or 12s. per cwt., and is used in proportion of one to ten. The water should be previously boiled, and mixed with the waterglass when cold; the mixture should then be poured over the eggs, which are packed in a vessel, till the topmost ones are perfectly covered.

It is absolutely necessary to see that the eggs so preserved are perfectly fresh, and free from the slightest soil or stain.

WORK ON THE HOME FARM.

We are rejoicing now in typical April weather, shower following shower at exceedingly short intervals; the rain is doing wonders to all kinds of vegetation, and we are regretting that the nitrate of soda which should have been benefiting the Wheat is still unapplied through delay in delivery.

The rain is driving the horses off the land as regards harrowing and cleaning operations, so we must turn to the yards which are very full of manure and get out what will be required for the Swedes. The Mangold land is ready for ridging, and if ridged up the first fine day will then be ready for its share of the muck. Too much of it can hardly be applied for Mangold if the weather be moist and the manure solid, and it must be good for Mangold to do well; light strawy manure only helps the land to dry out during a drought, and does little good to the crop.

We have lightly rolled the Potato ridges, and shall ridge them up again with a one-horse earthing plough. This will do much to preserve a good tilth, and will tend towards economy when weeding time comes.

The mention of weeding reminds us that Wheat is growing fast, and where any hoeing is required it had be better done at once; where Wheat is thick and strong with little twitch in it a good harrowing will answer all the purposes of hoeing, but where Wheat is foul with twitch or thistles the hoe must be used, and, after this date, the earlier the better. So far, we hope this is not going to be a thistle year, as there are very few showing their heads above ground as yet.

We referred above to the manure used for the Swede crop. We do not intend to infer that manure is necessary for Swedes; in fact, when the heavy cost of carting and spreading farmyard manure at the busiest time of the year is fully taken into account, we are convinced that unless the land is clean enough to manure during the winter it is most economical to use the farmyard muck either in July upon seeds for Wheat or upon any land suitable for Oats or Potatoes, as for the latter crops the carting and spreading could be done during the winter season.

Some farmers, perhaps, may say that if we are always trying to do all the work in winter when the days are short, the result may be not what we are aiming at, but we have never found too much spare time on our hands at midsummer, and if all the work be done, what more suitable time is there for the farmer to take a holiday, and who shall say that he does not deserve one?

REMARKS.

- 10th.—Overcast morning with spots of rain; wet from 1.30 to 2.30 P.M.; bright sunshine after 3.30 P.M.
 - 11th.—Overcast morning; sunny at times in afternoon; slight showers in evening.
 - 12th.—Rainy till 9 A.M.; overcast morning; generally sunny after noon; fine night.
 - 13th.—Alternate cloud and sunshine throughout.
 - 14th.—Generally overcast, with frequent spots of rain, but an occasional gleam of sun; showers at night.
 - 15th.—Showery till 4 A.M.; sunny from 9.30 A.M., and brilliant afternoon.
 - 16th.—Brilliant early; cloudy at times in the day.
- Temperature slightly above the average, but a very normal week for the season.—G. J. SYMONS.

DOBBIE & CO.'S

ANNOUNCEMENTS.

DAHLIA PLANTS.

WE ARE NOW BUSY SENDING THESE out to all parts of Britain, and to many continental countries. Those who have not already ordered, and who are desirous of having Dahlias early in bloom, should send in their orders at once. When received (in Neponset paper flower-pots if desired with balls of soil whole), they should be potted into 4-inch pots in nice, rich, open compost, and grown on for two or three weeks in a warm house or frame, afterwards gradually hardened off, and planted out 1st June. This is the way to obtain plants which will begin blooming in July.

We grow the best, and only the best, varieties in all the different sections—

Show and Fancy, True Cactus, Decorative, Pompon, Single, and Single Cactus,

and offer our Selection at the uniform price of

5/- per dozen (in Neponset pots, 5/6), Carriage Paid.

35/- per 100 (in Neponset pots, 38/-), Carriage Paid.

(In not less than 50 varieties).

SPECIAL OFFER of the FOLLOWING SPLENDID NEW CACTUS VARIETIES of 1897.

BRIDESMAID, CEDRIC, CINDERELLA, CYCLE, FANTASY, STARFISH, FLOSSIE, ENSIGN, JESSIE, H. STREDWICK, IONA, MRS. KINGSLEY FOSTER.

The 12 for 15/6, post free. Any 6 for 8/6, post free. In Neponset pots. Single plants, 1/6 each; post free, 1/9.

Buyers wishing to make their own Selections can have Catalogues on application.

THE DAHLIA: Its History and Cultivation. A HANDBOOK FOR ALL GROWERS.

The *Leeds Mercury* says:—"With the aid of this pretty illustrated volume the cultivation of this superb flower should present no difficulties to anyone."

Price, in stiff paper covers, 1/-; in cloth boards, 1/6; post free.

FUCHSIAS.

The Finest Named Single and Double Varieties. Good Plants from single pots.

6 SINGLE AND 6 DOUBLE 3/6 post free.
3 " 3 " 2/- "

PELARGONIUMS.

Fine Plants. Splendid Value.

12 GRAND SINGLE VARIETIES, post free for 4/6, 6 for 2/6.
12 GRAND DOUBLE VARIETIES, post free for 4/6, 6 for 2/6.
12 SPLENDID REGAL AND SHOW VARIETIES, post free for 6/6, 6 for 3/6.
12 SCENTED GERANIUMS, lovely cut foliage and delicious perfume, post free for 4/6, 6 for 2/6.

Cuttings of all the above Half-price.

VIOLAS.

"Messrs. Dobbie & Co. stand first in Viola culture."—*Birmingham Daily Gazette.*

FOR EXHIBITION OR FOR CUT FLOWERS.—We offer one dozen of the Very Finest Violas, our selection, including several recently introduced varieties, for 2/6, post free.

50 in 25 of the very Finest Varieties, 10/-, carriage paid.

100 in 50 of the very Finest Varieties, 20/- carriage paid.

This last lot will put any one at once into the possession of a really superior and complete collection of Violas.

FOR BEDDING.—100 in 12 varieties for 12/6, carriage paid.

DOBBIE'S

FERTILIZING COMPOUND

A High-class Artificial Manure for all Horticultural Purposes.

SAMPLE TIN BOX, POST FREE, SIXPENCE.

DOBBIE & CO.,

ROYAL FLORISTS, ROTHESAY.

No. 931.—VOL. XXXVI., THIRD SERIES.

CARTERS' HOLBORN PRIMULA.—Our Prize Strain of the beautiful winter-flowering conservatory plant is the finest in cultivation. We were the originators of the blue variety now so popular. Fresh seeds, in all colours, mixed, including white, scarlet, blue, and pink. In Sealed Packets, price 2/6, 3/6, and 5/- each, post free.

CARTERS' BRILLIANT CINERARIA.—The very finest strain ever submitted to public notice. Awarded Highest Prize, Medal Royal Botanic Society, 1897, Royal Horticultural Society, 1898. A customer recently sent us blooms measuring 3½ inches across. Fresh seeds, all colours, mixed. In Sealed Packets, price 2/6, 3/6, and 5/- each, post free.

CARTERS' VICTORIA CALCEOLARIA.—Our grand strain is the very perfection of scientific culture, being compact in habit, and brilliant in colour and size of blossoms. A customer writes: "The plants were a perfect picture, many with 600 blooms; we took first prize." Fresh seeds, all colours, mixed. In Sealed Packets, price 2/6, 3/6, and 5/- each, post free.

CARTERS' INVINCIBLE GLOXINIA.—We have brought this fine summer decorative plant to the highest excellence. H.R.H. the Princess of Wales greatly admired our exhibit at the Temple Exhibition last summer, and was graciously pleased to pronounce it an "exquisite display." Fresh seeds, all colours, mixed. In Sealed Packets, price 2/6 and 5/- each, post free.

CARTERS' THE QUEEN'S SEEDSMEN, 237, 238, and 97, HIGH HOLBORN, LONDON.

FOR SALE.—A SURPLUS STOCK OF YOUNG CROTONS and STOVE PLANTS, and a few ORCHIDS and ECHEVERIAS. Particulars on application.—J. MOODY, The Gardens, Sutton House, Sutton-on-Hull.

CACTUS DAHLIAS.—Annie Jones, Fusilier, J. E. Frewer, Mrs. W. Noble, Mrs. L. Seymour, Lady Penzance, Matchless, Gloriosa, Mrs. Borne, and three others for 4/-. List free.
W. BAXTER, The Nurseries, WOKING.

CLEARANCE SALE.—100,000 BEGONIA TUBERS, large erect flowering. Singles, 12, 2/-; 25, 3/6; 50, 6/-; 100, 11/-. Doubles, same price. Smaller, 12, 1/6; 25, 2/6; 100, 8/-, for cash.—JOHN WELLS, Begonia Nursery, Ryarsh, Malling, Kent.

DEFY THE BIRDS by Buying our Noted ROTLESS TANNED NETTING, as supplied to the Principal Gardeners in the Kingdom. Orders over 5/- value are sent Carriage Paid. 100 yds. by 1 yd., 3/-; 200 yds. by 1 yd., 6/-; 300 yds. by 1 yd., 9/-. Can supply any length and width.—UNIVERSAL SUPPLY ASSOCIATION, East Street Works, Reading. (Name Paper.)

HEATING APPARATUS.—Medals 1875 and 1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2/6; post free, 2/10.—JONES and ATTWOOD, Stourbridge.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—HIRST, BROOKE & HIRST, Ltd., Leeds.

ALL WHO WISH GRAND RESULTS should use THOMSON'S IMPROVED VINE, PLANT and VEGETABLE MANURE. This Valuable Manure is yearly growing in public favour. Can be had of all Nursery and Seedsmen, or direct from the makers, WM. THOMSON and SONS, Ltd., Tweed Vineyard, Clovenfords, Galashiels, N.B. Price Lists and Testimonials on Application. 1 cwt. and upwards Carriage Paid to all stations in Britain and Ireland. London Agent—Mr. J. GEORGE, 14, Redgrave Road, Putney. Agent for Channel Islands—Mr. J. H. PARSONS, Market Place, Guernsey. Also THOMSON'S SPECIAL CHRYSANTHEMUM MANURE. ½ cwt. Carriage Paid to all stations in Britain and Ireland.

HARDY BORDER PLANTS OF THE BEST TYPES ONLY.

Many Herbaceous Plants are grown from seed, but it is not generally known that although some come true in this way, many others vary greatly in habit, shade of colour, or freedom of bloom. To secure the best display it is wiser to pay a little more for stock propagated from the best types by cuttings or division, than to buy at a little lower price stock raised at random from seed. At the Oldfield Nurseries, the Herbaceous Plants number some hundreds of thousands, and all through the season the department is worth inspection by all lovers of this class of plants. A CATALOGUE, giving a large mass of useful information on them, may be had Post Free.

CLIBRANS,
ALTRINCHAM AND MANCHESTER.

Journal of Horticulture.

THURSDAY, APRIL 28, 1898.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St. London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

FRUIT BLOSSOM.

IF the hardy fruit crop in the summer and autumn could be measured by the blossom of trees and bushes now, the yield would be prodigious. But there can be no such reliance. An extraordinary profusion of blossom is not by any means synonymous with a corresponding abundance of fruit. If it were thousands of trees would be borne down with their load, and this of little value because of the clustered branches, and consequently trashy products, while the resources of the soil would be wasted and the trees enfeebled by the strain of their crushing burden. Overwhelming crops, however, need not be anticipated. They may follow, or they may not. No one knows; but one thing is certain—if one tenth of the blossoms with which trees innumerable are now densely covered were to set, and the fruit allowed to swell, the crops would not possess half the value that the yield would if the fruits were half the number, and consequently twice the size. Cold winds, frosty nights, and dry soil are not favourable to the setting and swelling of fruits.

The extensive fruit plantations in the Thames Valley and elsewhere are now veritable pictures of chaste beauty. Plums and Cherries are simply heaped with myriads of silvery blossoms, and Pears are like mountains of snow. Apples, as a rule, seem equally laden, or overlaid. This applies to young trees and to old that are in bearing condition. Many free growing trees are not allowed to be productive because of the senseless way in which the branches are cut back each year, resulting in a forest of crowded growths—to be cut back again. That is the way in which stupid people make and manage "pyramids," and not a few of these people, it is painful to say, pass through the world as gardeners. Their work of mutilation and fruit prevention is apparent here and there all over the country. A few of these tree trimmers, it is satisfactory to observe, are learning better. They are beginning to shorten the roots of exuberant trees to arrest growth, and thin out the branches to promote fruitfulness, instead of hacking them back yearly; but unfortunately some men are too wise in their own ignorance to be taught the better

methods that are practised by genuine gardeners and skilled cultivators with the best possible results.

It is not difficult by intelligent methods to train trees into habits of fruitfulness without impairing their health; but neither is it difficult to cover young trees with blossom before they are capable of bearing many clusters of fruit without constitutional—in many cases permanent—enfeeblement. There are at this moment thousands of young fruit trees in various parts of the country which have been planted one or two years, and their few long young branches either not shortened at all, or insufficiently, which are now wreathed with clusters of blossom, expanded, or approaching that stage. Almost every bud seems to have changed from a small leaf or wood bud into a blossom bud, including that at the end of each branch. If these blossoms are allowed to set fruit that will be the best possible way of making the trees, not free growers and increasingly healthy bearers, but practically useless chronic cripples.

All such precocious pigmies should be relieved of most or all their blossom trusses at once, and it is especially important to remove all terminal clusters, cutting the tips off the branches back to the most promising small wood bud that can be found, and failing its discovery to the cleanest and healthiest looking portion of the stem, for, if possible, forcing latent buds into activity. The primary object with such trees should be to obtain free growth, not bouquets of blossom. It is very easy by-and-by, as the trees gain strength, to turn them into valuable fruit producers.

Not only are many recently planted trees in the open, which were intended to develop into serviceable bushes or standards, in danger of being stunted, perhaps beyond recovery, by the transformation of growth buds into blossom buds, but there are also a large number of cordon trees intended to cover lofty walls, that will not reach the top for years, if ever they do, unless relieved of the blossom buds, which form a cluster at the apex. When such trees are permitted to terminate in a bunch of spurs, as many are, it is no easy matter to make them produce free extension growth. Every young cordon tree that is crowned with a cluster of blossom should have that cluster removed at once, with others immediately below it. The same remark applies to the side branches of espalier trees, as well as to trees that are intended to have their branches trained horizontally to walls, or the chance of their free extension will be extremely remote. We know of trees, not a few, of all the forms named that will never cover the wall space hoped for, or meet each other in lines of espaliers, if not assisted in some such way as suggested, and many of them must be cut very severely back indeed before anything like satisfactory growth can be expected. As a matter of fact they ought to have been cut back long ago, or perhaps better still, burnt. True, they cost little. They were called "cheap" trees, but actually worth nothing. They were worse than no trees at all, as occupying and wasting space that might have been utilised with healthy, thrifty trees, combining free growth with fruitfulness.

We last week gave advice to a correspondent (page 358) on the management of a "stubborn Pear tree." It was a large tree when moved, and though it blossomed freely, it neither produced fruit nor made any growth. We do not know whether the tree was purchased, or removed from one part of the garden to another; nor does it matter. We suspected its state, and advised accordingly. Sample branches have now been received, and they are even worse than anticipated. They are indurated, attenuated, more or less contorted, with not a growth bud to be seen, every one of such buds having changed into blossom buds, and these so weak that not one flower in a thousand has sufficient vitality to set a Pear. Such trees as this, and there are numbers of them in the country struggling between life and death, can only be saved, if then, and made useful by removing entirely the weaker of the stunted branches, and cutting the more promising boldly back to more than two-thirds their length to the cleanest and most healthy parts, as if preparing for grafting. Then by concentrating the root force, such as it is, on the shortened parts and syringing frequently in dry weather, latent buds may push, and the closer the pruning the more likely will they be to do

so, and produce healthy growths. We experimented with some trees in the direction indicated four years ago. They are now as healthy as could be desired, having made excellent growth, whereas if they had been left alone they would certainly have died.

Some people are so fond of a bargain that they rejoice in the possession of big, stunted, nursery stagers full of blossom buds, for half a crown each, whereas they would have to give 2s. for trees not half the size, and with not a tenth in number of blossom buds on the clean young branches. Such purchasers are satisfied they have got the best of the vendor in the transaction, but nothing is more certain than that the vendor has got the best of them in getting the large-topped and few-rooted moribunds off his hands. It is pleasant to see a good display of bold blossom on healthy trees, but pitiable to observe so many trees in a comparatively infantile state so cruelly overlaid, that they can, if left unaided, be little better than stunted starvelings the remainder of their days.

We have lately had the pleasure of visiting two fruit gardens—one of them mainly experimental, the other commercial. The former is Chiswick, where the same varieties of Apples on different stocks are, with trivial exceptions, all growing and blossoming alike. There are dozens of young Apple trees, and not a man in England capable of determining which kinds of stocks half of them are on. Their healthy branches are all alike wreathed with blossom. The fine pyramid Pears, as well as cordons on walls, are crowded with blossom. Plums and Cherries on walls are white as sheets; but a valuable collection of young Plums, planted by Mr. Barron and grown as bushes, have been denuded of nine-tenths of their blossom buds by what sentimentalists describe as that "friend of the gardener," the sparrow. With favourable weather Chiswick will be full of fruit, except Peaches. The terrible blizzard on Boat Race Day settled the blossom on wall trees as completely as Oxford settled Cambridge; while the prolonged continuance of a dense fog, when the trees under glass were in bloom, brought down the blossoms. One late-flowering tree was not in bloom during the reign of the fog fiend, and the blossoms of this tree are setting freely.

The other fruit "garden" visited was that of Mr. Edwin Ellis in Surrey. It comprises about 80 acres, and as viewed during blossoming time from a commanding point on the high saddle-like ridge that runs through it, and looking down the deep valleys on either hand, the four sharply sloping sides occupied by standard Plum and Apple trees rising above an undergrowth of bush fruit—chiefly Gooseberries—the scene was such as could not in its way be seen elsewhere. It was an undulating cloud of silvery blossom in a setting of tender green. A plantation of young Pears on the ridge presented a mass of blossom—by far too much, and if a tithe of it sets there will have to be a severe thinning of fruit. The soil is of a sandy nature, and rain with cloudy nights urgently desired.

The effect of root-pruning in arresting the extension of growth buds, and thus transforming them into blossom buds, is strikingly apparent in a new plantation of a few acres of young Apple trees, the trees having been thinned out of the larger area. They had been cut back twice or thrice after planting, for increasing the requisite number of branches, and these allowed to extend. The necessary shortening of the roots in the removal of the trees caused the buds to change, and each branch is now clothed with blossom from base to summit. There has been no summer pinching or any such manipulative process, and none was, or is, needed for making healthy Apple trees fruitful. It is a case of the thin disposal of the branches in summer, so that the sun can shine between them, and arresting the roots if growth becomes exuberant. It is easy to change small, pointed leaf or wood buds into bold, oval-shaped blossom buds; a far more difficult, if not impossible task, to effect a change the other way about, and make stunted trees, which produce nothing but blossom, and the attendant whorls of leaves, healthy growers and prolonged bearers of first-class fruit.

A welcome change in the weather occurred on Tuesday, and if milder weather follow the refreshing rain that was so greatly needed, fruit prospects will be materially improved.

LAWNS AND ALLIED SUBJECTS.

(Concluded from page 327.)

CROQUET GROUNDS AND BOWLING GREENS.

THE revival of croquet some three years since leads one to infer that this game will win its way to a measure of that favour accorded to it thirty years ago. Unlike lawn tennis, it does not necessitate a specially prepared space in the form of a parallelogram for its exclusive requirements, although all that is essential in the matter of a thoroughly even, well-kept sward for tennis playing, is equally applicable to the space upon which the croquet hoops are to be pitched. Within the kept grounds surrounding an English home, and in the more immediate vicinity of it, one or more portions of the lawn embracing those features of comparative privacy and pleasing surroundings can be at a minimum of expense adapted to the purpose; but, needless to say, such will be upon those parts of the lawn where little deviation from the level, natural or artificial, obtains. The extent of the portions devoted to this will, as a rule, be not less than 60 feet by 50 feet, and may, according to circumstances, considerably exceed that. Given a good level plateau with scrupulous attention paid to its keeping, particularly in the way of a good grass-collecting machine being used, little remains to be said beyond that an occasional vigorous use of the birchbroom may be given with advantage; the object being that the balls should run clean in damp weather.

The bowling green in the form of a sunk panel is now rarely to be met with, yet serving, as it can be readily made to do, the dual purpose of that which its name implies and a skating rink on a small scale, one wonders that it is not more in evidence. Owing to the bowling green being seldom requisitioned for its legitimate purpose, excavating to the orthodox depth of 30 inches may in most cases be considered unnecessary, half of that depth being probably sufficient. If this is made either in the form of a parallelogram or an oval embracing an area sufficiently large for croquet playing, and for which purpose it is eminently adapted, given the congenial surroundings of groups of Rhododendrons or other ornamental plants of a similar nature, it forms a pleasing and characteristic feature in the *entourage* of the kept grounds. With due provision for the inlet and outlet of water during winter, when the shallow reservoir formed by the sunk panel is converted by a few degrees of more or less continuous frost into a safe medium for the enjoyment of skating, the so-called bowling green commends itself, I think, for consideration to those who would, in every sense, make the most of their pleasure grounds. Granted that the water supply from a higher level is at hand, the small amount of engineering necessary to convey it to and from the bowling green, with the provision of plugs obviously necessary, presents in most cases little difficulty. Outlets at the sides must be provided to carry off surface water, and in excavating into what may be an uncongenial subsoil, the remarks previously made upon its unsuitability to the growth and maintenance of health of the finer grasses, are especially applicable.

Grass steps partake, perhaps, more of the ornamental than useful in character, and may wisely be regarded from this point of view, for where continued use renders them unsightly something more substantial may well be employed. Yet if more space were afforded in constructing them than is often given much of this might be obviated. Some little difficulty is often experienced in their formation. In the worst case I had to deal with the best results were obtained by building up the steps with ordinary turves packed face downwards strata upon strata to the required depth, the whole being well watered and beaten as the work proceeded, the rising part of each step being cut with a sharp verge-cutter to a slight angle inclined inwards. After being thus consolidated and properly shaped a sprinkling of rich compost was given, and sheets of turf as large as it was possible to handle formed the cover to the whole, being gently but firmly beaten into position. A broad flight of steps thus formed were as solid and satisfactory after ten years use as at their creation, although it must be added that workmen were, as a rule, prohibited from using them.

MOWING.

Modern methods of mowing lead one who can look back prior to the lawn mower coming into general use to conclude that we have gained a great deal, but lost something. Young gardeners, to whom the scythe is an antique implement, can scarcely credit the possibilities which lay in it when wielded by skilful hands, and practically they have no opportunity of comparing the new order of things in this respect with the old. I, at least, from my own experience now regard scythe mowing as a lost art, and regret that it is so. Taking a broad view of scythe *v.* machine mowing, the best methods appear to be those where the scythe is brought in as an auxiliary to the machine. For instance, the first mowing of the season, which may well be delayed until a fairly good growth of grass has taken place, should be done with the scythe, and a thorough sweeping and rolling given to

the sward. Such measures are not only invigorative to the grasses, but cleanse and pave the way for good machine work to follow. Wherever I have been located, and whenever it was possible during the family's absence to allow old lawns to grow freely until it was necessary to resort to the scythe to make them again amenable to the machine, it was done, and proved decidedly beneficial. However, as previously inferred, the garden labourer of to-day, as a rule, chops and hacks and scores in every direction but that of success in the endeavour to practise what he has never learned, and what few gardeners are now qualified to teach.

If it is admitted that few can now perform creditably with the scythe, the conclusion is generally arrived at that most garden workmen can use a machine. In a sense only is the latter true, for the intelligent workman who, understanding the anatomy of his machine, works in sympathy, if it may be so termed, with it, can alone do justice to its mechanical capabilities. As there are workmen and workmen, so are there machines and machines, all good in their way, but variously adapted to the purpose. In conjunction with this phase of our subject may be taken the various methods of machine mowing. On the larger scale, and with a large extent of comparatively level surface, the horse-power machine is, of course, *facile princeps* in its working, but with undulating and obstructed ground (by planting in any shape or form) the insistence of its use as a saving of labour is, I believe, a mistake, and often detrimental to good effect. The good work done by 16-inch hand machines, and the ease with which the lighter makes of them can be propelled, leaves little to be desired or attained in that direction. After the preliminary clearing of the sward by scythe mowing and sweeping, I see no reason why what is known as the American method—viz., allowing the machine to scatter the grass instead of collecting it—should not be resorted to; that is, when the mowing is done with uninterrupted regularity, weekly, or even bi-weekly, when the grass is in the full flush of growth.

On the choice of machines there is less to say than on the use and abuse of them. Cheap machines there are, of course, answering perfectly for the limited requirements of villa residences, which are ill adapted to the continual strain imposed by almost constant working. My experience tends to the preference of a machine with high driving wheels, and this will be found almost a necessity in the case of mossy lawns of a yielding nature. A good workman will make himself acquainted with all parts of his machine, and take the opportunity afforded by a wet day to thoroughly clean and overhaul it, readjusting to that nicety essential to its satisfactory working. In selecting a machine it should not be overlooked that its life can be prolonged by being able to renew the worn parts when necessary; hence a proper understanding with the vendors, that such can be obtained when required, will prevent a disappointment not infrequently met with when fashions change, and each season sees new patterns on the market, although the improvement may be questionable. Whilst advocating "the American method" of distributing instead of collecting the cut grass, the grass-box must be considered as indispensable in the mowing of the tennis and croquet grounds, and where possible, it may be also worth repeating, that a daily run over with a machine specially kept for the purpose is indubitably the best economy.

It is still an open question as to the matter of oiling the cogs of the driving wheels, one experienced workman I am acquainted with never doing so, and applying very little to the bearings. As a rule, far too much oil is applied to the lawn-mower, and the end of easy running is defeated by an accumulation of grease and dirt. My humble friend alluded to above has, by a little attention to details and intelligent practice, reduced his mechanical mowing to a fine art, and there are few, if any, better examples to be seen of the lawn as it should be, a well kept lawn, that grand feature of English gardens.—SYLVA.

HARMFUL AND HARMLESS GARDEN MOTHS—19.

THOSE birds which largely supply their young brood with insects, especially grubs and caterpillars, thereby meriting our gratitude (which they do not always get), may be observed very busy amongst trees and shrubs, also in low herbage or grass. Probably they pick up their prey more rapidly on the trees, but from low plants they obtain some of the juiciest caterpillars. There is frequently a migration amongst insects after winter. Caterpillars living near the ground in autumn seek food upon twigs and branches in spring, and many that have begun existence high up, attain their maturity by feasting upon the herbage of the new season.

Amongst the Noctuas this is often the habit, and their fat caterpillars are lucky if they escape birds and gardeners, beside insect foes, to hide while in chrysalis beneath the soil; even then they may be dug up to be devoured. Gardens sometimes produce specimens of the double dart, or *Noctua augur*, in its various stages. The greyish

brown moth flies in June, and the young caterpillar feeds a little while later, then hibernates till April. It is taken just now on Hawthorn hedges and plants growing near them, a very smooth caterpillar of purplish brown, with two narrow waved stripes, and some small white spots, but it is not abundant enough to be mischievous. Akin to this is the caterpillar of the moth called the double spotted square spot (*N. triangulum*), which feeds during April and May. In the autumn it eats the leaves of Bramble or Sallow; the spring food is varied. It is partial to Primroses and allied species, occasionally it helps to clear off common weeds, such as Chickweed and the Lamiums. The moth is rather handsome, having well-defined markings in shades of brown and buff. Sweets attract it about midsummer, and it is reported from all parts of Britain.

Sallows and Willows of several kinds are not unusually planted in or near gardens, and they supply food to several stout-bodied species akin to the two named above, their caterpillars consuming the foliage, but, should they fall off, they sometimes change their diet. We may take from some Sallow at the end of April the caterpillar of the purple clay (*Noctua brunnea*), which rolls into a compact ring when touched; it is velvety, brown, marked with black and white. The moth is also brown, delicately marbled and banded, having two conspicuous white spots. A much lighter moth, very variable in colour and pattern of wings, is oddly called the ingrailed clay, or *N. festiva*—the Latin name has perhaps an allusion to its appearance at the height of the summer season, when Nature displays her full beauty. April and May are the caterpillar's season; it hides amongst the twigs of Sallow, though is doubtless discovered by birds. It resembles the preceding, but is somewhat darker, having a few pale spots and pale feet. Much smaller, and quite of a different aspect, is the flame shoulder moth, *N. plecta*, so styled from a conspicuous whitish-yellow dash of colour along the edge of the brown upper wings; there is another dash near their base; the under wings are white. Woodruffs and other low plants supply food to the caterpillar, which is of dingy hue and slim-bodied, not easily perceivable when it is crawling or resting on the soil; it feeds during July, and is not uncommon.

The Hebrew character (*Tæniocampa gothica*) is a moth of spring, one that many gardeners have seen reposing by day on trees or walls at a time when such insects are abroad only in small numbers. One peculiarity is the mark on the purplish brown wings that suggested the English name; another is the length of the scales, which make the moth look woolly. Numerous garden shrubs furnish food to the caterpillar, which is full grown in June. Its strength of jaw is proved by its power to masticate tough leaves, such as those of some evergreens. It is of brighter colours than many of its relatives, being delicate apple green, with a broad stripe along each side of pale green, black along its upper edge, also three narrow stripes of yellow. Early in appearance, too, is the clouded drab (*P. instabilis*), which flies during March and April, a comparatively harmless though abundant species; it visits gardens for the spring flowers, and occasionally deposits eggs on herbaceous plants, but trees are mostly selected. The moth is variable in colour and markings, though it always shows the two discoidal spots and a well-defined pale line near the margin of the wings. In July the caterpillar is about; this is bright green, having a white collar, two indistinct stripes, and numerous dots, also white.

The pretty and delicately formed blossom underwing (*T. miniosa*) looks ill-fitted to face the rough winds and showers of the season when it emerges. Its upper wings have a beautiful band of red on a reddish-grey ground, and the under wings are pinkish and shiny, reminding us of the petal of some flower. This moth occurs chiefly in the South of England. The food of the caterpillar is Oak and Hawthorn; from a hedge of the latter it will sometimes descend, to feed on low plants near. At first it is sociable in habit, parties of about twenty living on a twig under a silken web. When it gets to be an inch long this is rather a showy caterpillar—velvety, the head spotted, and the body marked with pink, white, yellow, and black.

Moths, as a rule, do not congregate—that is, those of the same species, though a troop of various species, large and small, often hovers round the Willow bloom at dusk; but the moth called the Dismal (*Orthosia Upsilon*) has been seen flying near the tops of trees in a shrubbery by scores, or even hundreds, on a July evening. Is it possible they are attracted to the twigs or branches by the sugary secretion of some one of the aphid species? Sombre is its colour, as the popular name implies; on the wings is a figure resembling the Greek capital letter, which suggested the scientific one. When a lad I was walking along the Thames, not far from Kew Gardens, and popped my head into a hole in a Willow tree; to my surprise I found it lined with rows of brown caterpillars, which were evidently those of the above moth. It is their habit to hide during the day singly, or in companies sometimes, under loose bark, in holes, or amongst grass; and after dark they mount to feed, being full-fed towards the end of May.

We come now to a couple of cannibals. The parent moths are not,

perhaps, frequent visitors to gardens, yet we look upon them as, in a sense, our friends; one of the species is in particular, because it is fond of pursuing and killing the caterpillar of that common pest, the winter moth. This is the variable moth known as the dun-bar, or *Cosmia trapezina*, specimens of which show different shades of grey, red, or brown, but always have a bar and two spots. It flies in July, and the chrysalis from which it emerges then has a fine bloom upon it, resembling what we see on some Plums. The caterpillar is abundant in May. It has a stoutish body and small head; is dull green, having five yellowish stripes and numerous black warts, each in a white ring. Oak, Birch, and other trees afford it green food; but small caterpillars are its frequent victims, and of all it prefers those of the winter moth, which have no chance against it, seldom escaping by strength or speed.

The satellite (*Scopelosoma satellitia*) is a larger moth of reddish-brown, with dark lines and white spots. It is a March species, the eggs being laid then on various trees and shrubs. Presumably it eats leaves sometimes, but chiefly subsists on other caterpillars, not even sparing its own species. It is brownish, rather velvety, and striped on the back, living partly concealed under leaves drawn together with silk. Out of this retreat it comes forth to seize passing caterpillars, and if one be handled it exhibits great activity. Occasionally in May these caterpillars quit the trees, and eat leaves or seek prey amongst herbage below. There is also an emergence of the moths in October.

Towards the close of autumn, amongst the species visiting the flowers of Ivy for their honey, or imbibing sugar from the berries of the Yew, is the beaded chestnut, or *Anchocelis pistacina*, a moderate-sized moth, of varying shades of grey and brown, but having the wings crossed by lines, which give the appearance of network. We see this moth in gardens, because the caterpillar feeds sometimes on grasses; but it is also partial to the species of *Ranunculus* or Buttercup, and has been taken in May in cultivated kinds, keeping out of view by day. It is green, striped and dotted with white, the rings showing yellow skinfolds when it crawls; it makes a very compact earthen cocoon for its change.—ENTOMOLOGIST.

PROFITABLE FRUIT GROWING.

(Continued from page 341.)

PRIOR to turning to the second portion of my paper dealing with Grape and Tomato culture, I should like to summarise a few of the most important points that I have placed before you, and which, in my opinion, go to make up success in profitable fruit culture. First, you must have a love for your work, and put your whole heart into it, paying strict attention to every little detail. Begin by making the foundation sound, spare no pains in providing a right rooting medium for your trees—whether they be choice hothouse or outdoor fruit—when you get this, and the abundance of feeding roots that will result, take care of them. Feed well, mulch well, and water well; never dig about them with a spade, but keep the soil firm.

These hints are as applicable to the private gardener as to the market man; and as most of my hearers belong, I believe, to the former class, I may be told that it is all very well to say do this and do that, and do it at the right time, but you must know that in a private place there are a hundred little things that crop up and keep one from doing what they would. Well, I quite believe that. I also quite believe in the maxim, "Where there's a will there's a way." I will point out one little item in your yearly routine of work, which, if altered, would give you more time to do many more needful things. I refer to the common practice of washing all pots before potting, and the method of crocking them by broken pieces arranged into various sizes. I would undertake to transfer 1000 plants from 3 to 5-inch pots in less time than I have seen it take to wash and prepare with crocks a like number of pots. Cinders riddled from the furnaces, or gravel, not only make a more perfect drainage, but the operation can be done in quarter the time. In many places where much pot work is done, the loss of time through this one item alone must be considerable. Clean pots are not necessary for healthy growth. We have grown many different kinds of plants during the last eight years, and never once have washed the inside of a pot, nor ever once found any inconvenience through the balls sticking to the sides; nor could I ever detect the slightest difference in the health of plants potted in clean or dirty pots. I have seen, in one of the largest private places in this country, where every conceivable kind of plant usually grown under glass was potted in this way, and better plants I have not seen anywhere. The saving in this case, for this seemingly trifling item alone, would not be less than £100 per year.

GRAPE AND TOMATO GROWING.

These two go well together. Most houses intended for Grape culture for market have a full crop of Tomatoes the first year, and so on in lesser extent for a few years, until the Vines occupy most of

the space. No other crop of which I know is so suitable or so profitable for this purpose, and perhaps it is owing to this that so many Grapes are grown and prices are at such an unprecedentedly low figure.

I think the clearest and most intelligible way I can lay before you the most important points in connection with the successful culture of these two fruits is to give the details of practice followed in a house where first Tomatoes and then Grapes were grown, and better or more profitable crops of either I have not since met with. This plan will at least have the merit of a faithful record of facts—not theory.

The house in question was a low span-roofed structure, 150 feet long by 15 feet wide. The ground had a fall from both ends to the centre, and the house was built to this rake, which made the water in the gutters run to the centre, where it was collected in a large tank running across the full width of the house. This tank was 3 feet broad and 2 feet deep, and was made by excavating the soil to the required depth, the surface being left a little higher than the level of the surrounding soil. A 4-inch brick wall faced with cement was all that was necessary. Being a wet summer this tank was sufficient for the requirements of the Tomatoes, and I am confident had not a little to do with the ultimate success of the crop. Rain water is the best for all crops. The house was heated by a flow and return 4-inch pipe on each side, or four rows in all, and ran north and south—an aspect I consider best for most crops, especially in Scotland. It was built on part of a field of old pasture. The soil was on the old red sandstone formation, with a hard bottom. It was of good quality, but shallow—less than 12 inches brought the hard red till. The turf was all taken off the inside and a strip outside 2 or 3 inches thick, as it was required for other purposes.

The soil, without any admixture whatever, was simply dug over, but not deeply—4 or 5 inches at most—and the Tomatoes planted. These were brought on in a little forcing house, built to one end of the Tomato house. They were sown in the ordinary soil of the field, with a little leaf mould added. As soon as the seedlings were through the ground they were placed close to the glass, and when large enough were potted singly in 3-inch pots. For this and the subsequent shift into 5-inch pots, nothing was used but loam. As soon as they took to the 3-inch pots, the house was given more air and kept cooler, and the plants placed as near the glass as possible. When ready to plant out, they were thick, sturdy plants, with dark green leaves, and the pots a perfect network of roots. A little fire heat, but only a little—pipes never allowed to be hot—was kept on until the end of May, when it was discontinued until the middle of August. Abundance of air was given on all favourable occasions, and never at any time after the plants were established was the top ventilator quite closed.

The growth at first was slow—so slow, in fact, that it was feared the soil lacked something required by the plant—but, though not gaining much in height, they were thickening in the stems, with broadening leaves of a rich, dark green colour, and rooting freely. They were so sturdy that they stood without support until 2 feet high. Soon the first trusses began to set, and things looked brighter. Up till this stage no stimulant or fertiliser of any kind had been given but rain water, and that rather sparingly. Now a mulching of cow manure was laid all over the border, given a good watering, and covered about 2 inches thick with fresh soil, and made firm. In a few weeks this mulch was one mass of roots, which spread on the surface in some places in a perfect thicket. Trusses of fruit were now setting thick and fast, and so close were they together that in many cases the fruit of the one overlapped the other, many of the bottom trusses having to be kept off the ground by pieces of wood or stone. Another top-dressing similar to the first one was given, well watered, covered with soil, and made firm, which was again soon filled with roots. Afterwards, the feeding was given in the form of a few light dressings of Thomson's Vine and plant manure, and abundance of water when required. The style of training was the single stem, and the plants were set out about 2 feet 6 inches apart each way. At this distance they did not crowd, so no leaves were shortened or removed until they showed signs of decay in the autumn.

The first fruit was gathered about the middle of July, and the last the middle of February, a period of seven months. There was not more than 20 lbs. small, or second quality fruit in the whole crop. They were considered the finest Tomatoes placed in the market they were sent to up to that time, and realised an average of 10d. per lb. wholesale. The average weight of fruit per plant was a little over 11 lbs. This is one way of growing Tomatoes, and it is the way I would strongly advise beginners to start with.

Another way is to grow them with more heat and richer soil. This to a certain extent must be adopted to get early crops, and though heavy crops of fine fruit are often got in this way the risks of failure are greater. It takes more experience and attention, as much forcing does not agree with Tomatoes. The stronger, quicker made, and weaker growth of the plant under this system renders it more susceptible to the attacks of disease than when grown in the hardier and

more natural way I have indicated. An overdose of water at the roots, or the temperature allowed to fall too low—especially at night—will often bring on some of the many troubles to which this plant is subject.

As to the most suitable kinds of soil for Tomatoes, they have been found to do well in many, but a heavy stiff loam gives the best results with least labour and expense, and the worst soil, or the worst rooting medium, is a deep, light loose soil, which, if at all dry, is almost sure to end in failure.

The Tomato delights in a dry airy atmosphere, and it is a good plan to mulch early with manure. Care must be taken, however, never to use fresh manure charged with much ammonia, as I have known several cases where the plants lost nearly all their foliage by this, even though the ventilators were left open. As to varieties, I think there is more in the growing than in any particular brand or strain. Often the same kinds will come quite differently in the various soils and systems of treatment. I have seen seeds sown from a perfectly

FIG. 70.—NARCISSUS WHITE QUEEN.

smooth round fruit, and the produce as rough as clinkers from a furnace. I may state that the variety grown in the house I have described was mostly Sutton's Perfection, and for cool treatment in firm fresh soil I know of no sort that can beat this for a heavy crop. It is not, however, so good a setter in older soils or with much forcing. The best that I know of for this purpose and the first setter I know is Austin's Eclipse. Another good variety is Ham Green Favourite. This with Comet, which is now largely grown for market, is a sufficient and reliable selection for anyone to have.—D. BUCHANAN.

(To be continued.)

NARCISSUS WHITE QUEEN.

THE success that has been achieved during the past few years by the Rev. G. H. Engleheart as a hybridiser of Narcissi has been well maintained so far during the present season. At the Drill Hall on the 12th inst. he annexed the only three first-class certificates given by the Narcissus Committee, and two out of the four awards of merit. One of the handsomest of his flowers was White Queen, of which we give an illustration (fig. 70). It was one of the three that gained the higher honour. As may be seen, it is much in the character of the well-known Sir Watkin, but it is distinct from that universal favourite in colour and slightly in form. The broad perianth segments are glistening white, and the short, broad trumpet pale or sulphur yellow. The whole flower is of great weight and substance, and if it prove as good as Sir Watkin after longer trial anyone will be safe in predicting for it a great future.

ROSE SHOW FIXTURES IN 1898.

- June 15th (Wednesday).—York.*
 „ 16th (Thursday).—Colchester.
 „ 23rd (Thursday).—Bath (N.R.S.).
 „ 25th (Saturday).—Windsor.
 „ 28th (Tuesday).—Southampton,† Sutton, and Westminster (R.H.S.).
 „ 29th (Wednesday).—Canterbury, Croydon, and Richmond (Surrey).
 „ 30th (Thursday).—Eltham, Gloucester, and Norwich.
 July 2nd (Saturday).—Crystal Palace (N.R.S.).
 „ 5th (Tuesday).—Harrow and Hereford.
 „ 6th (Wednesday).—Farningham, Hanley,† Redhill (Reigate), and Tunbridge Wells.
 „ 7th (Thursday).—Woodbridge.
 „ 8th (Friday).—Ulverston.
 „ 9th (Saturday).—Manchester.
 „ 12th (Tuesday).—Wolverhampton.*
 „ 13th (Wednesday).—Ipswich and Newcastle-on-Tyne.*
 „ 14th (Thursday).—Halifax (N.R.S.), Canterbury (Hospital Fund) and Helensburgh.
 „ 21st (Thursday).—Sidcup.
 „ 26th (Tuesday).—Tibshelf.

* Shows lasting three days. † Shows lasting two days.

The next list of fixtures will appear early in May. In the meantime I shall be glad to receive the dates of any Rose shows, or other horticultural exhibitions where Roses form a leading feature, for insertion in that list.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

AMERICAN RAISED ROSES.

THE question is frequently put to me, Why are there not more American seedling Roses of merit raised? The reply to this may be given from several standpoints, two or three of the most important reasons being as follows:—

The first is, that in a general way the process from the fertilisation of the flower till the plants bloom takes too long for our ideas of getting the desired results. For proof of this we have only to turn to the Carnation and Chrysanthemum. Here it takes only a few months, six to nine at most, to determine what our efforts have produced, and as a result we have plenty of sterling varieties of both these flowers continually being offered. But with the Rose it is quite different, as it takes three or four times as long to get any indication of what the results are likely to be. Then if out of several hundred seedlings there should happen to be one or two that are promising on first blooming, it takes a much longer time to work up sufficient stock to give a fair trial to test the many desirable qualities, such as colour, size, free blooming, healthy, vigorous constitution, distinctiveness, and several other qualities necessary to make it worth putting on the market, and then when the raiser has satisfied himself on all these points it takes a still longer time to work up sufficient stock to enable him to offer it for sale.

This, of course, is presuming that the first blooms hold their characteristics good continuously, which often happens to be the reverse, then a double disappointment is the result. This long waiting and often final failure to obtain the desired result deters many from trying again after their first attempt. On this score it may not be out of place to mention the fact that many seedling Roses do not show their full character the first time of flowering; often the most promising at the first are the most disappointing later on, and others with less attractiveness on first blooming turn out much better with further acquaintance. Thus there is always a great amount of uncertainty attached to it which deters many from taking up this branch of our business that otherwise would and could do so with great advantage to horticulture.

The next factor in this case is that so few of our rosarians in this country feel they can afford the time necessary to pursue the subject with that minute detail and study necessary to make it a success. This is particularly true of the commercial florist generally. No one, I think, will dispute the fact that this class of men have all they want to do to manage their business successfully and pay their way, having no time for indulging in anything that does not promise quick returns.

But this does not apply to many amateurs who could, if they would, take up the raising of seedling Roses, and find a great amount of pleasure in the occupation. I do not mean by this that anyone with just enough knowledge of horticulture to know what a Rose is could do so; but those who have made a study of flowers for their own pleasure, and who often become expert judges of the different qualities necessary in any flower, could select the parents having the best developed qualities, which, when blended, would produce the best and most distinct forms desired.

No country to-day offers the inducement that ours does for anything that is really an improvement in Roses. The field is a broad one, and those having the time and means to devote to the subject need have no fear of over-production, or of not finding in our Republic an appreciative people willing to endorse a really good thing, even though it be a queen.—JOHN N. MAY (in "American Florist").

[We did not know that even in America Carnations and Chrysanthemums could be raised and flowered in six to nine months after fertilisation was effected.]

APRIL CHARACTERISTICS.

APRIL is one of the most interesting of all seasons, because it is essentially the period of hope. It has been described—not without expressiveness—as “the month of smiles and tears.” Of late the latter have greatly predominated, most fortunately for the horticulturist; for previously, while frost prevailed during the night, the strong sunlight could only do damage among his treasures during the day. Then the vegetative capability of Nature was dormant; now, since the rain has fallen so beneficently, the fair green earth has visibly gladdened, and millions of Daisies, with “silver crest and golden eye,” are brightening the fields. In the glens and by the waysides those wild flowers that make late spring so attractive are beginning to appear. The blossoms of the Gorse are marvellous in their varying golden colours, reminding me instinctively of the beautiful hue of that queen of Noisettes, the *Maréchal Niel* Rose; and the Blackthorn is assiduously pouring forth daily its far-shining masses of snow-white flowers. I do not know if, within the boundaries of Nature, it would be possible to find fairer revelations than these.

Our gardens also, even at this early period, have much fascination. We are already on the confines of the bloom of the *Auricula*, one of the most fragrant attractive of all flowers, and the charming *Lily of the Valley* is gradually unfolding, in sheltered recesses, its capabilities of growth. *Narcissus ornatus*, contemporaneously with those great Daffodils, *Sir Watkin* and *Horsefieldi*, is flowering earlier than usual this year. A highly effective companion of these, by reason of its brightness, is *Narcissus odoratus*, also called the *Campernelle Jonquil*.

On many fruit trees there is already an abundance of blossom, especially on certain varieties of the *Almond* and the *Plum*. The *Cherries* also are covered with flower buds, almost ready to expand. The *Irish Peach Apple* is already revealing the bright colour of its flowers, while *Duchess of Oldenburg* is almost equally advanced. Rose trees, so long retarded by late pruning and the influence of the frost, inspired by genial rains and consequent mildness, are beginning to exhibit their brightly coloured shoots. *Oriental Lilies*, particularly such forms as *Lilium giganteum*, *L. auratum*, *platyphyllum*, and *L. Henryi*, are growing with great rapidity; while *Browni*, *Szovitzianum*, and *Washingtonianum* have not yet appeared. But their period of activity will soon be at hand.—DAVID R. WILLIAMSON.

HINTS ON POTTING.

POTTING, or giving fresh soil and increased root room to plants, is divided into two well-defined methods—namely, repotting and potting on. The former method is carried out when plants do not require larger pots, but yet need fresh soil or clean drainage.

Palms, numerous Ferns, Zonal Pelargoniums, and many hardwooded plants, the rooting medium of which may have become sour, occasionally need turning out, the roots examined and pruned to healthy parts, old inert soil carefully picked away, as well as choked drainage, afterwards placing the plants in similar sized pots. In some cases, however, turning the plants completely out of the pots may not be necessary or convenient, but simply the loose inert soil dug out down to the roots, filling up the space with fresh material. This is termed top-dressing, and is adopted chiefly where roots are not abundant in the surface soil, or where the loss of a few along with the impoverished material is not of much consequence. The added soil should be pressed firmly down. Top-dressing is effective for clearing the surface of mossy growths which accumulate by repeated waterings.

All softwooded plants in small pots, and needing to be increased in size, must be potted on as a fair quantity of roots reach the sides of the pots and begin to appear through the drainage. *Fuchsias*, *Pelargoniums*, *Begonias*, *Tomatoes*, and *Chrysanthemums* all require special attention at this season, in order that the plants do not become root-bound, until they have reached the size pots in which they are to flower.

There are a few small but important details to be attended to when potting which help largely in insuring the success of the operation. Before proceeding to pot any plant into a larger size it is imperative that the roots and soil be moist, but not wet, so that the soil is sticky and greasy, rendering it unsuitable for the operator to handle. Plants to be potted, therefore, should be examined some hours previously, watering those well which may be dry.

The compost for potting is the next consideration. It must be composed of the various ingredients required in their proper proportion, and when the materials are properly mixed the whole ought to be in a sufficiently moist condition. If afterwards it becomes dusty and dry before it can be used sprinklings of warm water and several turnings will restore it to a healthfully moist state.

The fresh pots to which the plants are to be introduced must be thoroughly clean and dry. Plants in a young state requiring several shifts, specially need this attention, as in pots that are dirty inside, the young roots will adhere so fast that a difficulty will be experienced in turning the plants out with unbroken roots, which is injurious if the balls of soil and roots have to be dragged from the pots.

The crocks employed in draining require also to be clean and dry. The crocks ought to be carefully placed in the pots, and not more numerous than absolutely necessary, some quick-growing plants only needing one well placed crock over the hole of small pots. The amount of drainage in larger pots does not depend on the quantity placed in, as upon its systematic arrangement, for effectiveness. These details are applicable without exception to all plants when potting.—E. D. S.

THE ROYAL GARDENERS' ORPHAN FUND ANNUAL DINNER.

THE annual dinner of this charitable Institution was held, as announced, at the Hotel Metropole on the evening of Wednesday, the 20th inst. Fully a hundred sat down, and amongst other gentlemen well known in the horticultural world were Sir Trevor Lawrence, Bart., and W. Marshall, Esq., Mr. J. Smith of Mentmore, Mr. M. Gleeson of Stanmore, Mr. Geo. Wythes of Syon, Mr. H. J. McLeod of Dover House, and Mr. Geo. Reynolds of Gunnersbury Park, with the genial Curator of Kew, Mr. Geo. Nicholson. English botanists were represented by Mr. W. B. Hemsley of the Kew Herbarium, and the trade by Messrs. N. N. Sherwood, M. J. Sutton, L. Sutton, P. Kay, T. Rochford, H. B. May, H. Turner, E. M. Seegar, H. J. Jones, R. Cannell, and P. R. Barr. Chas. E. Keyser, Esq., of Aldermaston Court, Reading, presided.

After the viands had been properly discussed the Chairman rose to propose the usual loyal toasts of "The Queen" and "The Prince and Princess of Wales and the rest of the Royal Family." Her Majesty, he said, was interested in everything that interested her subjects, and he thought, therefore, that horticulture had a special claim upon her. The Princess of Wales, their Patroness, was probably the most popular lady in the land next to the Queen. The Prince astonished everyone by the amount of work he got through, and indeed the whole of the members of the Royal Family did their best to identify themselves with all classes of society. He hoped that loyalty would long be a characteristic of Englishmen.

These toasts having been done due justice to, the Chairman again rose to propose the toast of the evening—"The Royal Gardeners' Orphan Fund." He said he felt some diffidence in coming amongst them that evening as their Chairman, seeing that he was following a number of eminent noblemen and gentlemen. His audience, too, knew fully as much concerning all matters connected with the Fund as he himself. They knew it was started in 1887 in commemoration of her Majesty's Jubilee, and that there were now funds invested to its credit amounting in value to over £10,000. The work accomplished by the Fund was an estimable one, for it was charity in the best sense of the word, those who had been fortunate in horticulture combining to alleviate the distress of those who had been unfortunate, thus often enabling the mother of a family, in the absence of the breadwinner, to tide over the critical time. He thought the Fund was not so well known as its sister society, the Gardeners' Royal Benevolent Institution, but he hoped to see its sphere of influence much enlarged in the near future. He coupled with the toast the name of Mr. N. N. Sherwood, their esteemed Treasurer, who had been connected with the Association from the commencement.

The toast having been cordially received, Mr. N. N. Sherwood rose to reply. After thanking the Chairman for associating his name with the toast, he said that they had much to be thankful for, since the Fund had met with a considerable share of prosperity from its inception. He regretted to say, however, that last year the annual subscriptions showed a slight falling off, and he made a strong appeal to all to open their purse strings. He suggested that the children of noblemen and gentlemen owning large estates should be encouraged to save for the Society, the money thus obtained going to establish funds to be called after the name of the houses from which they came, or of the children supplying the money. He hoped to see in the near future all the orphans who came up for relief elected, and that they would not have to turn some of them away as they were obliged to do now.

The toast of "Gardeners and Gardening" was proposed by Mr. Martin J. Sutton, who coupled with it the name of A. W. Weeks, Esq. He said that his own province was agriculture, but he was sure that farmers would have to take a lesson in thorough and careful cultivation from the gardeners if they were to make their land pay. Mr. Weeks responded, and paid a high tribute to the uprightness and trustworthiness of gardeners. They were, he said, often entrusted with goods to the value of many thousands of pounds, and yet he had never known a dishonest gardener. He thought this was largely due to the fact that their employers treated them well.

Mr. Marshall invited the assembly to drink to the health of their worthy Chairman, who had honoured them with his presence that evening. No half-hearted response was made to this, and Mr. Keyser, when he rose to reply, received another cordial greeting. He assured the company that he felt it an honour to be there, for he took a deep interest in everything relating to gardening. He had given his representative at Stanmore (Mr. M. Gleeson) and his representative at Aldermaston (Mr. A. Galt) the opportunity of showing what they could do in competition, and he had done this with a view to help the grand exhibitions of horticultural produce now to be seen in this country. In conclusion, he assured them that he should not be satisfied unless his efforts brought in an accession of interest to the Society, and thanked them for their kindly reception.

"The Press" was proposed by Mr. R. Dean, who endeavoured to impress upon his hearers how much the Society owed to the horticultural press in particular. He coupled the name of Mr. Geo. Gordon. That gentleman, in replying, averred that the horticultural press was unanimous in endeavouring to assist the Fund, and they had felt it to be their duty to keep its claims persistently before the public. He called attention to the revenue that might be obtained for the Society by holding concerts and dedicating the proceeds to the good cause.

When the evening's subscriptions were announced it was found that they amounted to £515 in all. Included in this total there were, besides a large number of smaller sums, large amounts from the following sources:—C. E. Keyser, Esq., £116 16s.; N. N. Sherwood, Esq., £58 14s.; Mr.

G. Reynolds, £32 18s.; Mr. Assbee, £63 6s. (including £5 from Mr. Rochford, £5 from Mr. M. J. Sweer, and £5 from Mr. J. Walker); Baron A. de Rothschild, £10 10s.; N. M. Rothschild, Esq., £26 5s.; M. J. Sutton, Esq., £25; L. J. Sutton, Esq., £25; A. W. Sutton, Esq., £5; S. M. Seegar, Esq., £19 19s.; A. W. Weeks, Esq., £16 5s.; W. Robinson, Esq., £10 10s.; Mr. H. J. McLeod, £10 16s. 6d.; Mr. J. B. Stevenson, £6; Dicksons, Ltd., Chester, £5, and Mr. H. J. Adams, £5 5s.

Mr. Keyser subsequently announced that a number of his friends to whom he had made appeals were abroad, and he hoped to be able to obtain from £50 to £100 more than that subscribed, which statement was received with much applause.

During the evening some capital songs were contributed by Miss Gertrude Snow, Miss Emily Foxcroft, and Mr. Herbert Schartau, whilst a humorous recital, given by Mr. Harry Hudson, was much enjoyed. The tables were prettily decorated with Daffodils and other flowers, furnished by Messrs. Barr & Sons, and other nurserymen. They were very tastefully arranged by employes of Messrs. Wills & Seegar of Onslow Crescent, S. Kensington.

The meeting broke up with a vigorous rendering of "Auld Lang Syne."

TOO MUCH OF A GOOD THING.

THIS proverbial saying is doubtless admitted universally. Nature provides bountifully the yellow colour in flowers, and I should think somewhere not far from one-half of all "wild flowers" are yellow, and most flowers are "wild" somewhere. By administering artificially to this copiously existing colour, as we do with a vengeance in Daffodils, we seem to get too much of a good thing, and some balance is necessary.

Has anyone seen an attempt made in the naturalisation of flowers on principles to repress the uniformity of yellow shades? Everybody knows Daffodils, but not one in a hundred knows *Anemone apennina*, the original pretty blue variety, obtainable at a ridiculously low price by the hundred and thousand. It will increase naturally, and does not want disturbing for a generation, if ever; simply leave it alone. To see it flowering on sunny days in April is truly delightful wherever naturalised in masses. Such should be placed among Daffodils, when I feel sure of the extreme satisfaction that will be provided. Plant in September-October, and where ground is heavy, place the dry tubers in some sandy mixture. There is the white variety besides, *A. a. alba*, of newer introduction, and equally pretty.

After yellow we have white, blue, and red flowers following naturally in this order of frequency. It is sometimes possible to improve upon Nature, and hence the suggestion. If the unsurpassable and brilliant crimson *Anemone fulgens* be placed among *Anemone a. alba*, the result might charm many flower-lovers. For other charming blue flowers to associate with the preponderance of Daffodils, we must not forget *Scilla sibirica* and *Chionodoxa Lucilæ*.—H. H. R., *Forrest Hill*.

FLOWER AND GARDEN PICTURES AT THE NEW GALLERY.

BEING at the New Gallery on the Press Day, I could not but be struck with the very large proportion of the exhibits which have to do with gardens and flowers. Thus in No. 11 Miss E. Stewart-Wood has a pleasing picture of wild Roses; and at No. 32 Mr. Alfred Parsons, A.R.A., has what is unquestionably one of the gems in the Gallery in his picture of Sweet Williams, wherein we are introduced to a pathway, in which the sun shines through the bushes and flowers which bank each side. The picture is marvellously true to nature, and one of the best of its kind ever exhibited. At No. 45 Mr. Anderson Hayne shows a very pleasant and solidly painted cottage garden; at No. 47 Mr. A. F. Hayward introduces the visitor to some red Chrysanthemums; and at No. 50 Mr. Toystan Hetherington has a capable picture of a garden in Surrey.

Under the title of "At Eventime they Pass Away," Mr. J. Fitz-Marshall at 53 shows a clump of *Convolvuli* just at the time when they are closing up for their night's repose. At No. 56, Mrs. Kate Pengini has the flowers that bloom in the spring; at No. 93 Mr. Gaetano Meo has a pretty and well-executed view of an old Devonshire orchard, redolent of cider Apples; at No. 131 Mr. Edward Clifford introduces us to the ancient garden of Moreby Hall, York, wherein we are thrown back, as it were, into the past century; at No. 133 Mr. Robert Bateman has a spray of Carnations, well executed, with the peculiar title of "Carnations and Love in a Mist;" at 138 Mr. A. F. Hayward has a picture of Chrysanthemums; while at 139 is a very satisfactory view of a garden by Mr. Arthur Lucas, and next is another very fine flower piece by Mr. Parsons, the subject being Larkspurs and Roses, which is an admirable companion picture to his Sweet Williams referred to above. At 144 Mr. A. F. W. Hayward has a nice collection of Japanese Anemones; at No. 151 Mrs. Nora Hartley has a group of Roses; and at No. 157 Mr. Lance Calkin gives us "In a Garden Gay."

Many will view with kindly interest the Church allotment, Suffolk, of Mr. Toystan Hetherington, shown at No. 166, and at 193 Mr. Bateman has the *Pæony* pictorially limned. At 204 Mr. Hayward has a group of Azaleas, which, with a view of a Paris garden, shown by Mr. Bernard Harrison at No. 315, which with a clump of Roses by Mr. Hayward at 425, completes the sum total of those pictures which may reasonably be expected to possess a particular interest for gardeners and floriculturists. Altogether the exhibition is a good one, and well worthy a visit.—WM. NORMAN BROWN.

WEATHER IN LONDON.—The second half of last week was much colder than the first portion. On each day the wind was somewhat searching, and occasionally a little wet could be felt in the air. There was a very heavy dew on Saturday night, and on Sunday the sun shone brilliantly, but it became cool again towards evening. On Monday it was cloudy and cold, but no rain fell, but on Tuesday the conditions were changed, and a welcome shower fell in the evening. On Wednesday it was dull and warm, but no rain fell up to midday.

WEATHER IN THE NORTH.—Seasonable, and occasionally very fine weather has marked the whole of the week ending on Tuesday morning. The 21st, and the former part of Sunday were delightfully pleasant. Showers have occurred throughout; the moist atmosphere and hazy sunshine have given a great impetus to vegetation, and the country has the appearance of mid May. The cuckoo and the swallow are reported from W. Perthshire.—B. D., *S. Perthshire*.

FRUIT TREES IN S.W. SCOTLAND.—In this district of Scotland there is at present a splendid display of blossom on Plum, Cherry, Almond, and Pear trees; and some of the Apple trees are already exhibiting their beautiful flowers. Among Plums, The Czar, the Early Rivers, and Denniston's Green Gage are especially impressive. It is evident that fruit trees have much benefited by their rest of last year, which was well earned after their memorable effort of the previous season. They were also greatly favoured by the comparative mildness of the winter and spring. At present atmospheric influences are extremely favourable to the development of the blossom into the fruit, brilliant sunshine alternating with soft and genial showers.—DAVID R. WILLIAMSON.

DEATH OF THE REV. H. G. JEBB.—We regret to announce the death of the Rev. Henry Gladwyn Jebb, of Firbeck Hall, which occurred at Sheffield on the 19th inst. For several years Mr. Jebb suffered much from his eyes, and had undergone operations with benefit. He came to Sheffield on the 13th inst. for further treatment, but unfortunately he had already contracted influenza, and succumbed as stated. Mr. Jebb was born in 1826, and was privately educated at Stamford. He proceeded to St. John's College, Cambridge, of which he was an exhibitor. He graduated B.A. in 1851, and M.A. in 1872. He was also F.S.A. Being an ardent student the deceased became acquainted with many distinguished men, and his travels abroad extended materially his sphere of knowledge. On several occasions learned societies have enjoyed his hospitality, and have been privileged to view some of the many treasures he was able to show. He was a man of high literary attainments, with a wonderfully retentive memory, and his knowledge of Shakespeare was remarkable. He was much interested in horticultural matters, especially Roses, as is Miss Jebb, who is a member of the National Rose Society. He leaves a widow, one son, and two daughters. His son is Mr. H. J. Jebb, J.P. The funeral took place at Firbeck on Friday.

FRUIT PROSPECTS AT LIVERPOOL.—Judging from present appearances we ought to have an abundant crop of fruit of all kinds this season, provided the weather keeps favourable for the next fortnight or so. Pears, Plums, and Cherries are in full bloom, and the pink of the Apple blossom now slowly unfolding is charming to look upon. We want warm showers, as the rainfall has not been over-abundant since the year came in. Fortunate are those who have been able to give some of their trees a copious supply of liquid manure previous to their coming into blossom, as this system only needs to be tried to see the beneficial results in the setting of a crop of fruit. Whilst making a journey through a portion of Cheshire a little more than a week ago I was much struck by the wonderful promise for Damsons. Along the hedgerows by the way-side and at the farmhouses the trees were literally laden with sheets of white such as is seldom seen, and as the Damson crop last year was almost the worst on record, it will be little short of a calamity if the supply of this delicious fruit should again be cut short by a spell of bad weather. Of course it is too early as yet to know the extent of the crop of various kinds of fruit, but I hope to be able to send a report later on.—R. P. R.

FLORILEGIUM HAARLEMENSE.—The excellence of this ornate work is splendidly maintained in the sixth number, which has just come to hand. The plates are beautifully executed, while the letterpress (in four languages) is clear and sound. The illustrations comprise Hyacinth King of the Blues; Tulips La Reine, Yellow Prince, and Silver Standard; and Chionodoxa Lucilæ and *C. sardensis*, with *Scilla sibirica*.

DEATH OF MR. J. S. ROBINSON.—We regret to record the death, on the 21st inst., of the above gentleman, who was so well known in Worksop and the neighbourhood. The deceased was only thirty years of age, and he will be much missed, not only as a sportsman, but for the keen interest he manifested in horticultural matters. One of the finest shows that has been held in Worksop was in grounds that Mr. Robinson lent, while he was also a believer in allotments, and let much of his ground for this purpose, both at Worksop and Nottingham.

A "LOAD" OF POTATOES.—In some districts Potatoes are sold by the load. Will you or any of your readers kindly give in your next issue what number of pounds there are in a load? and greatly oblige—E. C. K. [For anything we know to the contrary, a "load" may vary in weight in different counties, as a peck does; and if so, local custom must be adhered to. Ten sacks, of 2 cwt. each, represent a load in some districts, or 2240 lbs. Perhaps some of our readers may be able to supply information on the subject differing from that we have given. We know of Potatoes being sold at 14 lbs. to the peck, 16 lbs., and 21 lbs. respectively.]

WEATHER AND PROSPECTS IN GUERNSEY.—Since the notable storm we had on March 24th and 25th, Dame Nature has been on her best behaviour. After a steady downpour of rain, followed by sunny days, everything both indoors and out has made wonderful progress. A few parcels of Tomatoes have been sent away, and by the first week in May the crops will be ripening freely. Melons, Figs, and Grapes are also being shipped, and so far realising fair prices. Broccoli paid very well till the large consignments from Cornwall forced down the price in nearly every market. French Beans have paid well. Flowers also have been in good demand. Pear and Plum trees are in full bloom and promise a heavy crop. Grass is abundant, and the prospects of the season seems to be fairly satisfactory.—X.

GARDENING APPOINTMENT.—Mr. Alfred Bishop, gardener to Robert Burrell, Esq., Westley Hall Gardens, Bury St. Edmunds, has been engaged as gardener to Sir Humphrey de Trafford, Bart., Hill Crest, Market Harborough. It may be stated that Mr. G. A. Bishop received the notification of his acceptance for the position and of the Government appointment at Bermuda, as announced last week, at practically the same time, choosing the latter. His brother is accepted for Hill Crest in his stead. Some gardeners have difficulty in finding one situation, while Mr. Bishop, after long waiting, had the chance of two good ones at the same time. Really good men need not despair, though we know of some who find it weary waiting for positions which they could most creditably fill.

INTERNATIONAL HORTICULTURE.—I have been looking over the long and somewhat monotonous reports printed in the gardening press of the recent great horticultural show in Ghent. I do not say reading them, because to me, as to nine-tenths of readers, the reports have little special interest. Still enough was seen to show that whilst a grand International Show was held, yet there seemed to be in association with it very little of international courtesy of an official kind. Of course the British gentlemen who attended were most kindly welcomed and hospitably treated; that would be assured, but I could not gather that anyone of these were present as a representative of our Royal Horticultural or any other important horticultural society. Possibly no one was so invited. I do not know. Still it is difficult to avoid an expression of regret that such a gathering of continental horticulturists as was seen at Ghent had not been added to by some two or three official representatives of British horticulture. I notice that the President of the National Horticultural Society of Paris, so described at least, was present, although the title is rather a misnomer, and possibly it should have been of "France," to make the society national. In any case France was thus officially represented, and Great Britain was not. That seems to be matter for regret. It is not less matter for regret that great international horticultural shows seem to be held now only on the Continent, and not in Great Britain. Is it not possible for us to hold one in London at least once in ten years? Surely so long as there is the Crystal Palace, and its splendid area and grounds, there is a place unequalled for such a show in the whole world. Whilst there is yet time why not set about organising a grand international horticultural exhibition here, to inaugurate in 1901 the commencement of what may be, we trust, for horticulture the glorious twentieth century?—A. D.

— **IMPROVING HASTINGS.**—A winter garden will probably be one of the attractions at Hastings in the near future. It is proposed to erect a handsome building that will be capable of holding four thousand people; the estimated cost is between £30,000 and £40,000.

— **SOWING HERBS.**—A thought must be given to the culture of the most useful herbs, so that a supply can be obtained when any kind is asked for. Those which may be grown from seed sown now are Thyme, Sage, Marjoram, Summer and Winter Savory, Fennel, Rue, Balm, Wormwood, Horehound, and Hyssop.—E.

— **ROYAL METEOROLOGICAL SOCIETY.**—The monthly meeting of this Society was held on Wednesday evening, the 20th inst., at the Institution of Civil Engineers, Mr. F. C. Bayard, L.L.M., President, in the chair. Major H. E. Rawson, R.E., read a paper on "Anti-cyclonic Systems and their Movements." The Hon. F. A. Rollo Russell described the results of observations which he had made on haze and transparency during 1897. He found that the greatest clearness occurred with winds from the westward, and the least clearness with winds from the eastward. The highest mean visibility was twenty-four miles with west winds, and the lowest mean visibility was 10.6 miles with north-east winds.

— **NARCISSI VARIATIONS.**—Does the double white Narcissus incomparabilis, commonly called Orange Phoenix, revert to the double yellow, called Butter and Eggs? There were beds in my garden of both Sulphur Phoenix, Orange Phoenix, and Butter and Eggs. In course of transplanting the whole of what is now tallied Orange Phoenix turns out to be Butter and Eggs, but the Sulphur Phoenix has retained its form and colour. The old incomparabilis is unstable in form, the single coming sometimes double, and then reverting again to single. Orange Phoenix was probably a sport from the double yellow, and its loss here is possibly due to reversion, and not to careless transplanting. I should be glad to know the experience of others as to its constancy.—ROSS-SHIRE.

— **UNAPPRECIATED FELINES.**—At Woolwich, on Saturday, among the applicants for magisterial advice was a person who stated that he had half an acre of nursery ground surrounded by about twenty-five houses. The place was literally overrun by cats that destroyed everything that he tried to grow. His Dahlias, Chrysanthemums, and other plants were torn up by them nearly as soon as planted, and he wished to know what steps he could take to protect himself from their ravages. Mr. Paul Taylor: I have no control over cats (laughter), and I cannot suggest any remedy for your grievances. The applicant retired, evidently much disappointed at the magistrate's inability to help him.

— **WORKING HORTICULTURAL SOCIETY.**—At the commencement of the present year this Society decided to remove the radius limit, and admit to membership anyone who wished to join them. The result so far is satisfactory. New life and energy appear to have been infused into its members, judging from the monthly meeting held on Thursday last. The attendance was above the average, and great interest was taken in an admirable paper on "Hardy Flowers" by Mr. Scaplehorn of Messrs. Geo. Jackman & Sons. The exhibits staged for special prizes were numerous and of excellent quality, the principal one being for a collection of cut flowers. Mr. Needs gained the first prize with a beautiful display of *Lilium Harrisii*, *Narcissus*, and *Tulips* in such excellent form that the Judges awarded the Society's certificate in addition to the prize. Mr. G. Carpenter of Byfleet was a good second, a lovely bunch of *Maréchal Niel* Roses being admired by all present. Mr. J. W. Jones exhibited a beautiful collection of *Narcissus*, for which a certificate was also awarded.—VISITOR.

— **THE DEFICIENCY OF RAIN.**—A serious feature in the weather has been the great lack of rain, coupled with the presence of a very dry wind from the north-eastward. In London the total fall for the present month has been less than half an inch, or very little more than a third of the average for the time already expired. During the previous six months the total rainfall amounted to only 57 per cent. of the average, an unusually small proportion for so extended a period. In two months out of the six the total was considerably less than half the normal, while in one month (October last) it did not exceed one-sixth of the normal. In many other parts of our southern counties the weather since last summer has been quite as dry as in London, and in the rural districts the springs are in most cases alarmingly low. This month the western and northern districts appear to have fared better than other parts of the country. Over the North of England the rainfall has not been far short of the average, while at some places in the West it has been slightly in excess. In Ireland and some portions of the West and North of Scotland there has been a rather considerable excess.

— **WHAT THE SOUDAN PRODUCES.**—Here is an extract from a letter written home by a soldier now in the Soudan that helps us to realise something of the physical discomforts our men are called upon to endure. It was, says the writer, rather a different place from what he had expected. He thought the Soudan would be all sand and Dervishes, but he found that, although there were Dervishes about, the ground seemed to be made up of "one-third sand, one-third flies, and one-third fleas." It does not sound very pretty, but it is not far out. We think the Soudan would be an admirable place to test the efficacy of insecticides.

— **DOUBLE PRIMROSES REVERTING.**—There are conditions of culture or something else which seem apparently to induce some double Primroses to revert to the normal single form. Some thirty years ago there was put into commerce a lovely single crimson Primrose, then called *auriculæflora*. It had a golden centre, a thrum eye, and was perfect in form. This was found in a garden at Shirley, Southampton, and its origin was lost in oblivion. I regarded it as a reversion from the double form of the famous and beautiful double crimson. Later I met with a small reversion to single from the double lilac, at Feltham, but just recently I saw quite a stock of single reversions from that popular double at Hackwood Park, where every flower was a perfect single, and very beautiful too. The clumps were large, and had been growing beneath some Nut trees for several years. I have advised that these clumps be lifted, divided, and replanted on a north border, just to see whether higher culture may produce doubleness or not.—A. D.

— **OLD READERS AND WRITERS.**—I am very much obliged to you for your information re Sir Watkin Narcissus bulbs on page 314. May I say that you have very few older contributors to "our Journal" than myself? In my first number of the "Cottage Gardener" you have a supposed set-to with Miss Penelope Pomeroy about the Journal after the duty was taken off paper. I allude to August 20th, 1861. I suppose nearly all of your readers of those days have joined the majority, but I am pleased that "Upwards and Onwards" is still able to wield his pen. I have fifteen years of "our Journal" bound volumes, and since 1866 I have the whole of the numbers packed and tied in half yearly parcels. When I have occasion to look into the back numbers of the sixties I remember the pleasure I had in reading the letters of Messrs. D. Beaton, "D., Deal," George Abbey, W. Keane, J. Robson (who was a Northumberland man), "Nickerbocker," and many others. You are very welcome to publish this if you think well to do so.—G. C., pp. GEORGE CHARLTON, jun., *Morpeth*. [We like to hear from old friends. Many readers in the early sixties have naturally passed away, but we are glad to know that many still remain, including three of the writers mentioned. We hope our correspondent may have several half yearly parcels to tie, and that the junior will follow the good example of the senior in cherishing his "Journal."]

— **BEDDING DESIGNS.**—It is very apparent, from the pamphlet bearing the title at the head of this note, that Messrs. H. Cannell and Sons, Swanley, the publishers, will do all they can to prevent formal bedding from dying out. In the booklet which we now have before us sixty designs for beds are given, together with lists of plants that will be found suitable for each one. Several would come within the category of carpet bedding, while others embody suggestions for the spring and summer adornment of the flower garden. To those who wish fresh ideas for their bedding, the pamphlet, for which the firm charges 6d., should be of material assistance. Relative to the making and planting of carpet and other beds, Messrs. Cannell & Sons say, "The main thing in carrying out carpet bedding effectively is to decide on the design for next year, and prepare coloured drawing and plants accordingly. When the time comes for planting, dig deeply and tread down moderately firm; take all levels, and draw and stake out just the design required. First make sure of the centre, avoiding hollows, and if the lines are to be straight they must be exact, while if curved they must not have straight parts, neither must there be any sudden or sharp bends; avoid all these, or the whole beauty of the bed will be lost for the season. When planting make sure that the plants are as near one size as possible, for to a great extent the beauty of the bed depends on this regularity of arrangement. Be sure and provide sufficient plants, that they may be planted thickly, so as to give effect at once, particularly in the case of *Coleus* and *Alternantheras*—in fact, when sparingly planted they invariably prove a failure. As soon as the plants commence growing it will be necessary to clip or pinch all long straggling shoots away; after this comes the main thing—that is, every plant allowed to fill its allotted space and no more. The various lines must be kept well defined; should one plant be permitted to outgrow its neighbour, the whole will become confused and all beauty gone; therefore strict attention to trimming must now become the whole and sole point of making bedding attractive."

THE HISTORY OF THE SOILS OF THE BRITISH ISLES.

I OFFER for your acceptance some notes by my late father on a subject of which he had made a special study during his long term as head gardener at Belvoir Castle, with the hope that they may be of interest to the readers of the *Journal of Horticulture*. They are as follows:—

The vigour and complete development of a plant is due very much to the soil from which it has sprung. The plants we cultivate—whether for food, for economic, or decorative purposes—originated in soil more or less marked by fertility; the compact and impervious soils we call clay do not in their primitive state invite or support a superior race of plants, neither are such found in barren sands; we may thus learn our first lesson in the application of soils to cultural purposes, that a soil naturally fertile supplied the conditions that first promoted the development of those properties in a plant that made it valuable to us, and to secure its healthy progress we must in cultivating it continue to supply it with earthy matters that possess the constituents of fertility.

In treating of soils we have first to seek in the geological history of the country an explanation of their origin; and, secondly, information as to their general or local occurrence. The diversity in the character of the superficial covering of earth of this country corresponds with the variety exhibited in its rocky structure. In the comparatively limited area of the British Isles we have examples of nearly all the great geological formations of the world; we possess, therefore, advantages which do not belong to many other countries of similar extent.

Glancing at a geological map of the British Isles, we find a development of igneous rock, trap and granite, in the extreme north and south, some eruptive masses in the centre of the country, and more extensive examples in the west. Next in succession appear the Cambrian rocks in Wales and Cumberland. The silurian formation is represented in the elevated land of Shropshire and in Wales. The old red or Devonian has a considerable expansion in Scotland, Herefordshire, and Cornwall. The carboniferous, which includes the coal measures, extends from North Britain through Northumberland, Durham, Yorkshire, Nottingham, Leicester, Derby, and Wales. The permian is found in the north, traversing Northumberland, Durham, York, and Derby. The new red sandstone occupies a very important central position, extending from Hartlepool on the Tees to the Severn in Gloucester, and a less important development in the south of England. The oolite, in its several divisions, extends almost uninterruptedly from Whitby in Yorkshire to Lyme Regis in Dorsetshire. The Wealden, or fresh-water and estuary formation, is seen characteristically in Sussex. The cretaceous or chalk formations run along the borders of the north-east and eastern counties, from Yorkshire, and striking through Berkshire, Sussex, and Hampshire, with Dorsetshire form the South Downs. The tertiary formations—eocene, miocene, pliocene—are chiefly represented in Hants and Norfolk, and parts of Lincolnshire. The marsh-lands and drifts, and post tertiary formations, have their representative examples in Lincolnshire.

The great rock and other formations which we have thus cursorily enumerated must be looked upon as having primarily contributed all the mineral constituents of the soils now spread over the country. It will be seen that the depositary rocks of ages incalculably remote appear on the surface, and those of succeeding periods of time are also exposed more or less extensively. Had these great formations remained undisturbed in their profound depths, obscured by succeeding rocks superimposed in due conformity upon them according to their several periods of accumulation, the surface configuration of this part of the world would only exhibit the last result of time in fashioning its most recent depositary formation, which would then have presented a uniform expanse of clay or sand furrowed by streamlets.

Of the causes which produced the upheaval and disruption of the lower sedimentary rocks and the general disturbance and protrusion of the superincumbent masses it is not within the scope of our present work to speak or discuss; but it is necessary we should notice the fact that such disruption has taken place, thus making available the rich stores of mineral and other matters which would otherwise have been inaccessible. Volcanic forces were also at work, and at a period subsequent to some of the great changes resulting in the elevation of the land just adverted to great eruptive masses of igneous rock and narrower outbreaks of trap rock broke through the carboniferous and secondary formation, forming ranges of no mean altitude, and in their course of upheaval dislocating the strata through which the eruptive matter was forced. Succeeding this period of disturbance another, and in relation to our subject a most important change, occurred in the subsidence of this portion of the then Continent of Europe; this was coincident with a very considerable climatic depression of temperature.

The submergence was so considerable, that all, except the hills of

greatest altitude, were submerged; and their exposed summits, so marked was the cold, bore the characteristic snow and ice caps of the arctic regions. The history of soil is so involved in these great geological events, that it would be difficult to give an intelligible explanation of their occurrence and distribution without calling to our aid the revelations of the science of geology, and although our references have been to the past, the elements which have wrought such enormous changes on the face of the earth are still in action. The waves of the sea still beat and wash opposing shores; rain and wind, frost and snow, and the rushing waters of a thousand streams, still gather and transport the lighter particles of earth, forming beds of loam or alluvium, according to the positions to which it is carried; and, last of all, great earth throes still tell us of the existence of the pent-up forces that have heretofore and may again show us how unstable is the earth crust on which we tread.

Perhaps no period in the geological history of this country was more eventful in relation to our subject than that comprised in the time of the tertiary system of geologists, the divisional periods being described as eocene, miocene, pliocene, pleistocene, and post tertiary. There exists evidence of very considerable changes of climate during these periods, each climatic change fraught with events and marked by incidents that disturbed existing surfaces, and increased the deposits of earthy matter, the advantages of which reach us even at this time.

Great changes took place in the distribution of sea and land in those periods in the world's history. At one period of time shallow seas, thronged with forms of marine life, surrounded and washed the shores of islands which were clothed with a vegetation telling of warmth and humidity. Estuaries bearing the waste of the land formed deposits, in which were mingled the relics of creatures both of sea and land. Rivers, rushing in greater volume than we find in their modern representatives, formed deposits on a proportionate scale. Lakes, marshes, forests, each gave their characteristic portions of organic and inorganic results.

Another great change in the climatic and physical conditions of this part of Europe succeeded, and it was during a period called by geologists the pleistocene that the most striking and important events took place. Whether through the divergence of warm oceanic currents, or from other unascertained causes, a climate of arctic severity replaced the general conditions that heretofore prevailed. The land now forming the British Isles was partly overwhelmed by the ice-laden waters of a northern sea, and, sinking gradually, only the ranges of hills of greatest altitude remained above the waves.

The summits of these heights were heavily weighted with accumulations of snow and ice, and their rocky structures, acted upon by these and other atmospheric causes, was disrupted and displaced, and the fragments carried by icebergs, and thus dispersed over a wide area, to be found when the sea bottom became dry land, and utilised in building our palaces.

To any objection which may be raised that we are dwelling too much on the geological aspect of the subject, we venture to say that no just or intelligible account of soils can be given without direct reference to the facts revealed to us by the science of geology. If we described the preparation of a compost heap, by saying that a base of rough stone must be hewn from the quarry, gravel and sand from their beds, limestone, clay, alluvium, borrowed from their several deposits, the whole intermixed with decayed vegetable matter, the account would be accepted as appropriate. In referring to the causes in the far-off history of the world that on a large scale prepared and deposited the same material, we are detailing information equally applicable to the subject.—PERCY T. INGRAM.

(To be continued.)

BLACKS IN POTATOES.

IN reading the interesting and important controversy in the *Journal of Horticulture* on this subject, I especially remarked that "Experimentalist" might well have added to his quartette of old and high quality varieties at least two others—viz., Fortyfold and Early Oxford, possessing as they did the nutty flavour, and were also veritable "crack their sides," or "starchy customers," and though not particularly heavy croppers, or of large size, were altogether up to date. I have a vivid recollection of when in my "prentice" days, often enjoying with a canny Scot an early supper, consisting alone of the said "murphies," "a wee peckle of salt," and a "sup of milk." Boiled with their jackets on, there was no loss of the full flavour of these delicious tubers.

The foregoing remarks, be it observed, apply to upwards of half a century ago, and just prior to the initiation of the murrain, and which latter, I well remember, when in full career so decimated the crops throughout the land (I think it was in 1847), that their place was largely substituted by other roots, such as Carrots, Parsnips, and Swedes.

Regarding the "Blacks" question, it is indeed worthy of fuller investigation, though I opine it is a most difficult one to elucidate. With respect to Up to Date enjoying a presumed immunity from the "disease," such has not been my own experience, inasmuch as among the several samples that have come under my cognisance, especially during the past season, they have been more or less affected.—W. G., Birmingham.

CYPRIPEDIUM OLENUS BURFORD VARIETY.

THIS is one of the grandest *Cypripediums* that has been exhibited. Its size and the massiveness of all the organs place it in the front rank of the hybrids that have *bellatulum* as one of the parents. *C. Olenus* was shown in March, 1895, by Mr. H. J. Chapman, gardener to R. I. Measures, Esq., but it is quite superseded by the Burford Lodge variety which was staged by Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart. The flower is shown natural size in the woodcut (fig. 71), and is therefore about 5 inches across. The dorsal sepal is of immense size, the ground colour being white, almost pure at the margins, but nearly imperceptible at the base by the deep claret markings. Shining claret is the colour of the pouch and the base of the petals, which are blush white at the tips. *C. Olenus* Burford variety resulted from a cross between *C. bellatulum* and *C. ciliolare*, and was awarded a first-class certificate by the Orchid Committee of the Royal Horticultural Society on the 12th inst.

ODONTOGLOSSUM

ROSSI MAJUS.

IT is not my intention in this short note to go into details as to the merits of this easily grown and useful cool house Orchid. They are already well known to professional and amateur alike, but in visiting an amateur recently I could not fail to notice the superiority regarding the free flowering properties of plants grown on small blocks to those grown in pots, the flowers, too, being much larger. The blocks were made of teak wood, all the material used being a little sphagnum moss, which was held in position by copper wire. To those having to economise in the matter of space this system is to be recommended, as they take up small space, are easily dipped or syringed, and most certainly show their flowers to greater advantage than when grown in pots.—R. P. R.

ODONTOGLOSSUM CORONARIUM.

THIS is a very fine species when well grown, and though variable, not one of the varieties but that is well worth growing. In habit it somewhat resembles *O. grande*, but is looser, so to speak, not so tufted, and consequently requires larger receptacles to grow it well. Good plants may be grown in large flat baskets suspended not far from the roof in the cool house, when the light reaches every part of the plant, yet it is shaded from bright sunshine. The scapes appear in late winter, and are now in full beauty.

They are upwards of a foot in length, the colour of the flowers in the type being rich deep brown on the sepals and petals, this being

marginated with yellow. The lip is deep yellow with large brown blotches, and the flower has a glossy surface, as if varnished. Peat fibre and sphagnum moss, with abundance of large rough lumps of charcoal and crocks, suit it well as compost, the large fleshy roots taking hold of this class of material better than that of a finer closer character. Drain the baskets or pots thoroughly, and keep the plants in a cool, moist atmosphere all the year round. When strong enough they will bloom, but it can hardly be described as a free-flowering species. It is a native of New Grenada, introduced in 1847.—C. H.

[CÆLOGYNE PANDURATA.

A DESCRIPTION of this plant fails quite to give an idea of its beauty, and only those who have seen well-flowered specimens know what a distinct and beautiful thing it is. In habit it is very strong, the pseudo-bulbs occurring at several inches apart on the rhizome, and having several deep green leaves 18 inches in length on the strongest plants. The bloom spike contains many flowers, and these are upwards of 3 inches across, the sepals, petals, and ground colour of the

lip bright emerald green, the latter being beautifully crested, and otherwise marked with black, a very pretty combination, as striking as any in the genus.

As noted, the pseudo-bulbs are distinct, and this naturally causes the plant to soon grow out of the ordinary pot, basket, or pan. Many growers for this reason use long trellised rafts, very lightly dressed with peat fibre and moss, the roots taking hold of this, and the plants flourishing well. Tree Fern stems, again, make a splendid holding for the roots, the natural roughness of the material suiting them exactly, and the plants have a fine appearance thereon when in bloom. The pieces of stem should be as large as possible in the first place, for when once the roots get a hold they are bad to transplant.

There is nothing worse for this class of Orchid than the huge lumps of cork, with pieces of peat wired to them, that

were at one time popular. No matter how carefully placed, they were very ugly, and not only this, but the peat was always silting out over other plants, or on the stages and paths. This, too, led to the plants getting very loose, hanging by the roots as it were, looking untidy, and doing badly. It would be far better to plant in pans, and let them grow over the side, as they would, than to grow them in this way.

But a raft, or even a flat basket, is easily made, and should be used if the Fern stems are not at command. *C. pandurata* likes plenty of moisture at the roots while growing, and the atmosphere must also be kept moist. Sprinkling should not be overdone, but is very helpful in summer in keeping the foliage fresh. At all times, when growth is at all active, the roots must never be really dry; and when growing freely, almost aquatic treatment is necessary. When resting, the supply must be shortened a little, but to allow the pseudo-bulbs to shrivel is quite wrong, leading to weak, puny flower spikes, and badly developed growth. Still, little more water than is necessary to prevent this must be given during the winter months.

FIG. 71.—CYPRIPEDIUM OLENUS BURFORD VARIETY.

In its native habitat *C. pandurata* is found growing "in the hottest jungles on the banks of streams, where during the rainy season it is impossible to collect them," so that under cultivation it is hardly possible to keep it too warm and moist, as the habitat is in Borneo. Heat and moisture, then, are the first conditions necessary, and if the atmosphere can be well supplied with ammonia by sprinkling the floors and stages with soot water, or placing dry soot and lime about under the stages, the progress of the plants will be all the better. They will soon take on that deep green, almost black, tinge in the foliage that is indicative of health and vigour.

In the kind of atmosphere induced by these means there will usually be little trouble with insect pests, for thrips and red spider, though active enough in a hot dry atmosphere, are not at all comfortable when plenty of moisture and ammonia are present. But if either of these puts in an appearance, no time must be lost in setting about its removal, for the insects soon ruin the fresh green appearance that is the greatest attraction of the species. *C. pandurata* first flowered in this country in 1853 with Messrs. Loddiges of Hackney, about a year after its discovery. It takes its name from the shape of the lip, which is almost exactly that of a violin.—H. R. R.

FAIR DEVON—ENDSLEIGH.

GARDENS of note abound in Devonshire, and numerous able practitioners at the present time, as well as in the past, have furnished conspicuous examples of what British horticultural skill can accomplish as regards all the usual produce. But there are two characters which particularly distinguish the Devonshire estates, and arrest the attention of the traveller in every district. One is, that naturally picturesque sites furnish a most delightful variety in the scenery, of which the "Art that conceals Art" has taken the fullest advantage; and the other is the abundance of freely grown trees and shrubs, especially those of the evergreen type, which are seen in nearly every park and garden. As regards Conifers, perhaps there is scarcely a county in England that could show a larger proportion of handsome specimens of the best or rarest species. The temperature, rainfall, and soil are evidently exactly adapted to their requirements, and they luxuriate accordingly, notwithstanding that some of the tenderer occasionally suffer by frost in the late spring.

For early vegetables the gardens of Devonshire, both private and commercial, have long been famed, the climatal conditions being eminently favourable to such produce. But even in such a favoured county the late frosts are sometimes most disastrous, many a promising crop being decimated. An example of the evils thus experienced in regard to bedding plants, which gardeners in more northern districts are apt to think peculiar to their own localities, is afforded by the following, in which the writer is only recording what happened to many others: "In one season, a few years ago, I completed the bedding-out on June 16th, and on the following day half the plants were killed to the ground by frost." The full meaning of this can be duly grasped by those who have the whole resources of their establishment exhausted to provide accommodation for sufficient plants to fill large flower garden designs, allowing no space for reserve forces. In many of the counties around the metropolis it is customary to regard planting-out tender bedding plants as a risky proceeding until the third week in May is passed, and in low situations it may not be safe until after that; but the second week in June would be thought late. The instance given shows how greatly a garden is dependant upon weather conditions that cannot be foreseen, and from which the most skilful are liable to suffer as well as the careless or incompetent.

The River Tamar, which constitutes the boundary between Devon and Cornwall, presents in the charming valleys of the upper portion of its course numberless picturesque sites for gardens and estates. One of the best chosen and most delightful of these is that where Endsleigh Cottage is placed, the Devon residence of the Duke of Bedford, for while Nature has liberally endowed the surroundings with her greatest attractions, art has been employed with accurate judgment, and is in consequence nowhere obtrusive. The "Cottage" itself is an unpretentious structure, quite in keeping with the scenery, and, standing on a site slightly elevated above the Tamar, it commands a pleasing view of the river windings and the tree-clad hills on each side, at the same time serving to complete the picture.

Endsleigh is about six miles from Tavistock, and constitutes one of the attractions to visitors in this part of Devonshire. By the liberality of its owner the grounds can be inspected by all who take the slight trouble needed to procure a visiting order at the estate office in the town. The journey by road, too, is one of the most varied and agreeable in the neighbourhood, an extremely pleasant trip for a summer's afternoon. The carriage drive from the entrance to the gardener's house reveals one of the great characteristics of the place—namely, the wonderful vegetative vigour of the trees and shrubs.

Rhododendrons in particular grow with extraordinary luxuriance, necessitating frequent hard cutting to keep them within bounds, and it is not an unusual occurrence after a severe pruning for the plants to make growth 3 feet in length in one season. A large part of the plantation is formed of *R. ponticum*, but a collection of the best hybrids is also included,

as well as some of the finer species of the Himalayan group. *R. Falconeri*, for instance, one of the handsomest Rhododendrons in cultivation, succeeds uncommonly well, and has even been known to escape injury when *R. ponticum* and the common Laurel have been killed by frost. This is an interesting illustration of how much the condition of individual plants influences their injury by frost and other means; there is often a greater difference in this respect between individuals of one species than between distinct but allied species.

One of the best points to which visitors should direct their steps for obtaining a general view of the charms of the Tamar valley and slopes is the "Swiss Rock," where, from a little "coign of vantage" on a precipitous height some 200 feet above the river, a unique and delightful prospect is commanded. Upon the opposite or Cornish side the hills rise to a considerable height, heavily wooded; the river is seen winding its way at the base, broken here and there by its rocky course, and in the distance the "Cottage" stands out from a background of trees and shrubs, varied both in form and height. On the occasion of my visit the afternoon of a short but brilliant autumn afternoon was drawing to a close; the sun was sinking to the Cornish hills amidst wide-spreading reflections of the richest crimson and gold, producing an effect that would have tested the skill of the greatest landscape artist to transfer to canvas.

Humphrey Repton was consulted by a former Duke of Bedford with regard to some improvements in the Endsleigh estate, and he prepared a report which contained many interesting passages. From one of these the following may be quoted:—"There are hardly two things in Nature more contrasted than a river near its source in a mountainous country and the same river when it becomes navigable and spreads itself into an estuary like the Tamar at Plymouth. Nothing can be more delightful to those who have braved the storms of the ocean than to sail between the romantic banks of the Tamar, whose echoing rocks often repeat the music which from pleasure boats enlivens its peaceful surface; and a cottage on the banks of the Tamar will naturally suggest such tranquil scenery. Very different is that of Endsleigh. Here solitude embosomed in all the sublimity of umbrageous majesty looks down on the infant river struggling through its rocky channel and hurrying onwards with all the impetuosity of ungoverned youth till it becomes useful to mankind." To the view from the "Swiss Rock," in fact, the river imparts life, character, and relief, widely different from what a lake would afford in such a scene, or a placid river like the Thames at Richmond as seen from the Terrace.

Rich plantations of trees and shrubs extend along the hillsides to the "Cottage," and beyond, a detailed list of which would occupy more space than the Editor could spare or I should be disposed to fill. But reference must be made to some of the finest specimen trees, especially among the Conifers, the majority of which are so thoroughly at home. The Firs are represented by handsome giants furnished from the ground to the apex with vigorous branches and possessing the distinguishing tints of health. For example, *Abies Albertiana* may be noted, the height being nearly 60 feet, and numerous as are good specimens of this Fir throughout the country, there are few to surpass this in symmetry and condition. At Castle Menzies in Perthshire there is a tree 72 feet high, and that is the highest known to me. *Abies concolor*, though only some 35 feet high, is an excellent specimen of this beautiful Fir, the same remarks applying to it as to the preceding; but at Linton Park, Maidstone, is a tree of the species 64 feet high which is shown to visitors with a great deal of pride.

Abies Douglasi, 80 feet in height, and 12 feet in diameter at 3 feet from the ground, is superb in all respects, and though it is surpassed by the Dropmore Douglas Fir in mere height, which is estimated at 120 feet, I do not think it is equalled in other points. *Abies grandis* is a magnificent Fir when seen like it is at Endsleigh over 50 feet high and beautifully proportioned. Of *Abies Morinda* there are several specimens about 40 feet in height, while *A. nobilis* runs up to 65 feet, *A. Nordmanniana* to 70 feet, and *A. pectinata* to 100 feet. I do not know a taller and better developed *A. Nordmanniana*, and I have only heard of two specimens of *A. pectinata* of greater size in cultivation.

The Pines are not so remarkable as the Firs, for though there are several large specimens, they have either suffered in gales or the lower branches have died away. It is thought that the south-westerly slopes are too hot for them, and that, notwithstanding the heavy rainfall, the moisture drains away from their roots too quickly. Still *Pinus Strobus*, 75 feet high, and *Pinus Laricio*, 70 feet, are fine trees; while an old example of *Pinus Montezumæ*, though only 30 feet high, is notable and interesting. The last named is a Mexican Pine, which was introduced by Hartweg in 1839, but is generally regarded as not hardy in England, though it appears safe enough in Devonshire and Cornwall. It is very common and very variable in its native country, and to the latter circumstance is due the large number of different names that have been bestowed upon it. For instance, Dr. M. T. Masters gives no less than fifty-eight synonyms. It is rather unfortunate that two supposed distinct Pines, selected to do honour to a former Duke of Bedford and a Duke of Devonshire—i.e., *Pinus Russelliana* and *P. Devoniana*, which have both proved to be identical with the protean *Pinus Montezumæ*; at least, that is the determination of the authority above mentioned, though in Veitch's "Manual of the Coniferae" it is said the specimen of *P. Russelliana* at

Bicton is distinct from *P. Montezumæ*. This unfortunately I have not seen, though I find there is an impression amongst several that they really are distinct.

Amongst other Conifers that thrive uncommonly at Endsleigh, *Cupressus Lawsoniana* is conspicuous, one example reaching nearly 70 feet, in magnificent condition, and surpasses the great majority of trees of this Cypress in British gardens; but I have seen one at Dupplin Castle, Perthshire, that is a near rival, though it is under 60 feet in height. *Cupressus nutkaensis* and *Cryptomeria japonica* are each about 45 feet high; *Wellingtonia gigantea*, 80 feet; *Araucaria imbricata*, 45 feet; *Taxodium distichum*, 50 feet; *Cedrus Libani*, 70 feet; *Sequoia sempervirens*, 45 feet, and *Thuia Lobbi*, in several good examples 40 to 60 feet high, are the most remarkable of the larger trees. It must be mentioned, however, that *Retinosporas* succeed, numbers of handsome specimens being observed near the walks.

A picturesque feature is the glen which extends from the higher part of the ground to the neighbourhood of "The Cottage," with a stream running through it, dashing at intervals over rocky falls. Being sheltered on each side by the tree plantations and shrubberies abundant suitable sites have been provided for tender plants, and those which thrive in moist situations or near running water. Full advantage has been taken of these, and quite a sub-tropical character is imparted to portions of the glen by means of Palms, the taller grasses of the *Gynerium* type, and rare or tender shrubs. *Chamærops Fortunei* and *C. humilis* have both stood out for some years, and have passed through severe frost trials unscathed. They are in good condition, and appear to find the conditions exactly suited to their requirements. That interesting shrub *Benthamia fragifera*, however, suffers frequently by frost, and consequently does not make much progress, though I have seen it thrive in much more exposed and colder positions. Situation and moisture have a great bearing on the hardiness of plants of all kinds. I imagine that at Endsleigh there is a marked difference between the climatal conditions of the higher and lower ground.

It is only in the gardens of our southern and western counties that the Tree Heath, *Erica arborea*, is seen in its full beauty; indeed, it is rarely found in cultivation here, even under glass, though the reason for this neglect would be difficult to discover, as it is equal in attractions to many other species that are in favour. In the Southern States of Europe it is often a conspicuous object, attaining the height of 12 feet or more; and as it flowers profusely, huge bushes appear to be a mass of blossom. At Endsleigh this *Erica* is evidently thoroughly at home, vigorous specimens 7 to 8 feet high having a grand effect when their branches are thickly set with the long tubular white flowers, as they are usually in the late autumn months. A sheltered situation is accorded to the plants, but they seem to escape the spring-frosts injuries, which cause trouble to so many other shrubs. The wood of this Heath has been in great demand for the manufacture of pipes, and the French word "*Bruyère*" has been converted into "*Briar*" here, which conveys a very different and erroneous impression as to the source of the material so much in request.

Much more was there to be seen and noted at Endsleigh, but the shades of an autumn evening were fast obscuring the prospect, and when the kitchen garden was reached the light only sufficed to show that it was admirably kept and stocked, just indeed as might be expected at the hands of so capable a gardener as Mr. Frank Yole.—VIATOR.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—APRIL 26TH.

THE display in the Drill Hall on Tuesday, when the Auricula and Primula Show was held in connection with the regular meeting, was very rich and diversified. Every section was well represented.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with Rev. W. Wilks, and Messrs. G. Bunyard, J. Cheal, P. Veitch, A. H. Pearson, G. W. Cummins, A. F. Barron, W. H. Divers, G. Norman, J. Willard, J. Smith, G. Wythes, J. H. Veitch, W. Pope, W. J. Empson, A. Dean, and J. Wright.

Mr. H. T. Martin, gardener to Lord Leigh, Stoneleigh Abbey, sent extremely large heads of Seakale, some of them weighing 1 lb. each. They had presumably been grown from unusually large crowns covered in the open ground. A cultural commendation was unanimously awarded.

Mr. J. Read, The Gardens, Bretby Park, Burton-on-Trent, sent samples of a late and proliferous vegetable, *Read's Sprouting Kale*. It was called Read's Sprouting Broccoli, but as plants are grown at Chiswick and approved there the variety was determined to be a Kale. It is distinct from all others, and will probably prove a serviceable addition to late spring greens (award of merit).

Mr. Owen Thomas sent from the gardens of her Majesty an extremely handsome Melon, *Lord Edward Cavendish*. Fruit large round, with a thin rind, chastely netted; thick, tender, white flesh, faintly tinged with green, juicy, and pleasantly flavoured. The best Melon that has been exhibited at any of the Society's meetings in April. An award of merit was unanimously granted.

Mr. G. Wythes, Syon House Gardens, arranged an extensive and admirable display of vegetables. It comprised upwards of thirty dishes,

all in the pink of condition for a nobleman's table. Potatoes, French Beans, Cabbages, and Broccoli in variety, Mushrooms, Seakale, Asparagus, Tomatoes, Peas, Kales, Spinach, Tomatoes, and Lettuce were all excellently represented, and a silver-gilt medal was unanimously awarded.

Of equal merit in the estimation of the Committee was a very fine assortment of fruit and vegetables from the gardens of Mrs. Wingfield, Amphill House (gardener, Mr. W. J. Empson). A row of Royal Sovereign Strawberry in pots, laden with rich scarlet fruit, made a handsome background. The central object in the group was a bunch of Bananas, flanked by large Apples and Pears. The vegetables consisted of enormous Leeks and Onions, diminutive tender Radishes, bright Tomatoes, excellent Potatoes, Asparagus, Cucumbers, and Seakale. As above indicated, a silver-gilt medal was unanimously awarded.

PRIZES FOR FLAVOUR.—The first prize for a dish of Apples went to Col. Brymer, Dorchester, with Allen's Everlasting; and the second to C. P. Serocold, Esq., with Herefordshire Pearmain. No Pears were staged.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, Owen Thomas, C. T. Drury, H. B. May, G. Nicholson, R. Dean, G. Stevens, W. Howe, J. F. McLeod, T. Peed, R. B. Lowe, J. Jennings, N. F. Barnes, J. Hudson, C. Jeffries, W. Bain, J. D. Pawle, C. E. Shea, J. W. Barr, T. W. Sanders, E. T. Cook, E. Beckett, H. J. Jones, D. B. Crane, G. Paul, H. S. Leonard, G. Gordon, and H. Turner.

The several splendidly flowered plants of *Azalea mollis* from Messrs. R. & G. Cuthbert, Southgate, made a charming display. Many named varieties of merit were observed. Mr. John Walker, Thame, sent half a dozen boxes of *Maréchal Niel* Roses, which diffused a pleasing fragrance. A small group of alpine plants came from Mr. T. S. Ware, Tottenham. There were Primulas, Saxifragas, Trilliums, and several others. Messrs. Paul & Son, Old Nurseries, Cheshunt, staged an interesting exhibit of hardy flowers in capital condition. The plants were in good health, and as a rule were flowering freely. Conspicuous among the many were *Aubrietia Froebeli*, *Gerbera Jamesoni*, *Alyssum saxatile* fl.-pl., *Geum minimum*, *Viola Skylark*, *Primula altaica*, *P. rosea*, *Doronicum plantagineum excelsum*, *Adonis vernalis*, several Saxifragas, and others.

A handsome group of *Gloxinias* was arranged by Messrs. J. Laing and Sons, Forest Hill. It was apparent that the strain is an excellent one, for not only were the colours well diversified, but the flowers were of good size and substance. The plants were very floriferous. Mr. W. J. Empson, gardener to Mrs. Wingfield, Amphill, Beds, showed a magnificently flowered plant of *Trillium grandiflorum album*, while J. H. Arkwright, Esq., sent from Leominster bunches of beautiful Primrose Evelyn Arkwright. Mr. J. Crook, gardener to W. H. Evans, Esq., Forde Abbey, Chard, exhibited flowers of *Rhododendron Veitchi lævigatum*. Messrs. J. Peed & Son, Norwood, exhibited an assortment of finely grown *Dracænas*. There were a considerable number of varieties in each case. The foliage was splendidly coloured and of great substance.

Messrs. J. Veitch & Sons, Ltd., Chelsea, staged in splendid condition *Deutzia hybrida Lemoinei*, *Rhododendron indica Kämpferi*, and *Chionanthus virginicus*. Sir John T. D. Llewellyn, Bart., Penellgare, Swansea, showed a most interesting collection of hardy Himalayan *Rhododendrons*. Almost the whole of them were named, and some of them were very handsome, the colour being rich and the flowers of great size. Messrs. R. Wallace & Co., Colchester, exhibited a small group of hardy flowers, comprising mainly *Erythroniums*, *Fritillarias*, *Tulipa Greigi*, and *Trillium erectum*. Mr. W. Fyfe, gardener to Lord Wantage, Lockinge Park, Wantage, sent a large exhibit of Fortune's Yellow Rose. The blooms were of superb quality, and represented the best of cultivation. Mr. H. B. May, Upper Edmonton, exhibited a group of gold and silver Ferns in variety. The group was of much interest.

The large exhibit of Roses from Mr. W. Rumsey, Joyning's Nurseries, Waltham Cross, was an admirable one. The varieties were numerous, the flowers of good form, and the colours rich. Amongst the most noticeable were *Maréchal Niel*, Mrs. Rumsey, Niphetos, Ernest Metz, Ulrich Brunner, Madame Hoste, and Alba Rosea. Mr. W. Mount, Canterbury, showed Roses in superb form. Catherine Mermet, The Bride, Ulrich Brunner, and several others were magnificent. The growth made by the Canterbury Roses is wonderful, as was proved by the flowers that were shown on long stems. Mr. W. Bain, gardener to Sir Trevor Lawrence, Bart., Dorking, showed a group of Anthuriums that were far above the average of merit.

Messrs. Barr & Sons, King Street, Covent Garden, were represented by a remarkable little group of Ophrys, and Primulas and Saxifragas, with single and double Tulips. Messrs. Paul & Son, Cheshunt, showed an exceedingly floriferous Polyantha Rose, named Psyche, which Mr. Paul, jun., has raised from a cross between Golden Fairy and Crimson Rambler. It should be an acquisition. A new H.P. named J. B. M. Camm also came from Cheshunt, as did one or two *Rhododendrons*. Messrs. Linden, Brussels, sent a number of Anthuriums in variety.

Rhododendron Nuttalli in grand form was shown by Mr. W. Howe, gardener to H. Tate, Esq., Streatham; while G. F. Wilson, Esq., sent Primrose of excellent quality. Messrs. Osman & Co., Commercial Street, sent dried Ferns on a groundwork to form lamp shades and other ornaments.

NARCISSUS COMMITTEE.—Present: J. T. Bennett-Poë, Esq. (in the chair); with Miss Willmott, Rev. S. E. Bourne, Messrs. W. Golding, F. W. Burbidge, Kingsmill, G. H. Engleheart, and C. Scrase Dickens, Hon. Secretary.

A large and comprehensive display of Daffodils was staged by Mr. Thos. S. Ware, Hale Farm Nurseries, comprising fine bunches of

Emperor, bicolor Victoria, bulbocodium, Sir Watkin, Horsefieldi, Cynosure, Wm. Golding, and I. sulphureus Beauty. Messrs. Barr & Sons, King Street, Covent Garden, staged an admirable collection of Narcissi. The whole assortment was remarkably fresh and bright. The chief forms were Matron, Vincent, Madame De Graaff, Mrs. Camm, Ladas, Cecilia, Weardale Perfection, Apricot, Mrs. H. Barton, Mrs. C. Bowley, Glory of Leyden, Gloria Mundi, Shakespeare, I. Beauty, and Queen of Spain.

Messrs. J. R. Pearson & Sons, Chilwell Nurseries, Notts, also enriched the display of Narcissi, contributing a number of very handsome bunches. The chief were Emperor, Sulphur Phoenix, Leedsi amabilis, maximus, Minnie Hume, Lulworth, Mrs. Langtry, Glory of Leyden, Jas. Walker, and Figaro. Messrs. Jas. Veitch & Sons, Chelsea, produced a very choice display of Narcissi, tastefully arranged with small Maiden-hair Ferns. The best were Leedsi Gem, La Grandesse, Hon. Mrs. Barton, Duchess of Westminster, poeticus poetarum, Sulphur Phoenix, C. J. Backhouse, and Mrs. J. B. M. Camm. The Rev. G. H. Engleheart, Appleshaw, Andover, staged a choice collection of hybrid and seedling Narcissi. The most striking were Will Scarlet, White Lady, Longfellow, Garnet, and others.

ORCHID COMMITTEE.—Present: W. Thompson Esq. (in the chair); with Messrs. J. O'Brien, de B. Crawshay, H. Ballantine, H. Little, A. H. Smee, F. J. Thorne, H. J. Chapman, W. H. White, W. H. Young, E. Ashworth, T. W. Bond, W. Cobb, H. Williams, J. Douglas, H. M. Pollett, E. Hill, S. Courtauld, and T. B. Haywood.

Messrs. H. Low & Co. Enfield, were represented by a bright collection of Orchids; Dendrobiums, Cattleyas, Odontoglossums, and Cypripediums made up the bulk of the display. A few Odontoglossums came from J. Bradshaw, Esq., Southgate; while the Right Hon. J. Chamberlain sent from Birmingham a small group containing Lælio-Cattleyas, Epi-Cattleya guatemalensis, Galeandra Devoniana, and others. Messrs. J. Veitch & Sons showed a charming group of Orchids. The plants were few in numbers, but the quality was excellent. Amongst others were noted Lælia Latona, Lælio-Cattleya Ascania, Cattleya Mendeli, Dendrobium Boxalli, D. cheltenhamense, Cattleya Philo, Epidendrum Wallisi, Masdevallia Veitchiana, and Brassia brachiata.

Smaller exhibits of Orchids came from Baron Schröder, W. Cobb, Esq., Mr. N. F. Barnes, Eaton; C. L. N. Ingram, Esq., W. Thompson, Esq., E. Ashworth, Esq., De Barri Crawshay, Esq., and others. Messrs. Linden, Brussels, exhibited a splendid collection of Odontoglossums, comprising many well known and several rare varieties. There were forms of Pescatorei, crispum, vexillarium, and several others. Messrs. B. S. Williams & Son, Upper Holloway, sent miscellaneous Orchids and foliage plants, Odontoglossums and Cattleyas forming the major portion of the group.

MEDALS.—Floral Committee: Silver-gilt Banksian to Mr. G. Mount; silver Flora to Messrs. H. B. May, J. Laing & Sons, and W. Bain; silver Banksian to Messrs. W. Rumsey, R. & G. Cuthbert, L. Linden, and Osman & Co.; bronze Banksian to Mr. W. Fyfe. Narcissus Committee: Silver Flora to Messrs. J. Veitch & Sons and Barr & Sons; silver Banksian to the Rev. G. H. Engleheart. Orchid Committee: Silver-gilt Flora to Mr. L. Linden; silver Banksian to Messrs. J. Veitch & Sons, H. Low & Co., and B. S. Williams & Son.

CERTIFICATES AND AWARDS OF MERIT.

Calla Rhodesia (J. Jennings).—The spathe of this is rich yellow and of exceptional size. The foliage is pale green with white spots (award of merit).

Cattleya Mendeli Beatrice Ashworth (H. Holbrook).—Save for suffusions of blush this is a pure white form with a yellow throat (award of merit).

Cattleya Schröderæ amabilis (J. Veitch & Sons).—A grand form. The prevailing colour is soft rose, the throat being orange buff (award of merit).

Cattleya Sedeni (T. W. Bond).—A hybrid resulting from a cross between C. Lawrenceana and C. Percivaliana. The sepals and petals are rich deep purple-rose, as are the fimbriations of the lip. The central patch is bright crimson (award of merit).

Cattleya Schröderæ, Harefield Hall var. (E. H. Hobbrough).—A superb form of the well known type (award of merit).

Cymbidium, no name (J. Sparks).—The sepals and petals of this Orchid are almost black, and the small lip dull crimson (award of merit).

Deutzia parviflora (J. Veitch & Sons).—A handsome Deutzia with heads of pure white flowers (award of merit).

Lælio-Cattleya Thorntonii (J. Veitch & Sons).—Resulting from a cross between Lælia Digbyana and Cattleya Gaskelliana, this is very handsome. The sepals and petals are soft rose suffused with purple. The lip partakes largely of the character of L. Digbyana. The central colour is yellow paling to white, and the fringe is pink. The petals are serrated (first-class certificate).

Lælio-Cattleya Wellsiana langleyensis (J. Veitch & Sons).—Another bigeneric hybrid. The parents were Lælia purpurata and Cattleya Trianae. The broad petals are rose flushed with purple, and the petals pale blush. The handsome lip is velvety purplish maroon, deepening towards the throat, which is yellow with rose at the base (first-class certificate).

Narcissus Diadem (G. H. Engleheart).—Of this variety the crown is shallow and very broad, with a rose edge over the yellow ground. The perianth segments are cream (award of merit).

Narcissus Will Scarlett (G. H. Engleheart).—A superb variety. The

magnificent cup, rich orange in colour, is fully an inch across. The perianth segments are white (first-class certificate).

Narcissus White Lady (G. H. Engleheart).—A good form of incomparabilis. The crown is pale yellow, and the perianth segments white (award of merit).

Narcissus Ivanhoe (J. Veitch & Sons).—An incomparabilis of undoubted merit. The perianth segments are pure white, and the crown very rich orange (award of merit).

Odontoglossum Hunewellianum (H. Greenwood).—The yellow ground colour of this flower is almost hidden by the chocolate markings (award of merit).

Odontoglossum Pescatorei Duchess of Westminster (N. F. Barnes).—A lovely Orchid. The maroon spots are large and abundant on the pure white ground (award of merit).

Primrose Evelyn Arkwright (J. H. Arkwright).—An exceptionally fine form of the common Primrose (award of merit).

Pteris Summarsi (H. B. May).—This is a handsome crested Pteris of dwarf compact habit (award of merit).

Rose Psyche (Paul & Son).—A Polyantha Rose of much promise. The flowers are large and of a rich pink colour (award of merit).

Rose, The Dawson (Paul & Son).—A semi-double Polyantha Rose of good habit. The colour is bright rose (award of merit).

INDIAN AZALEAS IN USEFUL COMPANY.

THE contribution on Indian Azaleas on page 232, to which I volunteered a supplement on page 278, also referred to the claim these lovely flowers have on a house to themselves, which I consider perfectly justified. It might, however, occur to amateurs to join other appropriate plants to such a collection as will do well under similar treatment. Such I now suggest, but before naming them I should like to acknowledge an omission from my former list of Azaleas of an old favourite, Madame V. de Cruyssen, of very lively light crimson colour, also two more of lustrous metallic tint—Baron de St. Genois, very double, flowering in June; and a newer variety, Prince Rudolph, both acquisitions.

To produce the desired abundance of flowers on Azaleas annually it may be a service to some of the younger growers trying for a display to know that after flowering, and the removal of seed pods, they should be kept in a genial atmosphere for a month in order to promote growth, and be freely syringed. After this they may be turned out of doors in June, July (in the south), but not exposed to the full sunshine before the middle of August, and be re-housed a week or two before frosty nights occur in September. A fair number of the plants named in the following lines will succeed under similar outdoor treatment.

HIMALAYAN RHODODENDRONS.—These require syringing even more freely than Azaleas, both indoors and out, in dry summer weather. They are the most appropriate companions of the Indian Azaleas. Among them is a conspicuous beauty, Veitchianum, white, with undulated edges; Edgworthi, fragrantissimum, white, without undulations; Countess of Haddington, Falconeri, Countess of Derby, jasminiflorum, carminatum, formosum, ciliatum, the two latter smaller than the others. If grown in standard form 3 to 4 feet high, and kept well regulated in short growths, the weight of their abundant flowers will on expansion depress on some varieties the lower branches so as to meet at the stem and form a perfect globe. I have seen Edgworthi thus treated with 250 flowers open simultaneously, an object of unsurpassed beauty, its scent being not the least of its desirable attributes.

Amongst other hardwooded plants for association are the following:—

ACACIAS.—A large and elegant family of greenhouse plants, varying in colour from lemon to yellow, such as Drummondii, dealbata, grandis, armata, and Riceana, all of them attractive, while others possess distinct features in foliage or habit.

BORONIA.—One of the choicest flowering greenhouse plants is B. heterophylla, with its profusion of rosy magenta pendant bells (see woodcut, fig. 72). B. Drummondii has smaller flowers, and is more fragile; while B. pinnata and B. serrulata are clear rose, and differ in habit from the former. B. megastigma is of quite another character, the small flowers being dark brown and delightfully fragrant.

ERICAS AND EPACRIS.—The former from the Cape Colony, such as the ventricosa varieties, Cavendishiana, and many others. The Australian Epacris are similarly decorative, E. miniata splendens being extremely bright, and hyacinthiflora candidissima the finest white.

There are numerous other hardwooded plants, which, though less popular than they were a generation ago, are still well worthy of cultivation. Some of these I may, perhaps, refer to on a future occasion.—H. H. R.

ALEXANDRA PALACE.—It is many years since a flower show was held within the precincts of the Alexandra Palace, but now on its re-opening we find flowers are to form one of the attractions. We have before us the schedule of an exhibition that is announced for May 18th, 19th, and 20th, just one week prior to the Temple Show of the R.H.S. Only fourteen classes are particularised, of which a dozen are open to all, nurserymen being excluded from the remaining two. The sum of £16 is offered in three prizes for a group of miscellaneous plants on a central ground of 250 feet, and £9 10s. for another group of about half the size, not open to nurserymen. Other classes are for Orchids, specimen plants, Calceolarias, tuberous-rooted Begonias, and cut flowers. Applications for particulars and schedules should be made to Mr. R. Dean, Ranelagh Road, Ealing, who is the Show Secretary and Superintendent.

PLANTING VINES.

THIS is a good time for planting young canes, as they now start naturally into growth, almost always making some leaves before pushing roots. In well-drained soils, such as calcareous loams over gravel or other natural drainage, expensive borders are often worse than the ordinary staple, and though I prefer planting the Vines inside, there is no question of outside borders giving the least trouble in respect of watering. Besides, I am not convinced of the inside border system being the best for Vines required to start in March, and perfect their crops in August and September; indeed, the outside border, under the conditions quoted, has decidedly the advantage in respect of the best possible supplies of water, not any being equal in nutritive value to that from the clouds. But the great objection to outside borders, in many places, is the bare appearance and consequent eyesore in the estimation of the proprietor or visitors. Even many growers strive to utilise the border for certain things that require a sheltered situation or a rich soil to arrive at an early or extra degree of perfection. Laudable as this may be in intention, it often means a sorry appearance in Grapes.

For greenhouses the outside border means a great deal to the proprietors—all the space inside available for plants, and no danger of ruining the Vines by too much water in their resting season. But the outside border must be kept wholly and solely for the Vines, and I may mention that a certain proprietor had to cover his Vine border with flints from the chalk formation in order to keep the gardener from planting it with prize Asters. In the whole course of my long experience I never saw such a transformation in growing Grapes as was effected by the flints. The Vines, lank in growth, loose in bunch, red and shanked in berry, produced in two years after the stone, or rather pebble mulching, stout wood, leathery leaves, compact clusters, purple-black berries, and not any shanked. It was merely a change from prizetaking with Asters to "first" for Grapes. The flints had a sort of rockwork-like appearance in summer, for in winter the border was mulched with short stable manure, and in March it was cleared off and the stones raised and again placed on the surface. The rain soon washed them clean, and they got quite hot on sunny days, and on raising them the Vine roots were revealed quite white and active. Light top-dressings could be given, watering or liquid manure applied without difficulty, and the appearance was pleasing rather than otherwise.

For general purposes the borders may be partly within and partly outside, planting the Vines inside the house; but for early forcing and for Muscats the borders are unquestionably best wholly inside. If the

substratum be gravel or other porous material, a good dressing of fresh horse droppings, a couple of pounds of quarter-inch bones (with the dust in), half a pound of a mixture of air-slaked chalk lime and soot in equal parts by measure, and half a pound of double sulphate of potash and magnesia per square yard may be put on and the ground trenched, or rather stirred, as in turning a compost heap, mixing as evenly as possible. This gives the best results I have seen in Grapes, the top soil being naturally a gravelly loam, with a substratum of calcareous gravel with iron.

If the soil by nature be of an unfavourable character, it may be necessary to make an excavation, but in such case it is better to keep the

border well up. In the case of a wet subsoil the bottom may be concreted, or bricks laid on flat and run with cement, providing drains with proper fall and outlet to carry off superfluous water, the bottom inclining to them. Rubble a foot thick should be placed on the concrete, 9 inches of clear rubble and 3 inches thickness of old mortar rubbish; 24 to 30 inches depth of border is ample. Turf 2½ inches thick, taken off old or new red sandstone or limestone, a good friable loam, broken up roughly and mixed with a sixth part of old mortar rubbish, a twelfth of wood ashes or charred refuse, and a forty-eighth of half-inch bones (with the fine left in) forms a suitable compost. It should be put together rather compactly, and there is no need to make a wide border; one 4 to 6 feet wide will be sufficient to commence with.

The Vines, cut back in winter and kept in a cool house, or even outdoors with the pots protected, now have the buds moving. Turn them out of the pots, remove every particle of old soil, even washing if need be, carefully preserving the fibres. Spread the roots out straight and flat, the soil of the border having been brought to the required height or level, covering to a depth of 3 or 4 inches, working the soil well amongst them with the hand. Give a good supply of water with the

FIG. 72.—BORONIA HETEROPHYLLA.

"chill" taken off, and mulch with about an inch thickness of sweetened horse droppings. If the canes have not been shortened do not cut them now, but remove the buds from the upper portion down to where fresh growths are desired to issue, and cut away the disbudded part when the Vines have made some leaves, as there is then no danger of bleeding, nor will any take place from rubbing off the buds after they start into growth. If, however, the buds are extracted with a knife, and the wood laid bare, bleeding ensues, greatly weakening the Vines.

When the canes are planted in an outside border the exposed part must be carefully wrapped in haybands or hair felting, as frosts are not over, and the sap getting frozen may injure if not kill the Vines. Besides, the exposure to sun does them no good, but often much harm; indeed, the part outside the house should always be properly protected

from the cold of winter and the heat of summer. The aperture in the wall or other material must be considerably larger than the cane, even the rod having room for allowing some stopping material all round, so as to allow of unrestricted swelling.

In a greenhouse the Vines will come forward with the advancing temperature, they not being given any extra inducement to growth beyond sprinkling occasionally. Where the Vines are the chief or sole consideration the canes may be sprinkled twice a day, but avoid a close and forcing atmosphere. A temperature of 55° at night, 65° by day artificially, and 70° to 75° from sun heat, will bring the Vines on fast enough. If the weather be bright and the panes of glass large, shade from 10 A.M. to 2 P.M., when the house should be closed, damping the floor, border, &c. If the temperature rise to 85° or more it will be an advantage. When the Vines have started into growth give every encouragement, increasing the temperature to 60° to 65° at night, 70° to 75° by day, and 80° to 85° from sun heat. Admit a little air at 70°, as there is nothing like well-developed and thick leathery leaves for assimilating matter, and the stouter foundation a Vine has laid the better will be its health in after years, other conditions being favourable.—PRACTITIONER.

BALDRY'S SCARLET DEFIANCE RHUBARB.

As it is still true that the proof of the pudding is in the eating, perhaps the Editor will kindly give his opinion (after trial) of the sample of Rhubarb sent herewith. Several years ago the Committee of the R.H.S. invited specimens of the different varieties to be shown before them in a cooked state. We forget how many varieties were exhibited, but well remember the Committee were unanimous in awarding first honours to Baldry's Scarlet Defiance. We have grown many sorts, but find none anything at all equal to the above named variety. Is it grown under some other name, as it seems impossible that such an excellent Rhubarb can be so little known? Among all the nurserymen's catalogues received it is not named in one of them.—N. N.

[We suspect this superior variety of Rhubarb is somewhat scarce. It is, without doubt, the best in colour and quality we have proved this year. In some soils it does not seem to flourish, but judging by the stalks sent, the variety appears to be as happy with our correspondent as he is happy in its possession. In 1891 we published a description of the varieties grown at Chiswick. Baldry's Defiance is not included among them. Four varieties were cooked for comparison—Early Red, Paragon, Hawke's Champagne, and a small scarlet Rhubarb from a Lincolnshire rector. Of the Chiswick varieties, Hawkes' was the best; but for colour and sweetness far outdistanced by the Rector's. The samples from "N. N." resemble this, but the stalks are larger. We do not think Baldry's Defiance is offered under another name in catalogues generally. The Lincolnshire Rhubarb above mentioned declined to flourish at Chiswick. If this double "N." could send a few stalks to a single "N."—Mr. N. Pownall—perhaps he might favour with another disquisition on Rhubarbs. He studies them as closely, tests them as carefully, and writes on them as lovingly and agreeably as any gardener we know.]

HAVERING PARK.

THIS charming residence is owned by Mrs. C. McIntosh. The lodge gates of the principal entrance open into the delightful village of Havering, on the green of which are to be seen in good preservation the old-fashioned stocks, some of the men still employed on the estate well remembering them being in use. Close by a remarkable old Elm, which I have often seen quoted by cyclists and others, arrests attention, and though every care is taken to preserve it, it is fast going to decay. The distance of Havering Park from London is only twelve miles, whilst it is five from Romford. The extensive park is naturally finely undulated and well wooded, and is the home of the splendid herd of Jerseys for which Mrs. McIntosh is famous, her name appearing very prominently at most of the leading shows. The absence of water prevents the completion of the picture, but one or other of the valleys would lend itself admirably for an artificial stream or lake.

The mansion is an extensive structure, which was largely added to by the late Mr. McIntosh twenty-seven years ago. On the terrace from the south side a fine view presents itself, as on a clear day the boats may be seen passing to and fro on the Thames. On the north side is a commanding view of Epping Forest and Shooters Hill. The pleasure grounds are noted for a fine collection of American and other choice flowering shrubs, effectively grouped and in splendid health. There are large beds of Rhododendrons, Kalmias, Andromedas, and Azaleas, which a little later on will have a charming effect. Conifers have been largely planted, and many of them are doing well, but in some instances a judicious thinning would prevent many fine specimens from becoming crippled and spoiled. Wellingtonias by the hundred were observed, and several are grand specimens. Leading from the pleasure grounds in all directions are winding woodland walks which have been cleverly treated, and the margins planted with suitable bulbs and plants. Here and there on the outskirts are bold masses of Gorse, Broom, Berberis aquifolia, and others, while fine specimens of the Silver Birch are noticeable for their splendid clear stems.

The kitchen garden is not extensive, but it is in excellent condition. Wall and other fruit trees are well grown and give promise of good returns. Cordon Pears were particularly conspicuous. The houses are extensive, and are well cared for. Adjoining the mansion is a well

built conservatory, which contained some splendid Palms, Kentias being very fine. Clivias and all kinds of forced plants were in highly creditable form.

Vines are largely and well grown. The earliest house is chiefly planted with Hamburgs, which are in the best of health, carrying a heavy crop of shapely bunches. The Muscat house has been this season completely renovated, the old border taken out and the drainage thoroughly attended to. Half the house is planted with young canes, the other half being left, the whole of which are breaking strong and evenly. Two other houses are devoted to Grapes, one being planted with Alicantes, and the other with Hamburgs. The fruit in the early Peach house is swelling well, and the trees are heavily laden. A long range is devoted to late Peach and Nectarine culture, all the trees being very promising. About 700 Strawberries are forced in pots. The principal varieties grown are Royal Sovereign and La Grosse Sucrée, which, in various stages, are in excellent condition.

Two houses are devoted to Rose culture, and there is a wealth of fine flowers. The stove, greenhouse, Orchid, Cucumber and Melon houses are well managed. Pits and frames are stocked with Chrysanthemums, of which the large collection was in fine condition. The able gardener, Mr. King, scored well at the Aquarium last season, also carried all before him at Romford, and judging from the plants in their present stage he means business next season. All the departments of this well-kept garden reflect the greatest credit on the gardener. My visit was brought to a close after inspecting the model farm, the clean and comfortable home of the Jerseys, and the care with which they are tended is in keeping with the rest of this fine estate.—E. B.

EXPERIMENTS WITH TOMATOES.

IN your notice of my paper on the above subject published in the Journal of the R.H.S., you direct attention to a statement in reference to the value of potassic manures for Tomatoes. My intention was to state that potash was of little or no use for Tomatoes unless applied along with nitrogen and phosphates. Originally the sentence read, "Potassic manure is of little or no use for Tomatoes applied alone," but as nitrate of potash is considered a nitrogenous manure, and it was one of those that did not produce a good result, the word "alone" was erased in order to prevent any misunderstanding about the character of the manures.

In my report of the 1896 experiments it is definitely stated that when muriate of potash was applied by itself it proved to be a failure. The succeeding experiments were carried out with a view to proving whether potash manures applied separately and alone were beneficial to the growth of Tomatoes, and I may say that the results so far have conclusively proved to us that potassic manures without the addition of nitrogen and phosphates are simply valueless.—W. NEILD, *Cheshire Agricultural and Horticultural School*.

[Quite so; and the principle applies to other crops beside Tomatoes. Apart from the probability of the "heavy adhesive soil from a pasture field" containing potash, a few remarks of Mr. Cousins in his primer on the "Chemistry of the Garden" are apposite: "The 'Golden Tripod' is the name given to the presence of the three plant foods—potash, phosphate, and nitrate. If any one of these three substances be wanting no excess of the other two will make good the deficiency. Remove a leg from the tripod and over it falls. Planted firmly on its three legs, a slender tripod is capable of supporting a great weight." Nitrate of potash contains potash, and so does liquid manure from stables, and because of that, in combination of other essentials, the Tomatoes were benefited. Mr. Neild has done good service in making the experiments and publishing the results.]

SPRING SHOWS.

NEWCASTLE.—APRIL 20TH AND 21ST.

THE Durham, Northumberland, and Newcastle Incorporated Botanical and Horticultural Society has had a somewhat chequered history. Fixtures in the past have been almost invariably accompanied by wet weather and consequent failure when the shows have been held under canvas. Indeed, the disasters have been so numerous that, but for the energy of the Committee and the readiness with which outside aid has been accorded, this Society—the oldest of its kind in England—must have collapsed long since. However, for the spring display at least, there seems to be a brighter prospect. It has hitherto been held in the Town Hall and Corn Exchange, but the former is now in the hands of the decorators, so Olympia has been taken, and the show was opened on Wednesday. The change of site is, says the "Newcastle Daily Leader," in every way an advantage, for Olympia lends itself better to an exhibition of this kind, and then there is the advantage of having the whole of the plants and flowers staged in one building.

The arrangement in the present case was admirable in every way. The "groups" fronted the platform at the top. Running down the centre was a table with magnificent epergnes, hand and bridal bouquets, baskets of flowers, and sprays; flanking these on each side were others with cut flowers and plants; and round the sides were the miscellaneous decorative exhibits. The bottom of the hall was occupied by a row of superb Azaleas loaded with red and white blossom, and behind these, under the balcony, was a splendid collection of giant Palms, sent by Mrs. Jennings of Newcastle. Experts agreed that in every respect the show was the

best that has been seen in Newcastle for many years. Amongst the great centres of attraction were, of course, the bouquets, baskets of flowers, and epergnes. Altogether better quality of flowers were used this year, there was more diffusion of colour, and much more taste seemed to have been displayed in the general arrangement. Many choice Orchids were used in the floral decorations. The sprays were also very fine. The general excellence of the bouquets was so high that the Judges had considerable difficulty in giving their awards. The same may be said of the baskets.

There were about 500 Hyacinths staged, and many recently introduced varieties were to be found amongst them. Several stands of Roses were shown in good colour and bloom, and the show of Auriculas was also one that claims attention. The increased encouragement given by the Society for the cultivation of these flowers is having its effect. The collection was exceptionally fine considering the season. The groups of flowers and plants were excellent both in arrangement and quality, the extra inducements offered to amateurs having had a beneficial effect. Too much praise cannot be bestowed upon the exertions put forward by exhibitors in this department. In Azaleas, Cinerarias, Primulas, and bulbs of various kinds, the quality was far ahead of anything previously seen here.

There were many stands "not for competition," and many novelties. Most striking was a cluster of blue Primroses sent by Mr. James Douglas, Bookham. Messrs. Wm. Clibran & Son, Altrincham and Manchester, showed a general assortment of stove and exotic plants containing over forty novelties rarely met with. There were yellow Callas, Boronias, and many others. The firm also makes a speciality of Carnations, and among the many choice blooms on exhibition was a new one called Yellow Wonder, an enormous bloom of rich colour and delicate perfume. Messrs. Pearson, Notts, staged Daffodils in grand form. They had all the newest varieties on exhibition, including Madame de Graaf. It is a superb bloom, but the price is at present rather prohibitive. All other sorts were exhibited, from the large, rich yellow Glory of Leyden to the miniature mountain species Angel's Tears, and a special feature was made of the red cup varieties. Messrs. Fell & Co., Hexham, also had a good show of plants of various kinds. Other exhibits included Messrs. Emley & Sons, Newcastle, horticultural implements of various kinds; Mr. H. H. Hilliar, Darlington, plants; Messrs. W. Edwards & Son, Sherwood, Notts, table decorations; Messrs. J. Thomson & Son, Forest Hall, plants; Messrs. T. A. Hutchinson & Co., Forest Hall, plants; Mr. J. G. McKenzie, Heddon-on-the-Wall, Orchids; Mr. W. Lawrenson, Yarm, plants; and Mr. A. E. Campbell, Gourock, N.B., plants. The show was well patronised during the day. The Blue Hungarian Band, which had been specially engaged, gave concerts of high-class music during the afternoon and evening, and the programmes were greatly enjoyed. We give the names of the prizewinners in a few of the open classes.

In the open section there were several splendid exhibits from various growers of repute. For a group of miscellaneous plants arranged for effect in a space of 60 square feet, Mr. G. MacDougall was first, Mr. J. McIntyre second, and Mr. H. Hilliar third. The successful exhibitors of three specimen flowering plants were Messrs. J. McIntyre, T. Wheeler, and H. Hilliar, in the order in which their names are given. For three Orchids Mr. T. Wheeler went to the front, followed by Mr. W. Lawrence and Mr. J. McIntyre. The last named was successful with four Dielytras; Mr. W. Pitt was second, while for four Deutzias the best were staged by Messrs. W. Pitt, T. Wheeler, and H. Hilliar. Mr. J. McIntyre sent the best Spiræas, and Mr. W. Pitt the best Cinerarias. Primulas and Cyclamens were well staged by Messrs. G. MacDougall and T. Wheeler, and Lily of the Valley by Mr. W. R. Armstrong. As has been said, Auriculas were well shown. The principal prizewinners including Messrs. T. E. Hay, R. Willis, S. Bewick, G. Lee, J. Ellison, J. Cawthorne, and J. Gardener.

Very bright and interesting were the many bulbous plants in pots. There were classes for Hyacinths, Tulips, and Daffodils, and each contained specimens of excellent quality. The use of moss for covering the surface of the soil was prohibited. In the Hyacinth classes the successful staggers were Messrs. G. MacDougall, D. Wylam, T. Wheeler, A. E. Campbell, H. Dewar & Co., and W. Lawrenson. For Tulips, the prizes went to Messrs. G. MacDougall, D. Wylam, T. Wheeler, and E. Callaghan; while, practically, the same names were on the cards in the Daffodil classes. Mr. G. MacDougall was the premier exhibitor of both Gloire de Dijon and Marechal Niel Roses, and Mr. M. Wheatley of Show and Fancy Pansies.

Table decorations, bouquets, sprays, and buttonholes were beautifully arranged. For a vase or epergne for the drawing-room Mr. T. Battensby was first, Miss Edmondson second, and Mr. A. Lawless third. For a basket of cut flowers Messrs. Perkins & Son were first, Mr. F. Edmondson second, and Mr. W. Lawrenson third. Messrs. Perkins & Sons were also successful in the classes for bridal bouquets, hand bouquets, sprays for ladies, and buttonhole bouquets.

AURICULA AND PRIMULA.—APRIL 26TH.

THE Auricula and Primula Society (Southern Section) held its annual exhibition at the Drill Hall, Westminster, on Tuesday, April 26th. The exhibition has undoubtedly grown in magnitude and excellence. The majority of the classes were well filled, and in many instances the competition was very keen. The Alpine classes appear to be very popular, while the other sections were satisfactory. Great interest was manifest in the Primula species, which were well represented.

In the class for twelve Auriculas, dissimilar, Mr. J. Douglas, Great Bookham, Surrey, secured premier honours with a very even exhibit. The varieties were Olympus, grand; Mrs. Henwood, George Lightbody,

Marmion, Dr. Hardy, Acme, George Rudd, Black Bess, Mrs. Potts, Mrs. Dodwell, Negro, and Greenfinch. Mr. C. Phillips, Bracknell, secured the second place with good plants of Mrs. Dranfield, Marmion, Heatherbell, Miss Barnett, and Mrs. Phillips. Mr. Wm. Smith, Bishops Stortford, third; and Mr. J. T. Bennett-Poë, Ashley Place, S.W. fourth.

Mr. Chas. Phillips was clearly ahead in the class for six varieties, dissimilar, with good plants of Geo. Rudd, Mrs. Phillips, Mrs. Barnett, Mrs. Harwood, Rich. Headley, and John Simonite. Mr. W. Smith proved a good second with excellent blooms of Black Bess, George Rudd, and Conservative. Mr. J. T. Bennett-Poë third with very good plants of Black Bess, Acme, and Rachel.

Mr. J. Sargent, Cobham, proved the victor in a class for four varieties, in a very keen competition, staging good plants of Mrs. Potts, Abbé Listz (the premier Auricula in the show), Mrs. Dodwell, and Lancashire Hero. Mr. A. S. Hampton, Reading, second with good examples of Heroine, George Rudd, and the Rev. F. D. Horner. Mr. A. R. Brown, Birmingham, third with a good Ajax. Mr. A. Fisk, Broxbourne, fourth; Mr. Palmer, Shortlands, fifth; and Rev. L. R. Flood, Merrow, sixth.

Mr. P. Hennell, Winchmore Hill, was first for two, dissimilar, with well-developed plants of Rev. F. D. Horner and Acme. Mr. J. Sargent must have been a very near second with a capital plant of John Simonite, the other variety being the popular Abbé Listz. Mr. A. R. Brown was placed third with a good plant of Heatherbell, and a weak specimen of Black Bess. Mr. A. S. Hampton fourth, Mr. W. W. Palmer fifth, and the Rev. L. R. Flood sixth.

A good competition was brought out in the class for a single specimen, green edged, Mr. Phillips being placed first with Mrs. Henwood, Mr. Sargent second with a good specimen of Rev. F. D. Horner, and Mr. J. Douglas third with the same variety. Mr. Sargent was awarded first place for a grey-edged variety, with a good plant of Lancashire Hero. Mr. W. Smith second with Geo. Rudd, and third with Rachel.

The single specimen plants in the white-edged varieties were excellent, Mr. Sargent leading with the charming Heatherbell. Mr. J. Gilbert second with a very good Acme, Mr. Jas. Douglas third with the same variety. The single self class proved a very popular one, and brought out a numerous entry. Mr. Fisk was first with Heroine, Mr. Jas. Douglas second with Mrs. Potts, and Mr. W. Smith third with the same variety.

There were three competitors for fifty Auriculas, and the premier honour was awarded to Mr. J. Douglas for a really good exhibit. The most notable varieties were Ruby, Ajax, Monarch, Lord of Lorne, Heroine, Ariel, Venus, and Mrs. Dodwell. The Guildford Hardy Plant Nursery, Guildford, was placed second with a very even collection. Phyllis, Mrs. A. Potts, Chas. J. Perry, Brunette, Ariel, and Potts' Green were very good. Mr. Chas. Phillips third.

The Alpine classes were well filled throughout. In the class for twelve plants Mr. C. Phillips was placed first with a grand exhibit. The plants were excellent and the varieties distinct and varied. The best forms were Mrs. Martin Smith, Gladys, Lady C. Walsh, Evelyn Phillips, Vandyke (grand), and Perfection. Mr. Jas. Douglas was second, Britannia, Urania, Firefly, Dean Hole, and Lord Dudley being especially good.

A good competition was displayed in the class for six varieties, Mr. F. Whitbourne, Great Gearies, Ilford (gardener, Mr. J. W. Euston) first with Urania, good; Calypso, The Bride, and Psyche, all excellent varieties. Mr. C. Phillips second with larger plants, though they lacked the finish of the first six. Mr. J. Douglas third. For four Alpines Mr. J. W. Euston proved the winner. Mr. J. Walker was second, and Mr. A. R. Brown was third.

Mr. C. Phillips was placed first for a single plant, gold centre, with Clara, Mr. J. T. Bennett-Poë second with Dean Hole, Mr. Gilbert third with the same variety. Mr. C. Phillips was again successful in the class for a single specimen with a white or cream centre with Perfection; Mr. Keen second with Amazon, Mr. Douglas third with Edith. The Guildford Hardy Plant Nursery was well ahead in the class for twelve Fancy varieties. The best were Full Moon, Moonlight, Old Gold, Buttercup, and Belle. Mr. J. Douglas, Bookham, second with good specimens of Golden Plover, Golden Oriole, good; and Actè.

Mr. J. Douglas outdistanced all competitors for twelve Polyanthus, exhibiting fine fresh plants, comprising a very wide range of colours; Mr. G. Dixon, Chelford, second with an excellent box; and Mr. J. W. Euston third. Mr. J. Douglas was the only competitor for single Primroses, and was deservedly awarded the first prize; the plants were large and the flowers well developed. The double Primroses were quite a feature. Messrs. Paul & Son, Cheshunt, were placed first with fine pans of well developed plants. The Guildford Hardy Plant Nursery was second.

A very interesting collection was staged in the competition for twelve distinct species. Mr. Douglas first with good specimens of P. intermedia, P. pubescens, and P. floribunda. In the class for six species, Mr. J. W. Euston was placed first for good plants of P. floribunda, P. obconica, P. verticillata, and P. intermedia. The Guildford Hardy Plant Nursery was second with a very pretty basket. Messrs. Paul and Son third. Mr. J. T. Bennett-Poë was well ahead for a basket of Primroses arranged for effect. Mr. J. Douglas was second with an excellent arrangement, and Messrs. Paul & Son third.

Mr. C. Phillips was awarded first prize for a seedling self, Mrs. Dranfield. Mr. Barefoot, Croydon, was also awarded first honours for a seedling, with gold centre, named Mrs. Barefoot. Mr. Phillips second with Miranda. The Guildford Hardy Plant Nursery was first for a group of Primulas or Auriculas artistically arranged. Mr. Purnell-Purnell, Streatham Hill, was awarded second with a capital basket, and Mr. Douglas third.

BLACKTHORN WINTER.

How rarely now do we escape this above-named spring visitation! Yet is it for us as gardeners a time of the greatest interest and concern. Plums, Pears, and Cherries in full bloom, Gooseberries and Currants fully open and leafy, yet tender; and upon the safe passing through by these fruits at this critical stage hinge all our hopes of getting a good crop of their products. Just lately, how bitterly cold has the wind been! how intensely cold, and keen the frosts at night! If the bloom has managed to pull safe through such a time, then has it been hardly indeed. Naturally, it has been a period of intense anxiety to fruit growers. Men who embark in hardy fruit culture need be made of iron to be able to pass through such periods of anxious care as these Blackthorn winters invariably are. The chief hope that much of the bloom may have escaped harm lies first in its exceeding abundance, so much of it being easily spared, and also in exceeding dryness of the soil and air. The soil is indeed exceptionally dry, and because so arid there has been little humidity in the atmosphere at night. But in relation to overcoming the climatal conditions our springs now so commonly impose on horticulture, we have more and more to realise the very important part in production of fruits and tender vegetables that glass houses must play. That this fact is being largely recognised is evidenced in various directions by the truly immense breadths of glass houses being erected. Some day perhaps, should no legal decision interpose, we may see fruit culture under glass even of Plums, Pears, Cherries, and bushes enormously extended. For that reason, if for no other, it is difficult to regard the appeal to be made to the House of Lords *re* market glass houses assessment with other than profound concern. The decision then given may kill or give new life to the present expansion of food culture under glass. If, after seeing such a magnificent bloom promise on our trees of a great fruit crop, frosts materially destroy it, what a grave misfortune it would be indeed.—A. D.

Blackthorn winter, as country folk call the present season, when the above plant (*Prunus spinosa*) is blooming in the hedgerows, is conspicuous for cold easterly winds, frosty nights, and bright sunshine in the daytime. All this means careful attention in ventilating vineries and other houses in which there is tender foliage. Leave the ventilators of an early vinery open when the sun goes in and black clouds stop the supply of warmth, the keenness of the wind is then felt, and Vines suffer. Neglect, on the other hand, to re-open the ventilators directly the sun appears and the tender leaves are scorched. Ventilation is one of the most important points in Grape culture at this time of the year, and more particularly so if the roof of the house is low in the pitch, as in such cases the leaves scorch much more readily.—H.

THE YOUNG GARDENERS' DOMAIN.

GOLD PENMEN.

WITH the view of affording encouragement to young gardeners who strive to acquit themselves creditably in the literature of gardening, marks are accorded to the contributions on their merits in M.S. form—not as they appear when corrected. Some require much more preparation than others, and those writers are wise who preserve a copy of the articles which they send for publication, and take note of the treatment to which they have been subjected. The writers who have obtained the greatest number of marks during the past six months are “Nil Desperandum” and “Semper,” who thus entitle themselves to the “Fountains.” We should like to publish the letters they have sent in acknowledgement of the articles “more powerful than the sword,” but pressure on space forbids. They will not be the less satisfied by knowing they did not win easily, and one more article from each of two contributors would have placed them at the head of the lists. We extend, not to the winners only, but those losers who persevere, our best wishes for their future prosperity. Educated gardeners who are equally practical are the men of the future, and all the more accomplished gardeners of the present, who occupy the highest positions, are men who have striven the most perseveringly in the laudable work of self-improvement. They may have had to work and wait, but they have been equal to the requirements when opportunities have come.

FREESIA REFRACTA ALBA.

I THINK it would be almost impossible to find a winter-flowering bulbous plant with more excellent qualities than *Freesia refracta alba*. We have other bulbs, no doubt superior in some respects, but fail in the combined qualities which this plant possesses. In the adornment of the conservatory or greenhouse the white sweet-scented flowers are a grand acquisition, while in a cut state, for vase or buttonhole work, they are invaluable. They retain their freshness a considerable length of time—an important consideration where flowers for this purpose are in great request.

A good time to pot the bulbs is about the middle of August, using as a compost a fibrous loam, two parts to one of well-decayed leaf mould, and a fair sprinkling of coarse sand and wood ashes, which tends to keep the soil sweet. The largest bulbs should be selected. We find 5-inch pots large enough for five bulbs. They are potted moderately firm, and are afterwards stood out of doors covered with ashes. As soon as growth appears we remove them to a cold frame, where they are allowed to grow steadily, staking being attended to as it becomes necessary.

I find *Freesias* require careful watering, especially before the pots are filled with roots, when a little weak liquid manure benefits them. This may be continued with advantage till the bulbs are almost ripe. To

insure good flowers the following year the bulbs must be thoroughly matured in the sun—in fact, they will almost stand baking.—ASPIRANT.

THE KITCHEN GARDEN.

How beneficial it would be for us to leave the glass structure for a time and take a turn at that important branch of all establishments—viz., the kitchen garden. Generally speaking it is feared this is too much neglected by young gardeners. Perhaps a cursory glance at the growing crop is all that is bestowed, and the exclamation follows, “Oh! it's only a row of Peas or Beans, or a plot of Cabbages, as the case may be; of what use are those things to us?” Has it ever occurred to us of what importance in after life a knowledge of this branch may be? I am afraid to some of our craft it may seem “lowering” to study the kitchen garden, but calling to mind a few of our prominent men, shall we not find them excellent practitioners in it? and hence its importance to young gardeners. Where is the loss? None whatever; on the contrary, a great store of knowledge if we will but gather it.

It may not have been given to us all to take our turn with the spade. Could we not make up for shortcomings by a general observation of the operations in the kitchen garden? The year is not too far spent if we commence at once. True, many seeds will have been sown, but we should take stock of the time of sowing, distances of rows, and note the results, making an entry in a diary kept solely for the purpose. As we get up to date we should take a turn round the kitchen garden each evening, observing the different operations of the day. By so doing we should obtain a thorough insight into the system of kitchen gardening, at the same time learning the names of the several vegetables. How useful it will be for us to know the season different varieties of Cabbage, Cauliflower, Broccoli, and Peas came into use for the table, calculating the time from the sowing of the seed, and entering in our diaries. As autumn comes on we should note the different methods of lifting roots and storing, also the structures they are stored in.

What shall we not learn in the season from noting the different methods of preparing the ground for the reception of crops, the site for this and that, why this piece of ground is trenched, and the benefits derived from it? We could in this latter case advantageously study the subsoil of our garden. Then there are the various methods of manuring and manures, and a very important item, the rotation of crops. We must not forget the forcing of different vegetables. Potatoes, Seakale, and Asparagus, for instance. We shall learn much from observing the ways of so doing. My subject is an extensive one—one that young gardeners must not lightly deal with. It requires perhaps more study and energy than we think, but we may overcome all obstacles by diligent perseverance, and should strive to make it our endeavour to hold our own against all comers in the days to come.

Yet another item, and not a small one. There is generally outside fruit culture in connection with the kitchen garden. We may be excellent practitioners under glass, but how would some of us shape if told to take charge of the outdoor department? We should endeavour to get a good insight into this, it will be useful in the long run.—SEMPER.

BANANAS, OR MUSAS.

THERE are two ways of growing Bananas—namely, in borders and in pots. They do well both ways, but I think borders are the best—at least, better fruit seems to result from them. In making the borders have them, if possible, about 36 inches deep. Provide about 10 inches of drainage, and if there are a couple of hot-water pipes in the rubble for bottom heat, so much the better. Over the drainage place inverted turves, as if for a Vine border, and fill up with a compost of mellow fibrous loam, which has had a good sprinkling of crushed bones and lime rubble added to it, leaving about 4 inches for water. Leave the suckers on the old plants till about a foot high, and then pot, using pots according to the amount of roots detached, not crowding, and potting moderately firm. When well rooted, but before getting root-bound, plant in the borders, making the soil fairly solid. If the borders are occupied until they are vacant the plants must be repotted, or they will receive a check. Copious supplies of water are required during the growing period, but a sodden condition of the soil must be carefully avoided during the winter months. With the exception of the one or two suckers required, keep off all unnecessary ones, as they greatly weaken the larger plants. Provide new borders for every fresh plantation.

Whenever the weather permits syringe thoroughly twice a day, maintaining a warm moist atmosphere. Keep the temperature at a minimum of 70° by night, dropping it to 65° in very sharp weather, allowing a rise of 5° by fire and 10° by sun during the day. Give air at 80°, increasing gradually, closing and syringing as soon as it falls below 80°. Damp down regularly, not omitting to do so during the last round at night.

Feed the plants slightly, and seldom, until the fruits are well set, then gradually increase the nutriment. Liquid cow manure I have found the best to use, with a change now and again with some well proved chemical fertiliser. Keep the house rather dry when the plants are in bloom, tapping them lightly with the hand about midday. The plants vary in arriving at maturity, and I do not know that there is really any specified time during which a sucker will produce fruit.

When the fruits assume a golden colour, and with a slight pressure of the hand can be parted from the fruit-stalk, they should be taken off as they ripen and laid on a sunny shelf for a few days in a warm house, when they will develop their maximum flavour. As soon as the fruit is all gathered throw the old plants away. *Musa sapientum* is the most commonly grown, but *M. Cavendishi* succeeds in a little less heat. Now, Y. G. D. Banana growers, let us know the quickest record of growing and fruiting the plants.—TIM.

FRUIT FORCING.

Cucumbers.—Plants in houses and hot-water heated pits must be syringed twice a day, but let it be done judiciously. The dusting of the pipes with a little flowers of sulphur usually suffices to keep red spider and white fly in subjection and also prevents fungi spores from germinating. Plants growing in manure-heated frames will not need syringing so often; a sprinkling at closing time will be sufficient on bright days, and not at all when the weather is dull. Give liberal, but not unnecessary, waterings of liquid manure at the mean temperature of the house to plants in full bearing. Avoid overcropping and overcrowding the growths. Attend to the necessary stopping, thinning and tying, keeping a succession of fruit growth. No more fire heat should be used than is absolutely essential. Make another planting if necessary, so as to maintain a supply of fruit exceeding rather than equal to the demand.

Melons.—*Early Plants.*—When the fruit begins ripening lessen the supply of water at the roots, but not so as to distress the plants, for if the foliage has been kept clean and the roots are in good condition a second crop may be had. Withhold atmospheric moisture, or rather keep water from the fruit, and provide a circulation of dry, warm air, increasing the temperature to 70° to 75° artificially, and 80° to 90° with sun heat. Cut the fruits before they are very ripe, keeping them in an even temperature for two or three days. If any fruits show a tendency to crack, cut the shoots about half way through with a sharp knife a few inches below the fruit, and diminish the supply of water at the roots and in the atmosphere, leaving a little ventilation constantly to prevent moisture condensing on the fruit.

Succession Plants.—Continue fertilising the flowers when fully expanded, the atmosphere being kept drier and warmer and ventilation carefully attended to. Stop the shoots at the time of fertilisation one or two joints beyond the fruit. Earth the plants with some rather strong and rich loam after the fruits begin swelling, ramming it firmly, to secure solid fruit, and place a little fresh lime round the collar to prevent canker. Plants swelling their fruits may be syringed in hot weather about 3 P.M., damping the floor several times a day, and in the evening sprinkle the floor with weak liquid manure. Shade only to prevent flagging, and ventilate freely in favourable weather. Maintain a day temperature of 80° to 85°, or 90° with sun heat, closing between 80° and 85°, and if an advance of 10° or 15° be made after closing it will assist the fruit in swelling, and lessen the necessity for fire heat at night, but it must be accompanied by atmospheric moisture. If thrips appear fumigate moderately on two or three consecutive evenings, taking care to have the foliage dry.

Train the growths out in pits and frames, still maintaining a good bottom heat by linings, and employ thick night coverings over the lights. Sow seeds for raising plants for placing in pits and frames as they are cleared of bedding plants. Add more soil to the hillocks as the roots push through the sides of the mounds, which must be repeated at intervals until the allotted space is filled. Any young plants that are likely to become root-bound should be shifted into pots a couple of sizes larger to keep them in steady progressive growth until the beds or hillocks are prepared for them.

Peaches and Nectarines.—*Earliest Forced House.*—On early varieties the ripening fruit and foliage must be kept dry, but the border must not be allowed to become very dry. As the fruit of the later varieties will not be ripe for some time, keep the atmosphere moist by frequent sprinkling during the day, syringing in the morning, and again when closing the house. The night temperature will be perfectly safe at 65° to 70°.

Fruit Stoning.—During the stoning process the trees must not be hurried, 60° to 65° at night is ample, and 70° to 75° by day, avoiding sudden fluctuations. A little air admitted at night will prevent the deposition of moisture on the foliage to any serious extent, and may be increased when the sun acts on the house, yet without lowering the temperature, which should always advance with the increased power of the sun and a corresponding increase of ventilation. Avoid fumigation as far as possible, as it dries the atmosphere, and not unfrequently cripples the foliage. Early closing is to some extent an advantage, but it must not be continued too long. It is also advisable to allow a little extra latitude to the growth, but on no account permit foliage to be developed that must afterwards be removed in quantity. Keep the inside border well supplied with water, and feed judiciously with potassic and phosphatic foods.

Trees Swelling Their Fruits.—These swell most at two periods—viz., after setting until the commencement of the stoning process, and after stoning. The first is materially, if not entirely, influenced by the previous storing of matter in the trees and the available food in the soil. A genial condition of the atmosphere accelerates the swelling of the fruits and the means employed to secure good root action, which is best effected by a judicious and gradual regulation of the growths by the processes of disbudding and thinning the fruits. Overcrowding is a great evil, but large reductions of foliage at one time as well as fruit are not good. The more vigorous the tree the greater is the danger of the fruit being cast in stoning, and the evil is afterwards increased by severe disbudding, also by a close and moist atmosphere. In the last swelling after stoning tie the shoots down, so that the fruits may be fully exposed to the light, but moderate extension of the lateral growth will materially assist the

fruit in swelling, care being taken that the principal foliage and fruit be not interfered with. Supply water thoroughly to inside borders when necessary, and liquid manure to weakly trees.

THE KITCHEN GARDEN.

Broccoli.—As stated on page 335, early sowing of main crop and late Broccoli is far from desirable in many cases. If it has been done there ought to be no delay in pricking out the plants in fine soil and an open position, disposing them not less than 4 inches apart each way. All plants should be moved to their final quarters with the aid of a trowel, saving a ball of soil about the roots. By sowing the seed late in April, thinly, either broadcast or in drills, and quite in the open, abundance of sturdy plants should be ready for putting out quite as soon as wanted. Chou de Burghley or Cabbage Broccoli also gives the greatest satisfaction when raised late. At this date, however, there must be no failures, and in order to preserve the seed from small birds, either moisten them in a cloth and roll in red lead prior to sowing, or net over the seed beds. Directly the seedlings show through the soil dust with soot and lime to protect from slugs and flea.

Retarding Broccoli.—Hot days have brought on Broccoli faster than desirable, and gluts are complained of. In a few days the bulk will be either used up or spoilt, and when Broccoli is most wanted, owing to a dearth of other vegetables, it will be scarce. Model, Latest of All, Late Queen, and other extra late varieties may be retarded somewhat by carefully lifting, saving as much soil as possible, and laying in on a north border. According as each line is laid in give the roots a good watering. Cover with mats while the sun reaches the border.

Kidney Beans.—Early breadths of these frequently produce much appreciated crops. They may be grown on a flat ridge formed at the foot of a south wall and also on a south border. Sion House, Ne Plus Ultra, and other extra early varieties are the best for this sowing. Sow the seed thinly in drills 18 inches apart. If it can be done protect the plants during cold nights with benders and mats.

Broad Beans.—Only the Broad Windsor type should be sown at this late date. If the early sown seed has come up badly fill up blanks, Broad Beans transplanting readily in showery weather. Mould-up advancing rows lightly to steady the plants.

Beet.—The strong growers, including Pragnell's Exhibition, are best sown late, as it is a preventive of coarseness of root. The same remark applies to the Turnip-rooted type where this, owing to the shallowness of the ground, has to be grown for storing. Beet should have a freely worked, finely divided soil, and if any solid manure is dug in it must be buried deeply, or forking of roots may occur. Sow thinly in drills 12 inches to 15 inches apart.

Celery Beds and Trenches.—Trenches are not indispensable for Celery. Some of the finest produce seen at the summer shows is grown either on the level ground or on raised beds enclosed by stakes and boards. Prepare the ordinary garden soil by freely mixing with it well decayed manure, fresh loam if it can be spared, and charred soil and ashes from a garden slow fire. In this well prepared plants may be put out 15 inches apart each way, doing this early in May. The blanching is cleanly effected by bandages of brown paper. Trenches for growing either early or maincrop Celery should be got ready early now, as this admits of the work of planting being done expeditiously, and affords an opportunity for cropping the ridges between the trenches with Kidney Beans and Lettuce. Celery forms a good succession to Borecole, Brussels Sprouts, and Broccoli. The trenches may be 15 inches to 18 inches wide, allowing the greater width when the Celery is to be planted in double lines. Spaces 4 feet wide between the trenches are not too much, especially if they are to be cropped. The trenches should not be deep, particularly in the case of cold clayey soils. Move the top spit and distribute this evenly between, leaving the loose soil or shovellings in the trench. Fork a liberal dressing of nearly decayed manure into the trench.

Seed Failures.—Failures to secure a good even plant are not always due to bad seed. More often than not the cultivator is at fault, sowing the seed too early, or not protecting sufficiently from enemies. If there have been failures commence remedial measures at once. It is somewhat late to sow more Onion seed in the places where that first sown has failed, but when the seedlings are about 4 inches high they transplant readily in showery weather. The long-rooted Beet transplanted rarely forms good roots, but if more seed is sown where the blanks occur directly these are seen appearances will be saved, and serviceable roots probably result. The Turnip-rooted transplants fairly well, and may be employed for filling up gaps. Carrots move badly, and more seed should be sown where failures occur. It is not yet too late to start afresh. After the middle of May Nantes, Horn, Model, or Guerande may well be sown in preference to coarser varieties, the roots of these keeping admirably. If the seed is sown in drills 10 inches apart, and the plants not severely thinned, a surprising weight of roots of superior quality can be had from quite a small breadth of ground. If more seed of either Salsafy, Scorzonera, or Chicory has to be sown, take extra pains with the preparation of the ground, making this very fine, and not forgetting to moisten the drills if dry. Even Parsnips may yet be sown with a good prospect of serviceable roots being obtained. If whole breadths of Turnips are eaten by the flea, hoe over the ground and sow more seed at once, and at the same time apply a light sprinkling of guano or a dressing of soot. Small sowings of Turnips at short intervals are preferable to sowing larger breadths less often. It is not yet too late to sow Parsley, strong young plants transplanting well. Lettuces should now be sown at intervals of a fortnight or so where the plants are to heart in. Sowings may yet be made of early Broccoli, autumn Cauliflower, Borecole, Brussels Sprouts, and Savoy Cabbage. Avoid sowing thickly.

THE BEE-KEEPER.

DYSENTERY.

BEES, like animals, are subject to disease, and one of the commonest is dysentery. Bee-keepers have often themselves to blame if troubled with it to any serious extent, as it is caused by carelessness in a variety of ways. Dysentery usually appears during late winter or early spring, and stocks may be known to be affected with this disease when the combs and floor board are covered with a chocolate or yellow disagreeable smelling excrement voided by the bees. Also when the bees take a flight on fine days they soil everything in the neighbourhood of the hives.

Bees after a long confinement in winter, will at the first opportunity take a spring cleansing flight, when the ordinary faecal matter will be much in evidence in the neighbourhood of the apiary. If bees are in good health in well constructed hives, and are able to take a flight occasionally, they will not disfigure their surroundings again. The case, however, is quite different when the bees have dysentery, as the faecal matter gradually becomes darker in colour, and if steps are not taken to cure the disease the bees will succumb. If a colony of bees is so reduced in numbers that there are not sufficient to keep up the temperature of the hive, and those that remain are swollen and scarcely able to leave the hive, it will be of little benefit uniting them to another colony, as they would probably not recover. If the combs are very much soiled it will be an advantage to melt them down, but if the frames are in good condition they may be used again.

CURE FOR DYSENTERY.

If the affected bees are in a frame hive they are much more easily manipulated than when they are in a straw skep. They should be examined during the warmest part of the day. Have a warm dry hive close at hand, into which should be placed all combs containing brood (if any) and sealed stores, but not more than the bees can cover. The division board may be drawn close up to the combs, and the whole covered with several thicknesses of warm material, the stock being placed on the same spot as the original hive occupied. Feed with warm syrup daily, only giving sufficient for their daily requirements. It is much better to give them a little each evening than to supply them with a greater quantity, so that they are unable to carry it down for several days, when it will become quite useless for the purpose for which it was intended.

Warm weather has a great effect on bees troubled with this disease, and if the above instructions are carried out the benefits arising from it will be apparent in a few days. A dry hive, warmth, and good food are the chief essentials in building up a strong colony from an affected stock. Owing to the mild open winter there has been much less dysentery than usual amongst the bees. It has only been observed in a few instances this spring, and in each case it could be accounted for, not from a damp hive, but owing to late feeding last autumn.

SPREADING BROOD.

There are few bee-keepers in the country who keep their bees in the modern frame hive who have not at one time or the other tried their hand at spreading brood. In case this question may not be understood by all, we may briefly state that spreading brood is practised by bee keepers in their attempt to fill the hive with bees and brood more rapidly than would be the case if the bees were left to themselves. How is this done? By closing up the division board to the combs covered by the bees, and every few days placing a frame of fully drawn out comb or foundation in the centre of brood nest. Others, again, place the empty comb on the outside next to the comb containing brood and eggs. This plan is preferred to the former, for if extra combs have to be added it is better to place them outside of the brood nest than in the middle, which would have the effect of separating the bees, and if a cold night should set in they would cluster closer together, and the brood in the outside combs would be chilled.

We have experimented under both systems on many occasions. The first time the former plan was adopted. In one hive the bees were fed with warm syrup daily, and as it was a fairly strong colony and the weather was finer than usual at that time, success crowned our efforts. The other hive, although treated in the same manner as regards stores the previous autumn, was much better off for sealed stores at that date (end of April), so instead of feeding them the same as the bees in the other hive, a few inches of stores were uncapped or bruised, which is quite sufficient every other day, and a frame of comb given as required was rapidly filled with brood. They both stored a surplus; but as there is so much danger attached to the operation, we do not recommend it. If the bees are supplied with ample food, and there are sufficient frames outside the brood nest, the bees will take possession of them when it is necessary to extend their brood nest.

Bees will not increase at a rapid rate if left to chance and are short of stores; thus it is that some bee-keepers recommend spreading brood so strongly is owing to the fact of attending to their bees, and supplying them with the necessary food when required. — AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers; but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Daffodils from Sandy Soil (R. C. Notcutt).—The flowers you have sent are remarkably good as produced by plants in sandy soil. The different varieties are well represented and the colours bright and clear. The other flowers are unnamed varietal forms of *Pyrus* or *Cydonia japonica*, and not uncommon.

Uriah Pike Carnation (J. P. Leadbetter).—You ask our opinion as to any merit the bloom you have sent may possess. It is more than 4½ inches across, and the outer petals 1½ inch in diameter. It thus possesses what some persons regard as a great merit—size. As the bloom is "one of many of similar dimensions," it is perhaps a sport—a sort of *Uriah maximus*.

Andromeda Poisonous (Enquirer).—Your experience is unfortunate but interesting. You say, "Several sheep have died, and on their examination it was found they had eaten leaves of *Andromeda floribunda*." There is a record of thirty-seven sheep being poisoned by this species in America, of which it is a native, and though the animals were subjected to treatment, eighteen of them died. *Andromeda ovalifolia*, a native of Nepal, is poisonous to goats which eat it, and *A. polifolia*, a native of the North of Europe, is fatal to sheep. It may not be generally known that another Ericaceous plant, *Kalmia latifolia*, is distinctly poisonous. It is a native of North America, and it is said that the Indians used to prepare a decoction of the leaves to destroy themselves; and it is further stated that in consequence of the flesh of partridges and pheasants which have fed on the leaves having been eaten, that two cases of death are recorded. The green growths of *Azalea pontica* are said to be fatal if eaten by cattle and sheep.

Chemical Manure for Roses (J. H. Doyle).—Chemical manures are not generally used by rosarians in England. They rely mainly on natural manures, those from piggeries and cow-sheds being preferred, the latter especially for dry soils. An occasional dressing of lime is given in addition, and perhaps no finer Roses are obtained than by the long proved methods indicated. Still, undoubtedly chemical manures are of great service to Roses, not instead of natural manures, but supplementary to them, unless the soil be rich in vegetable matter. Elaborate formulæ are more imposing in appearance than essential, and cannot be equally applicable to all soils. If you can obtain basic slag, and add half a pound of it with a dressing of ordinary manure for trenching well down into each square yard of land, it will be of permanent value. As a general application, if you use two parts superphosphate of lime and one part either sulphate or muriate of potash, whichever you can best obtain, or in the absence of either kainit, and apply at the rate of 4 ozs. to the square yard just before the buds start in spring, then when growth is in progress apply less than half the amount of nitrate of soda if the ground is of a hot dry nature, or sulphate of ammonia if it is the opposite, your Roses will be materially assisted. During dry summers, which we have heard are prevalent in Tasmania, mulching with manure, to remain on the surface to decay, would be of great advantage.

Propagating Poinsettias (*G. O. L.*).—If the old stems are cut into lengths of two joints, inserted in sandy soil, and placed in a warm house, they will soon commence growing and form roots. This is probably the easiest way of raising these plants. When cuttings of young shoots are preferred, place the old plants in heat and keep them well syringed until growth commences. When the shoots are 3 inches in length slip them off with a sharp knife and insert them singly in thumb pots, placing a little sand at the base of each cutting. If kept close and shaded from the sun under hand-lights they will soon emit roots.

Asphalt Path with Cold Coal Tar (*Somerset*).—It is necessary to boil the coal tar in order to prevent its running on to the Box edging, and the material with which the tar has to be mixed when boiling must be perfectly dry, otherwise the asphalt will not set hard. The use of eold or unboiled gas tar is sometimes advised for forming garden paths in the manner you describe, and though it answers for keeping down weeds in places where there is nothing to injure by the tar coming into contact, the practice cannot be recommended when the edgings are Box, especially as the paths will be narrow. The tar sinks into the soil, and the tar water proves injurious to vegetation. The cost of an iron copper is not great, and with it and a few bricks, also the requisite fuel, you may easily boil the tar, which we advise, as we have found unboiled disastrous to "live" edgings, and besides, paths made with it turn soft in hot weather. Of course it must be used cold, or nearly so, on the path or about the edging.

Stokesia cyanea (*M. F. M.*).—If planted in light warm soil in favourable situations it will expand its profusion of lavender blue flowers some 2 or 3 inches across during the month of October. When the soil is cold or stiff it is best grown in pots plunged in ashes during the summer, when it may be introduced into the cool greenhouse, there to expand its blossoms. It grows 2 feet high, and is a first-class perennial. It is not easily increased by division owing to the tufted or conglomerate growths on the rootstock. So closely are they packed in that they cannot be separated without considerable sacrifice. It is, however, readily increased by root cuttings, and as roots may be had in plenty there is no reason why so good a plant should not be more generally grown. This may be accounted for in a measure by its lateness in flowering, when visits to nurseries are less frequent than in the spring and summer months. By lifting a plant and selecting some of the strongest roots a good stock may be secured. Cut the roots into lengths 2 inches or thereabouts, and insert them round the inside of pots in sandy loam, leaving the top just visible. By placing them at once in brisk heat good plants may be secured by the ensuing autumn. In two or three weeks or less time, according to the heat they have been subjected to, they will commence to break freely from the apex of the root cutting, and when of sufficient size they should be moved to a cooler place, subsequently potted and hardened.

Cucumbers Gumming (*H.*).—This serious disease generally arises from an excess of nitrogenous matter, in conjunction with considerable moisture at the roots, and in an atmosphere unfavourable to evaporation from the parts above ground, hence very common in manure-heated pits and frames late in the summer, and at other times when the temperature rules relatively low. The application of linings in such cases usually affords prompt relief, especially if accompanied with a little air. This malady also appears in houses under similar circumstances, the bed or border compost being too rich in nitrogenous matter, in proportion to the available phosphoric and potassic elements, hence a top-dressing of these acts beneficially, especially with a somewhat higher, and in consequence relatively drier atmosphere. Under the circumstances you describe we have found a light top-dressing of dissolved bones, dry and crumbling, three parts, sulphate of potash one part, and sulphate of iron and magnesia in equal proportions, a quarter part, mixed, using 2 oz. of the mixture per square yard, and preferably with a little soil, especially if the roots are on the surface. This will wash-in, and may be repeated every fortnight or three weeks. But the main point is to maintain a brisk temperature, say 70° to 75° at night, and in the daytime a rise to 90°, 95°, or 100° with sun. The moisture need not be reduced, and certainly not increased, but still maintain genial atmospheric conditions to insure the proper development of the fruit and keep the foliage in health. In the matter of root moisture supply water moderately, and only when required to maintain the foliage fresh and promote a steady progressive growth. Rely most on the high temperature, and the plants will grow out of the disease unless otherwise affected.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*A. T. P.*).—1, *Cydonia Maulei*; 2, *Prunus Pissardi*; 3, *Kerria japonica flore-pleno*; 4, *Cerasus* (*Prunus*) *Padus*. (*B. H.*).—1, *Omphalodes verna*; 2, *Primula japonica*; 3, *P. farinosa*; 4, *Doronicum plantagineum*. (*H. G. A.*).—1, *Odontoglossum excellens*; 2, *Cypripedium villosum*. (*J. O. A SATISFIED GRUNT.

A GOOD grumble is the farmer's privilege, and we doubt not that the spirit of dissatisfaction which is his most distinguishing trait has had much to do in alienating the sympathy of other classes when the farmer has had real woes and good cause for grumbling.

Of course, the favours of fortune are not always evenly distributed, and a season that may be the reverse of favourable in some districts may be far above the average in others. The agricultural year just closed may not have been the best from the grazier's point of view, but we fancy that the occupiers of mixed farms will, as a body, acknowledge that, for them at least, things have taken a turn for the

better, and though they may be reluctant to answer inquiries with anything but a grunt, still it may sound like a grunt of satisfaction.

Last year's cereal crops were, taking them all round, hardly as good as those of 1896. Wheat was not so good, Barley was fair, and Oats decidedly deficient. Wheat was rather thin of plant, and made a bad start, but we have found that the yield of grain was better than we expected; and though nothing above the average, yet when reckoned up at the much improved prices that have ruled, the net return per acre is the best we have had for many years.

Barleys were fairly bulky in straw, and were very fine in quality. The yield, though fair, was much reduced by want of rain at a critical time, the grain not being finished as it should be. Ours is only average Barley soil, being rather liable to suffer from drought. An average price, however, of 32s. is nothing to grumble at, and here, again, the return per acre shows great improvement.

The Oat being a moisture-loving plant, it is not surprising to find the crop below the average; it suffered from drought in the earlier stages of growth, many shoots becoming blind, and never producing an ear at all. This naturally diminished the crop considerably. On thrashing, however, we find the yield not so bad, and the price, 22s. per quarter, helps the return to cut quite a respectable figure. Facts speak for themselves, and when we find that our grain crops have produced £2 10s. per acre more this year than last, we cannot but look on this result as eminently satisfactory.

Improvement in prices has been the chief factor in bringing about this happy result, and low prices are what the British farmer has been suffering from most, for neither farmers nor anyone else can go on producing at a loss for any length of time.

Potatoes were much below the average, only two or three kinds giving fair returns as to crop. Up to Date was far the best, being just double the weight of Bruce growing by its side. Imperators did fairly, as did Reading Giant, but the latter showed great tendency to disease. Small crops and light market supplies have resulted in much higher prices, which large foreign importations have been almost powerless to affect.

Farmers who were satisfied with £3 per ton, and sold out at that price before Christmas, would not find their pockets very well lined. Four tons per acre was this year more than an average crop, and though £3 per ton was an improvement on the price of the previous season, yet 4 tons at £3, or £12 per acre, was not enough to pay the grower and give him a profit.

Those, however, who had an eye for statistics, and could form a good estimate of the Potato crop of the United Kingdom, have, by acting upon the knowledge thus gained, made a very fair thing out of their Potato harvest. A sudden rise to £5, and even as much as £6 for extra quality, took place about Christmas time, and though the foreigner stepped in and damped things down a little, prices never fell much, and at the time of writing they are as high as ever, with a good prospect of further material rise. Unfortunately farmers have very small stocks left, having been tempted by the bird in the hand—some, in fact many, having entirely cleared out, so that the profit from any further rise must go into few hands. So convinced, however, are we of the certainty of a Potato boom that we are refusing £5 10s. per ton with scorn, and putting our small remaining stock by for another month. We advise others to do the same.

This has been a good year for sheep; last season's lambing was excellent, and though pastures suffered from drought before mid-summer and Turnips were likely at that time to be very short afterwards all came right. Winter keep has been plentiful everywhere, and those who had looked forward with dread to a big cake bill and a generally expensive winter have had great cause to rejoice. Sheep have been very healthy, and there have been few losses; the lambing has been again favourable, if the crop of lambs has not been quite as large as last year. Sheep markets have been fairly good all the year until the last month, when, as usual in April, they were overcrowded with Turnip-fed animals. Why farmers should persist every year in keeping all their sheep until April and then pouring them into the markets in three or four weeks has long been a puzzle

to us. We think with a little patience the prices will soon recover. We certainly think the flockmaster has had a good year, or at any rate the chance of one.

Cattle have been the blot on the balance-sheet; animals which were bought at or stood the grower to a good store price twelve months ago did fairly well if fed off grass and turned over quickly, but those who like to produce a good stall-fed bullock or heifer, either for Christmas or later, have indeed undergone bitter disappointment. Prices were very poor in December, but they are even worse now, 6s. 6d. per stone of 14 lbs. being an ordinary price.

This depression in beef prices has not so much affected the price of stores, which are anything but cheap, and promise no margin for profit if the price of meat remains at its present level. Pork has sold fairly, but the enhanced price of foodstuffs must reduce profits here.

Milk, butter, poultry, and eggs have met with much greater competition from home production as well as from abroad, and prices have suffered a little, but the consumption increases as prices decrease, and we cannot complain as long as we get our share of the spoil.

We trust that our little grunt of satisfaction may find an echo from many others who, like ourselves, have found that farming is on the mend.

WORK ON THE HOME FARM.

Since writing last week we had two more very wet days, and although we had wanted rain badly we were rather glad when the weather took up again. The last few days have been fine, with slight morning frosts; the rain has done endless good, land that was rough and dry has fallen like lime, and late spring corn must go in well. Early sown Oats and Barley had felt the frosty nights; the rain has had a wonderful effect on these crops, and they are running on fast.

The nitrate of soda came at last, and is being sown on the Wheat. The latter has grown so fast and looks so well that a neighbour suggests that we are using the top-dressing needlessly. May frosts have to be met yet, however, and as the plant is very thick on the ground we think the fillip will be needed after all. Wheat harrowing still continues; it has rather a drastic effect, but Wheat likes knocking about in spring.

Mangolds are going in splendidly, the land is fine and yet full of moisture, and there should be no doubt about getting a plant; 6 lbs. per acre of good seed should be quite enough to sow now. Some people sow a little Swede seed amongst the Mangold, but we do not like the system, as the Swedes, even only a few, seem to have a smothering effect, and Mangold mixed with Swedes never seem to get so large as when they have the ground to themselves.

Grain is getting dearer, and both pig and hen corn are becoming decidedly expensive. Maize, however, can yet be bought at 20s. per 34 stones. This is good food for growing pigs intended for autumn feeding. The Maize should be scattered (unground) in the yard, the animals will then pick it up grain by grain, and thoroughly masticate it, which they will not do if it is given split in a trough. Fine sharps can be bought at 8d. per stone; this as a paste is good for fowls in the morning, and if followed by Maize for the later meals, the fowls will keep healthy and lay well. We are only speaking of farmyard fowls, however, not of such as are kept in confinement.

We have a splendid supply of Mangold, and it is quite astonishing how many the fowls, old and young, can eat if they have the chance.

REMARKS.

17th.—Brilliant early; frequently cloudy in afternoon and evening.
18th.—Overcast early; generally sunny after 10 A.M.
19th.—Generally sunny day; fine night.
20th.—Fair with frequent, but not strong, sunshine.
21st.—Generally cloudy till noon; bright afternoon.
22nd.—Overcast morning; sunny at times after 2 P.M.
23rd.—Sunny almost throughout; bright night.
Another average week except that there has scarcely been any rain at this station.—G. J. SYMONS.

STOVE & GREENHOUSE PLANTS, FERNS, &c.

Buyers of these are invited to inspect one of the largest stocks in the Kingdom of well-grown, clean, healthy plants in various sizes and immense variety at **OLDFIELD NURSERIES, ALTRINCHAM. COLLECTIONS** (our selection only):—12 vars. Flowering Stove Plants from 18/-; 12 vars. Foliage Stove Plants from 18/-; 12 vars. Greenhouse Plants from 12/6; 12 vars. Caladiums from 12/-; 12 vars. Crotons from 24/-; 6 Epiphyllums from 7/6; 12 distinct named Gloxinias from 18/-; 12 distinct Ferns for Stove from 9/-; 12 ditto for Greenhouse from 6/-; 12 different Adiantums from 6/-; Seedling Ferns for Rockeries, &c., from 3/- per doz. **CATALOGUE**, with description, prices, cultural hints, post free.

CLIBRANS, Altrincham and Manchester.

COOLING & SONS' NEW ROSES FOR 1898.

NEW HYBRID BOURBON, PURITY.—Card of Commendation, National Rose Society. A grand New Rose colour pure white, with faintly flushed centre. As a Pillar and Garden Rose, and as a variety to cut for market work, it is bound to become a great favourite. Strong plants, 7/6 each.

NEW H.P. ROSE, R. B. CATER.—Another of the late Mr. Hy. Bennett's seedlings, a grand addition to its class; colour bright magenta-carmine, most beautifully shaded. Strong plants, 7/6 each.

NEW RUGOSA, DELICATA.—An exceedingly pretty and distinct new seedling Rugosa, which will be found a welcome addition to Garden Roses; colour, soft rose, double flowers of good size, blooming continuously, and in clusters. Strong plants, 3/6 each.

We have a large collection of Tea-scented and Garden Roses of all kinds in pots. New May List, post free.

GEO. COOLING & SONS, THE NURSERIES, BATH.

PLANT NOW Carnations, Pansies, Phloxes, &c.

NEW CATALOGUE (No. 503) of HERBACEOUS and ALPINE PLANTS, also of FLORIST FLOWERS, &c., Now Ready, and will be sent post free on application.

PRICE 1/-; POST FREE, 1/2½.

MUSHROOMS FOR THE MILLION

By J. WRIGHT.

Office: 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

No. 932.—VOL. XXXVI., THIRD SERIES.

CARTERS' HOLBORN PRIMULA.—Our Prize Strain of the beautiful winter-flowering conservatory plant is the finest in cultivation. We were the originators of the blue variety now so popular. Fresh seeds, in all colours, mixed, including white, scarlet, blue, and pink. In Sealed Packets, price 2/6, 3/6, and 5/- each, post free.

CARTERS' BRILLIANT CINERARIA.—The very finest strain ever submitted to public notice. Awarded Highest Prize, Medal Royal Botanic Society, 1897, Royal Horticultural Society, 1898. A customer recently sent us blooms measuring 3½ inches across. Fresh seeds, all colours, mixed. In Sealed Packets, price 2/6, 3/6, and 5/- each, post free.

CARTERS' VICTORIA CALCEOLARIA.—Our grand strain is the very perfection of scientific culture, being compact in habit, and brilliant in colour and size of blossoms. A customer writes: "The plants were a perfect picture, many with 600 blooms; we took first prize." Fresh seeds, all colours, mixed. In Sealed Packets, price 2/6, 3/6, and 5/- each, post free.

CARTERS' INVINCIBLE GLOXINIA.—We have brought this fine summer decorative plant to the highest excellence. H.R.H. the Princess of Wales greatly admired our exhibit at the Temple Exhibition last summer, and was graciously pleased to pronounce it an "exquisite display." Fresh seeds, all colours, mixed. In Sealed Packets, price 2/6 and 5/- each, post free.

CARTERS', THE QUEEN'S SEEDSMEN, 237, 238, and 97, HIGH HOLBORN, LONDON.

CLEARANCE SALE.—100,000 BEGONIA TUBERS, large erect flowering. Singles, 12, 2/-; 25, 3/6; 50, 6/-; 100, 11/-. Doubles, same price. Smaller, 12, 1/6; 25, 2/6; 100, 8/-, for cash.—**JOHN WELLS, Begonia Nursery, Ryarsh, Maidstone, Kent.**

CACTUS DAHLIAS.—Annie Jones, Fusilier, J. E. Frewer, M. W. Noble, Mrs. L. Seymour, Lady Penzance, Matchless, Gloriosa, Mrs. Barnes, and three others for 4/- List free.
W. BAXTER, The Nurseries, WOKING.

PROFITABLE FRUIT GROWING FOR COTTAGERS and SMALL HOLDERS of LAND. The Gold Medal Prize Essay. By J. WRIGHT. Written for the Worshipful Company of Fruiterers. Demy 8vo, price 1/-; free by post, 1/3.—**JOURNAL OF HORTICULTURE Office, 12, Mitre Court Chambers, Fleet Street, E.C.**

CALCEOLARIAS, Yellow, best bedder. Extra strong well-rooted plants from cold frames; hardened. Plant now. 7/- per 100, packing free, for cash with order to **WM. CLARK, Hanover House, Llangarron, Ross.**

CALANTHE VESTITA BULBS.—Now is the best time to repot. A few dozen strong leading bulbs at 21/- per dozen, post free.—**J. GODFREY, Gardener, Bitterne Park, Southampton.**

J. C. STEVENS' HORTICULTURAL, SCIENTIFIC, and NATURAL HISTORY SALE ROOMS, 38, King Street, Covent Garden, London. Established 1769. Sales by Auction nearly every day. Catalogues on application or post free.

DEFY THE BIRDS by Buying our Noted **ROTLESS TANNED NETTING**, as supplied to the Principal Gardeners in the Kingdom. Orders over 5/- value are sent Carriage Paid. 100 yds. by 1 yd., 3/-; 200 yds. by 1 yd., 6/-; 300 yds. by 1 yd., 9/-. Can supply any length and width.—**UNIVERSAL SUPPLY ASSOCIATION, East Street Works, Reading. (Name Paper.)**

HEATING APPARATUS.—Medals 1875 and 1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2/6; post free, 2/10.—**JONES and ATTWOOD, Stourbridge.**

COTTAGE GARDENING; being an Essay to which the Royal Horticultural Society awarded Mr. W. EGERTON HUBBARD'S Prize, February 16th, 1870. By E. W. BADGER. Third Edition. Price 3d.; post free, 3½d.—**JOURNAL OF HORTICULTURE OFFICE, 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.**

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd., Leeds.**

ALL WHO WISH GRAND RESULTS should use **THOMSON'S IMPROVED VINE, PLANT and VEGETABLE MANURE.** This Valuable Manure is yearly growing in public favour. Can be had of all Nursery and Seedsmen, or direct from the makers, **WM. THOMSON and SONS, Ltd., Tweed Vineyard, Clovenfords, Galashiels, N.B.** Price Lists and Testimonials on Application. 1 cwt. and upwards Carriage Paid to all stations in Britain and Ireland. London Agent—**Mr. J. GEORGE, 14, Redgrave Road, Putney.** Agent for Channel Islands—**Mr. J. H. PARSONS, Market Place, Guernsey.** Also **THOMSON'S SPECIAL CHRYSANTHEMUM MANURE, ½ cwt.** Carriage Paid to all stations in Britain and Ireland.

Journal of Horticulture.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St. London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

THE SEASON.

Oh, to be in England, now that April's there!
So sang Browning, incited by some vision recalling to the absent poet's mind those charms of spring peculiarly our own. Alternating smiles and tears—warm rays and cold, weeping skies—coaxing and forcing back to life and beauty a thousand things—gladdening all, and filling many with hopes that may never be realised, fears that may be futile. Who shall foretell? One fain would linger o'er the light side of Nature, and enjoy the marvellous beauty of the great transformation ere turning to sterner things, which may have to be faced in the near future, when to tender springing growth and bursting blossom may come the crisis of a cruel May night before the month on which we have just entered is over. Things which may or may not come, but of which a decade gives sufficient data to enjoin the wisdom of being prepared. Hoping for the best; prepared for the worst.

What a fickle jade our April is! so expressively re-named Germinal—the budding month—when the fever-heat of a revolution preyed on the vitals of La Belle France. Bridal wreaths of Blackthorn made a brave show whilst the month was young and coy, and here and there by the river's brim numberless knots on the Willows swelled until they burst into a charming, pale yellow inflorescence, the "Palm" of childhood's days. Broad patches of Anemone fulgens in military splendour bore the breeze of blustering March, and I know of no hardy flower adapting itself so well to the decoration of heated rooms. Our cottagers cultivate them on the sunny slopes, and they are pulled, not cut, for the market, realising, probably, better prices than any other hardy spring flower, not excepting Daffodils. Ill adapting themselves to the ordinary vases, they are charming nestled in bowls of fresh damp moss.

All the big and little trumpets of the great Daffodil family have blown, the sturdy broad-leaved bicolor maximus concluding the concert so far as the trumpets are concerned. Laggard poeticus, sweet and chaste, will not be lured from its late habits, and is the most impatient of the

No. 2588.—VOL. XCVIII., OLD SERIES.

tribe of anything in the nature of forcing. But Primroses—"Oh, they are too common to talk about." Common, I grant you, but is it generally known how charming they are transplanted, making a line or patch of them in some cool, shady part of the kitchen garden? "Kitchen garden and Primroses! Potatoes are more practical." Certainly; and Sutton's Abundance is beyond compare, even so late in the season, with any other variety of the "noble tuber" we have tried, too many of which in our stiff soil have been found wanting. Our cook finds them hard to boil, or soft, rather, coming away in flaky shreds ere the process is complete; so their character has been studied, to the end that they are now parboiled in their jackets, after removing which they are roasted or toasted, which you will, to a light brown, making quite a feature in Potato cookery.

Our cook has never been short of a "Cauliflower," or rather Broccoli, the winter through. The latter name she repudiates—"whatever difference there is they are both alike;" we nearly agree with her. All the members of the Brassica family have been abundant, if a little sportive in character. Ellam's Early Spring Cabbage has been to the fore. A few days since we passed a dozen loads of this good-hearted little friend destined for Glasgow. Last year's crop of the Jerusalem Artichoke was exceedingly good, resulting in a little disappointment to market growers anent prices. We cannot say that the market was glutted with them, but the demand a few years since led some to infer that here there was an opening in a comparatively new direction. Our neighbour now says, "'Chokes don't pay." The high character awarded to Royal Sovereign Strawberry for forcing purposes has been more than maintained. One of the best examples of Strawberry forcing ever met with was that lately seen of a number of this variety in 5-inch pots, it being also remarked that the plants invariably consisted of single crowns, hence the reason, probably, of such unqualified success with a comparatively limited root space. The thanks of all growers are undoubtedly due to the raiser of this fine variety.

One has been a little exercised as to whether this is an early or late season; but after halting between two opinions the balance now turns in favour of earliness, for April the capricious left us wreathed in warm-tinted Apple blossom, striking a deeper note in the galaxy of the white of Pear and Plum and Cherry. Through the woods tower up huge bouquets of the wild Cherry, so beautiful, so fleeting. How profusely and persistently the Cherries flower each year, particularly the wild one, which has no heavy tax of fruit to sap its energies.

Lately, in a neighbouring garden, attention was called to a novelty in Nectarine culture. This was a tree of Elruge, planted in a late house on the back wall, half of the branches having been carried through the partition into an early house on which the fruit was stoning, whilst in the cold division the branches were in blossom. The early portion gives ripe fruit early in June, the remainder being deferred till August. All the fruit from this tree was understood to be of high quality; but a little discussion on the matter still left it, so far as root action was concerned, involved in mystery. A long unheated Peach range flowering in March met with hard times, 10° to 12° degrees of frost being registered outside on several nights. Inside the thermometer went below freezing point concurrently; but a good set is now happily in evidence. A dry atmosphere possibly counteracted the malignant influence, and possibly, too, points a moral in the utility of a little protection for outside trees to prevent the night dews from settling on the blossom.

How glorious is now the Italian garden with the flowers of spring! Lines and groups of *Aubrietia deltoidea*, *A. d. grandiflora*, and *A. Leichtlini* are the most imposing tints imaginable among masses of *Alyssum saxatile* and beds of the best Wallflowers. Primrose Dame, Eastern Queen, Veitch's Selected Yellow leave nothing to be desired so far as those varieties are concerned; but a brighter red Wallflower than anything yet obtained is most desirable. In the shrubberies Persian Lilacs are fast opening; but the fragrant old type, called by our cottagers "Old-fashioned Laylocks," we have still a weakness for. The month passes with all things bursting into life and beauty. Small wonder that the absent poet pined for his native land; but there is, withal, that spice of danger which gives a piquancy to its charms.—INVICTA.

DIPLADENIAS AND THEIR CULTURE.

THE genus *Dipladenia* comprises several species and a large number of varieties, the latter superseding the former by their larger, more highly coloured, and showier flowers. All are so-called stove evergreen twining plants, very ornamental, with flowers ranging from white to pink, and from rose to rosy purple. Few stove twiners are more deserving of general cultivation, as the large flowers of some of the species and hybrids are unrivalled for gorgeous colour, and when in flower must be regarded as amongst the most beautiful of stove plants.

Dipladenias, however, are not by any means commonly cultivated in stoves, but rather specially grown for exhibition purposes, the plants having an ill repute as being liable to attacks of insect pests, such as mealy bug and scale, and in not a few cases they are anything but free in growth. This usually arises from the plants not having sufficient light and heat for their sturdy growth and free, floriferous development. Indeed, they can hardly be considered suitable for ordinary stove treatment and training to rafter wires, as this implies too much shade and too great distance from the glass. Besides, *Dipladenias* are of moderate growth, attaining to a height of 10 feet or thereabouts, hence very suitable for comparatively small houses; and in narrow borders along the front of a lean-to or three-quarter span-roof, preferably over the hot water pipes, attain great perfection. The growths can be trained to roof wires in such cases similar to Vines, but as near the glass as may be without the leaves touching.

Propagation is generally effected by cuttings of the young shoots when the plants commence new growths in the spring, these being taken off close to the branch, made smooth, and inserted in small pots in a compost of equal parts crystal sand and peat, covered with a bell-glass, and placed in brisk bottom heat. Single eyes are also taken, similar to Vine buds, and inserted just beneath the soil in small pots, plunging in bottom heat. I consider the former preferable. Roots in either case will soon be emitted, the eyes pushing shoots and the cuttings commencing growth. They can, if several are placed in a pot, be potted singly, doing this carefully when rooted and returning to the hotbed, keeping them close till re-established. When the young plants have well hold of the soil gradually inure to the air of the house, and grow in ample light, heat, and moisture.

If plants are intended for planting out train to an upright stick until the required stem has been secured, keeping side-growths in close subjection, and when sufficiently advanced plant out. Plants for trellis-training also should be grown without stopping, supporting by a stake until of sufficient size to be placed on the trellis. Give larger pots as necessary; but let the pots be full of roots, without very tightly binding before moving. Late shifting of young plants cannot be advised, as even these are better for a rest in winter.

PLANTING OUT.

I must confess to entire failure with these plants in the ordinary side borders of a stove and training the growths to the rafter wires. The border may have been too large, too shaded, and too wet; the plants did not thrive. In a narrow border over the hot-water pipes, and the growths trained to wires affixed lengthwise of the house to the under side of the rafters, they did splendidly. Over the path the flowers are seen to great advantage, and for cutting in trayfuls are simply unique. No table makes such a sensation as one of *Dipladenias*. The gorgeous flowers tell a tale of unsurpassed brilliancy. Sprays look best; and though that may be extravagant, it pays at times to make a great effort and bring "down the house."

The plants like bottom heat—the warmth from hot-water pipes. They must also have thorough drainage, for no plants sooner go wrong when the soil gets and remains wet. Too much soil and too much water usually bring disaster. Good rough, fibrous, sandy peat, with some "nuts" of charcoal and crystal sand in about equal parts (this mixture constituting about one-sixth of the soil) suits *Dipladenias*. I have tried additions of leaf mould, old cow manure, and turfy loam, but the peat régime best favoured the growth of the plants. A space of border 2 feet square and as much deep, 9 inches of this being drainage, will grow a large plant.

GROWING IN POTS.

The young plants for trellises should be grown without stopping, supporting by a stake until of sufficient size to be placed on the trellis. This is best made of small galvanised wire, and in a conical or globular form. If balloon ought to be painted green, as some galvanised wire kills the shoots, or at least injures them when new. When oxidised or old the wire appears not to do any harm. The plants like a little bottom heat. They root better after the potting, which should be done in the spring; and young plants may be given a shift later, but not after July. The same soil answers for pots as for borders—namely, fibrous peat broken up roughly for use, adding sufficient sand to keep the soil open. Some charcoal also is an advantage, and about a pound of basic slag phosphate to a bushel of

the peat proves advantageous, and, besides many other substances, gives phosphoric acid for promoting floriferousness, as well as iron, for colour.

The potted plants cannot have too much light. It is better to put some pegs in the pot and some nails in the rafter and sashbars, and strain some twine between the two points, training the growths to them instead of securing these to the trellis. The light then shines right into the plant, and draws the flowers from the axils of the leaves or the terminals of the growths in due course. Get these, and then it is easy to tie them to the trellis, as the string draws away easily, so as to cover it with flowering shoots as well at the lower as upper part. If the shoots are tied to the trellis there will be little growth at the base, and too much at the upper part. Better still train the shoots near the glass, and when coming into flower loosen and secure to the trellis.—G. ABBEY.

(To be concluded.)

NARCISSUS WILL SCARLET.

THIS is undoubtedly one of the handsomest Narcissus that has ever been shown, and the Rev. G. H. Engleheart is to be congratulated on its production. The crown measures upwards of an inch in diameter, is deep saucer shaped, and of a particularly rich red colour. Not only has it these good points, but it is of exceptional substance. The perianth segments are creamy white. The plant, we were informed, is an excellent grower, and produces foliage of great breadth and strength. The Narcissus Committee, at the Drill Hall on the 26th ult., gave a first-class certificate to Will Scarlet, of which we present a woodcut (fig. 73). The crown or cup ought to have been depicted as slightly deeper.

NARCISSUS AJAX HODSOCK'S PRIDE.

MR. MALLENDER has very kindly given me an opportunity of seeing this fine bicolor Daffodil, a seedling raised by him at Hodsock Priory, Worksop. It is a bold flower with very large trumpet, with open mouth. The trumpet is clear yellow, and the perianth is sulphur white. The margin of the trumpet is very distinctly serrated and lobed. A sister flower to Hodsock's Pride was also sent; but this is much inferior, although the long trumpet gives it some character. A seedling incomparabilis with a deep orange crown, which should look bright in a mass, was also sent. It is said to be a free bloomer.—S. ARNOTT.

PROFITABLE FRUIT GROWING.

(Continued from page 365.)

WE will now revert to the Vines, which were grown along with the Tomatoes in the house I have previously described. Eyes of Black Hamburgh, Alicante, Cooper's Black, Alnwick Seedling, and Madresfield Court were inserted in 3-inch pots about the middle of February, and brought on in the little forcing house already mentioned. As soon as the pots were filled with roots they were transferred to 5-inch pots. The soil used was from a part of the field where the turf had been taken off, and nothing was added to it. As soon as they were established in the 5-inch pots they were placed amongst the Tomatoes, and though a cold summer, with no fire heat and constant top ventilation, they grew well, and were nice little canes about 4 feet high, with a perfect potful of healthy active roots by August 1st, by which time they were planted in their permanent places on the west side of the span, close to the front. The method of planting was to turn them out of their pots and without loosening the roots in any way, setting them on the border—not in it—5 feet apart. A pailful of fresh soil was put round each ball and made firm with the hand; this left them in little mounds like molehills. They made capital canes that autumn, and got fairly established in the soil. When possible all Vines should be planted when growing, and not out of larger pots than 5 or 6 inches. The following winter they were cut down to 18 inches from the ground.

In spring the borders were thoroughly dug, and as the soil was now deeper and richer, Ham Green Favourite Tomato was planted. The object this year was to have the Tomatoes earlier, and well established and fruiting before the Vines robbed them of any light by their foliage. So they were kept a little warmer than in the previous year—but in no sense forced—to keep the Vines back as long as possible. A hole was bored in the wood which formed the side of the house—opposite each cane—and the points pushed through to the outside, all eyes left inside being removed. They were kept in this position as long as possible, and when taken in they were soon started. One leader was taken up from each, which by autumn was a medium-sized, short-jointed, well-ripened cane—going up one side of the span and down the other, or about 20 feet. A full, good crop of Tomatoes was got from the house this, the second year. The following year the east

side of the house was again planted with Tomatoes, but only one row, and that next the path on the side the Vines were on. Most of the Vines were strong enough this year to have carried a few bunches, but as the object was not to see how soon Grapes could be had, but how to take most out of the house, they were cut back to the bottom Vine, and two leaders instead of one taken up from each. They made very fine canes this year, and were again allowed to grow down the other span. The Tomato crop was not so good this year, as the Vines from June onwards monopolised most of the roof space.

This was the third and last crop of Tomatoes grown in the house, other things being substituted which agreed with shade. From 4 to 5 feet of wood was left for the first crop of Grapes, the next and third year since raising. An average of four bunches was left on each rod, or eight to a Vine of from 2 to 5 lbs. weight. The Madresfields averaged $2\frac{3}{4}$ lbs. with very large berries, not one of which cracked. Though some bunches lost a few berries through being left too tight, the tender skin of this variety going where it was most squeezed, all finished fit for an exhibition table. Many of the Alicante bunches brought from 10s. to 15s. per bunch. These were seen in a shop window by one of the best Grape growers in Ayrshire, and declared the finest Alicantes he had seen. The weight of fruit per foot run on this variety was over

FIG. 73.—NARCISSUS WILL SCARLET.

3 lbs., and they have carried and finished perfectly nearly as much weight per foot for five successive years, and are as strong and vigorous to-day as ever. I may state, however, that this variety has been allowed to extend, occupying each year a larger space, and now fill the other side of the span and going through to fill a similar house built alongside. The bunches in the Alnwick Seedling were the first year much smaller than the others. No difficulty was experienced with the setting of this variety, either in the first or any year since.

I will now state what was done to the borders. The inside one received a few dressings of Thomson's manure annually, and a good mulching of manure just before the Vines broke into leaf, and a few times has had some inches of fresh soil added to raise the border to the level of the mounds where the Vines were planted; and once this mulch was covered over with fresh soil similar to the plan adopted with the first Tomato crop. The roots from the first were encouraged to enter the outside border, which was kept well dressed with manure during the summer. What was left of this mulching the following spring was covered over with a few inches of soil and again top-dressed. This was annually repeated until the border was about twice its original depth. Dressings of Thomson's manure were also given outside, and heavy waterings in a dry summer.

I have endeavoured to place before you as plainly as I can the details of a system of culture by which heavy crops of the finest Grapes and Tomatoes were produced with little or no expense at border making, where not so much as one spadeful of the orthodox turf was at any time used, in a cold bleak locality, 300 feet above sea level, from ordinary farm land, the average value per acre paid by surrounding farmers for such being about £1.

I have now something to say about giving air to a vinery. I do not expect you will all agree with me here, but that may be the

means of your thinking the matter out for yourselves, and testing by practice the soundness of—I was going to say my theory—but it is not theory but sound practice I am to advocate.

The system that has been handed down to us from our forefathers of admitting fresh air to the occupants of a hothouse, by opening both top and front ventilators, is, in my opinion, to use an old Scotch saying, "wrang, far wrang, and a' th' gither wrang." Not only is front ventilation not necessary for Vines, but it is positively injurious. Nay, I will go further, and say that for almost every plant that is usually grown under glass, front or side ventilation is unnecessary, and in many cases injurious. If a strong healthy man were obliged to sit for so many hours each day between two open doors, what would be the result? If a weakly man, who had been coddled in heat all his days did the same, would the result not be more disastrous? So with a house of Vines, which are often too much coddled and stewed. Are they not sitting or growing in the draught of two open ventilators? How can you expect weakly thin foliage to withstand the attack of insect pests when the strong under similar circumstances suffer? I believe that in ninety-nine cases out of a hundred you could trace every attack of red spider on Vines to faulty ventilation. If you take the trouble to watch you will see it begin close to a ventilator, or where a direct draught is blowing. I assume, of course, that no plants affected with spider are in the house. Take the case of the foliage of the Gros Colnau Vine. This variety, though a robust grower with a good constitution, has peculiarly tender leaves, which are oftener seen during the growing season cupped up at the edges and quite brown. The popular belief is that this is caused by the strength of the sun's heat, and obscuring the glass is recommended as a remedy. Well, I have painted the glass more than once over the leaves, but never could say that it did any good; but I have seen Vines of this variety entirely cured by the discontinuance of front ventilation, and keep their leaves as flat and green to the end of the season as any other variety.

Great care and judgment are required in giving air, and though I advocate abundance of fresh air, especially for black Grapes, it should only be admitted from the top.

You need not be afraid of scorching. Vines will stand a high temperature without injury. I once saw a house of early Hamburgs, a lean-to facing south, grown without once opening a ventilator until the Grapes were colouring in May, and not a scorched leaf. I have also seen every kind of fruit, from a Pine Apple to a Strawberry, and every kind of plant usually grown under glass, stove, and greenhouse, flowering and foliage, Ferns and Orchids, grown, and grown successfully, without the use of front ventilation. It is not necessary. We never use it in any house, and we have 40,000 square feet of glass.—D. BUCHANAN.

(To be continued.)

A BRITON IN BELGIUM.

ONE of the many things which strike even a casual student of human nature is that in spite of the fact that most people express an unbounded contempt for every country except the one which has had the privilege of producing them, they nevertheless assume new airs of importance when they return from abroad. Of course this is not so marked in the case of gardeners as in that of common humanity. Gardeners are above ordinary weaknesses of the flesh, and are a select and superior race. But being in the main observant men, not without an eye to the humorous foibles of their fellow countrymen, they must have remarked the inconsistency which I have pointed out.

It is a long time since the first Briton went abroad and returned bursting with fresh importance. It will be a long time before the last one does. When the New Zealander stands on London Bridge surveying the remnants of a fallen empire, he will be accosted by an odd member of the vanished race, just in by the Harwich boat and garrulous about the Ghent Azaleas. Should the disgusted New Zealander disclaim any interest in the Ghent Azaleas, then the returned native will describe the newest Aroid, or his last plate of Witloof. Subsequent events are a matter of conjecture. With all respect to Macaulay, I am of opinion that the Antipodean will retire vanquished from the field, leaving the horticultural Saxon in the full flow of an harangue on the subject of plant grouping, or the superior flavour of Antwerp Radishes over the produce of Little Mudbury.

It is not certain that this peculiarity of the travelled Briton is an unmixed evil. On the contrary, it is quite likely to exercise a beneficial effect. From the biggest bore often falls the most valuable hint. By a comparison of methods the way to improvement is often found. Therefore, although you or I, or the other man, may be regarded as a bit of a nuisance in airing views that are perhaps stale,

a chance observation of practical value serves to redeem a reputation. Would British gardening be what it is if our incessant palavers and scribblings had never been? It is more than doubtful. Perish the thought, therefore, that any apology is needed for a few random jottings, whatever the terrible cynic may say who argues that discussions and papers and articles—everything, in fact, except plain shovelling—are waste of breath, paper, and time. I know he has condemned me beforehand, but I must try and eke out a miserable existence notwithstanding.

Liverpool Street, London, at 8.30 P.M.; Harwich at 10; Antwerp at 9 the next morning—an easy programme of swift train, comfortable steamer, and light charges. There is not a great deal of horticultural interest along the lower reaches of the Scheldt, but the man who varies his gardening reading with history finds other things to attract his attention as the steamer pursues its winding way. There is the spot, for instance, where a band of Alva's soldiery—magnificently brave if magnificently cruel—forced their way through ten miles of mud and water in gloom and fog; rarely in less than 3 feet of water, often with its chilly fingers creeping round their infamous throats, to emerge triumphantly from their terrible ordeal and surprise a Flemish garrison. Motley tells this story, with many another of thrilling interest, in his monumental work, "The Rise of the Dutch Republic." It is not peaceful horticulture—very much the contrary, but it is vivid and absorbing enough to keep the most ardent gardener from his favourite journal far on into the midnight hours. And the end of it will be a deeper thankfulness for the blessings of peace and freedom—a mingling of horror and relief; of terror and admiration; of breathless, awe-stricken loathing for the black records of the past, and of joy for the calm prosperity of the present.

If the horticultural visitor, once off the beaten track of his own particular pursuit, cares to linger for an hour or two amongst the antiquities of Antwerp he may be sure of a rich reward. The Plantin Museum alone will beguile ample leisure. Never say that it has no interest for the gardener; it is full to overflowing. For three centuries Plantin's was one of the most famous printing houses of the world. It produced books of all kinds, from illuminated volumes the cost of which ran to hundreds of pounds each to (no doubt) handbills extolling the merits of the sausages sold by the dealer round the corner. It printed books of botany amongst others, and in its cases are the old woodcuts prepared by engravers long since passed to their rest. So admirable was the work that the plants are recognisable at a glance, and to all appearances the blocks would print perfectly well to-day. A guide who, after several unavailing attempts, had fastened on to me, gave me amazing descriptions of these engravings. As, however, I perceived that he had mixed up a botanical with an astronomical work I excused his confusion of *Lilium candidum* with the Milky Way.

There is a wonderful old Vine on the wall of the picturesque quadrangle said to have been put in by the first printer, Christopher Plantin, more than 300 years ago. Perhaps it was, and if the report is true it is certainly one of the world's famous Vines. True, the reproach may be levelled at it that it has not been grown on the express system; but gardeners of the old school will make all allowances for that. Doubtless if Plantin had been as well instructed in horticulture as he clearly had been in printing he would have brought such astonishing skill to bear upon it that it would have been dead generations ago. My guide, who was about thirty years of age, endeavoured to foist a story upon me that he had been familiar with the Vine since its tenderest years. I thereupon took up with an official one, who produced a poem, sold it to me for a franc and a half, and then abandoned me. The poem, like the Vine, was by Plantin. It set forth the old printer's idea of happiness in this world, and as amongst the items enumerated were a sweet garden, a limited supply of children, and a quiet wife, Christopher must be held in respect as a man of wisdom, judgment, and discrimination. He left a family, though.

The more the visitor sees of this wonderful museum, the more pleased he is that he did not pass it by because it did not happen to be a plant nursery. It is a nursery in a way—a nursery of fruitful thought. The passer-by finds himself back in an old world, the gardens of which were filled with aromatic plants and herbs of marvellous properties. He thinks, as his eye wanders over flower paintings, flower designs for priceless illuminated volumes, and flower engravings for scientific works, of the sedate gardeners of the past centuries. They did not grow Azaleas as he is presently to see them at Ghent; they did not cultivate *Odontoglossums* as he has already seen them at the Temple. Their spring-sown Onions were not of the size of Alva's cannon balls, nor were their Grapes what are shown at Shrewsbury; but—and a big, eloquent, noble but it is—they laid the foundation by their unwearied patience, careful observation, and ever-

burning zeal, for the triumphs their children's children were to see; they made possible the great and inspiring art which horticulture now is.

It would be an inconsiderate act to drag readers, without a particle of interest for thumbscrews or paintings, to Antwerp's other great sights—the Steen Museum and the Picture Gallery. I can only say that, wonderful works of art though many of the pictures are, I found the thumbscrews rather less harrowing; but from both of these terrible records of a stormy past it is a relief to escape, for they exercise a hideous thralldom on the imagination. At the gates of the great museum lie the boulevards and avenues of modern Antwerp—tree lined, as every town street should be; bright, fresh, and cheerful. Perhaps if we could begin our great towns all over again, we might build them so as to admit of at least a modicum of light and air; as it is, we can but envy the continental his broad, airy, leafy promenades, and sigh for the unattainable. Yet an inconsistency insists on presenting itself. British horticulture claims, not without justification, to set a pattern to the world, but it fails completely to lay hold of the consciences of our town councillors and shame them into better ways; so that, even with the new building which is going on, we are perpetuating the bad old system of narrow streets, packed houses, and box-room gardens. There is a simple economic explanation of it all. The continental loves to put his savings into land, the Briton into bricks and mortar. There is no getting over the fact, or the results that spring from it. If you and I had a lot of bricks and mortar, our indignation at the sight of treeless streets would soon go off the boil.

So pleasant are the broad and leafy avenues of New Antwerp that there is less eagerness than is the case in British towns to get away to the suburbs and environs. It is done sooner or later, perhaps, but generally later. Immediately, however, the visitor passes through any of the numerous city gates and past the fortifications into the open country he finds himself in a new field of interest. To begin with, there is a study in peasant proprietorship ready to his eye. Scores of acres around Antwerp, as around so many continental cities, are market cropped, and nearly every acre has its owner. Are they prosperous, these thousands of small landed proprietors? Monarchs of all they survey, must it be said of them, as of the monarch race in general, "uneasy lies the head which wears a crown?" These are fateful questions, for on the answers to them hangs the issue of our own problem of rural industry. I gladly escape the responsibility of treading dangerously on political ground by disclaiming ability, in the short time I had for study, to give an adequate reply. But certain points infallibly come home to the observer.

To begin with, it is food for speculation whether Belgian cottage homes are the more comfortable, cheerful, and cleanly from the fact that all the family seem to spend the day in the fields. With Hop gardens around my own door, I am aware that women and child labour is drawn upon, especially in harvest time. Indeed, women and child pickers are more expert than men. But our Kentish folk manage to get a very fair living without the necessity for the lady of the house to wield a digging fork and her eldest daughter to carry the manure. A typical family scene in Belgium comes before my eyes. The head is digging, his wife is digging. A sturdy son, age about seventeen, wields a Potato planter; a girl a year or two younger is pulling some dark, rank-looking manure into shreds and putting it in the holes. A juvenile a stage younger is dropping the Potatoes; he looks moderately cheerful, but has tender reminiscences of marbles. A younger scion still is kicking soil over the sets. If he were mine I should speedily kick him, but he is in the rear, and is left to pursue his own peculiar method of covering undisturbed. Naturally, a breadth is soon planted, and I hope the returns are enough to give the busy family plenty of good food and clothing through the winter, which must press hardly on them. If it does not, with all this family labour, then is peasant proprietorship more beautiful in the theory than the practice.

The workers are pretty thorough in their manipulation of the soil. Some of them at least are believers in spring trenching. Most of the cultivation is with hand tools, and the land is worked two spits deep. Moreover, it is heavily fed. An astonishing quantity of both solid and liquid manure is applied, the Belgians being apparently of opinion that they can make better use of their sewage than to pollute rivers with it. No doubt they receive much sympathy in Great Britain regarding this singular delusion. Not from every Briton, though. To individualise, not from Mr. H. J. Jones. The Chrysanthemum King (which is the genial one's Belgian title) boarded my train at Ghent, and fell to telling me of his misguided faith in what other people cheerfully throw away. Every time his eye (which is rather a wideawake one too) fell on people ladling mysterious liquids out of tubs, he irradiated things with an approving smile. What that smile is I need not say. But its effect on the different family parties was marked. Even the boy who wanted to be at marbles felt it, and lost his gloom.—W. PEA.

(To be continued.)

WEATHER IN LONDON.—A portion of the shortage of rain, of which so much has been said of late, must have been made up during the past few days. On Thursday, Friday, and Saturday of last week there were occasional heavy showers, with gleams of sunshine and high wind on the latter day. On Sunday we had a downpour throughout the day, which cannot but have done good. Monday was bright and warm until the afternoon, when a light shower fell. Tuesday was a genial day, while at the time of going to press on Wednesday it was warm, and a slight drizzle was falling.

— WEATHER IN THE NORTH.—A great deal of rain has fallen during the past week, the nights of the 28th and the 30th ult. being especially wet, and on but few days was there much sunshine, while cold E. winds have made the evenings occasionally chilly. May opened with a lovely day, but the afternoon became dull and colder. There was again heavy rain on Monday night, and Tuesday morning was drizzly with coldish wind from the east. Heavy floods are reported from the eastern counties.—B. D., S. Perthshire.

— ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, May 10th, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. At three o'clock the Rev. Prof. G. Henslow, M.A., V.M.H., will lecture on "Some of the Plants Exhibited." The schedule of the show of British Grown Fruit, to be held at the Crystal Palace on Sept. 29th, 30th, October 1st, is now ready, and can be obtained on application to the Secretary, R.H.S., 117, Victoria Street, S.W.

— ROYAL HORTICULTURAL SOCIETY.—SCIENTIFIC COMMITTEE.—April 26th. Present: Dr. M. T. Masters (in the chair); Prof. Müller, Rev. W. Wilks, and the Rev. Prof. Henslow, Hon. Sec. *Vine Leaves with Gummy Exudation*.—Some leaves were received from Mr. F. M. Gulrin, Iscoed, remarkable for a stickiness. This appeared to be attributable to green fly, although none was present. The exudation is the result of puncture. *Pæonies, Decayed*.—Mr. F. F. Freeman sent some leaves which appeared to have decayed at the junction with the stem. They were forwarded to Mr. W. G. Smith for examination for the presence of fungi. *Ribes coccinea, Growth of*.—Mr. Henslow described a rather curious case of a bush growing by the south side of some palings. It had sent up a number of shoots on the north side. The former half were in full leaf bearing very few racemes; while that on the other side was covered with flowers, the foliage being scarcely apparent.

— PRUNUS NANA.—A bed of this species in flower near the temperate house at Kew comes in for a good share of well-deserved admiration by all who see it. In general appearance the leaves and flowers resemble those of the Peach or Almond to a certain degree, though smaller. It is of dwarf habit, old plants not being more than 3½ feet high. The flowers are three-quarters of an inch across, bright pink, and produced from almost every bud on last year's wood. For a bed on the outskirts of a lawn, as at Kew, or other prominent position this species has several recommendations, being of neat habit as well as a good flowerer. For forcing during early spring for the greenhouse it is also an excellent plant. Cuttings do not root readily, but by layering a plant or two a stock can soon be secured.—W. D.

— GOOD EARLY CABBAGES.—When looking at some superb Gloxinias which Mr. Young, gardener to Mrs. Pearson, Kingston Hill, has in one of his small houses, he said, "Before you go, come and see my Cabbages." Well, it did seem to be a big drop from Gloxinias to such humble vegetables, but I could not otherwise than admire the true inwardness of the gardener who was equally enthusiastic over Cabbages and flowers. I went to the kitchen garden, and saw his Flower of Spring, Ellam's Early, and Maincrop. The breadth was indeed a capital one, and I observed that although all had been sown and planted at the same time, Flower of Spring was earliest. Mr. Young said that some of his fellow gardeners were surprised to find he has been cutting such good heads for some time. That is doubtless because they still stick to old late large varieties. The wonder now is that anyone should grow them. Once it was thought good to have Cabbages turning-in at Whitsuntide; now we expect to have them in abundance at Easter.—WANDERER.

— **DEATH OF MR. A. W. BLICK.**—We learn with regret of the death of Mr. A. W. Blick, who will be remembered as taking a keen interest in horticultural matters, and who was for about twenty-five years intimately connected with the Royal Horticultural Society. The deceased passed away at Brentford on Monday, May 2nd, at the ripe age of seventy-one years.

— **PELARGONIUMS FOR WINTER FLOWERING.**—Valuable as are Zonal Pelargoniums for winter flowering, it is comparatively seldom that one sees a really first-class collection. This is regrettable, and we trust that Mr. C. H. Parker's endeavour to popularise them will be well rewarded. On page 390 we give in abridged form a paper read by Mr. Parker, who is an ardent amateur horticulturist, at a recent meeting of the Barnsley Paxton Society, and we commend the information therein to the notice of our readers.

— **STEEPING SEEDS IN WATER.**—Some persons soak Kidney Bean, Beet, and other seeds in water previous to sowing, but the practice is not to be recommended, especially at this early period, when the ground is not yet thoroughly warmed. There is usually enough moisture in the soil for the needs of the seeds, though it may not be very apparent. The moisture required is mainly absorbed in the form of watery vapour, and the warmth of the sun acting upon the surface soil will cause sufficient for the demands of the seeds.—E. D. S.

— **PRIMROSES CHANGING COLOUR.**—Can anyone tell me the reason of the common Primrose changing colour. I planted three years ago a clump of wild Primroses taken from a wood. The first year they came yellow, the second year there were two or three blossoms among the yellow ones of a dark colour. This year they have come all dark, and with only two or three of the original yellow colour in the centre of the clump. The foliage remains green, as when in the wood or when first planted. There are no coloured Primroses in the garden.—H. S.

— **A STUDY IN CUCUMBERS.**—It is a matter of education as well as of interest to walk through the Cucumber houses at Rowledge when Mr. Mortimer has his trials on, and is also growing large stocks for seed production. We then have such an admirable opportunity to become familiar with the character of the fruits of most of the leading varieties in cultivation. Thus there is the now well known Lockie's Perfection, but which under careful yearly selection has there grown from 12 to some 16 inches, and is a first-rate stock. Telegraph Improved, or otherwise, is yet an excellent variety as a cropper, but it wants deeper colour, and to be rid of the long heel or handle which characterises it. Rochford's Market, now the best spine Cucumber in cultivation, is readily recognised, and so, too, are Sutton's Progress, Success, A1, and others. In spite of the existence of the greatly improved varieties named, some houses still cling to old ones, and I learned that Cuthell's Black Spine was in particular request. Some new varieties are being grown also, as with all the advance made the ideal market Cucumber does not seem to have been obtained. So far Telegraph and Rochford's hold the field.—A. D.

— **THE POPULARITY OF THE DAFFODIL.**—The notes on "Daffodil Land," page 353, remind one that what the pioneers in the culture of the nodding flower have commenced, general lovers of the family are carrying on with vigour. Perhaps no flower has increased more rapidly in popularity, and among enthusiastic amateurs there appears to be a general desire to become possessors of the novelties as they come out. Probably this accounts for the fancy prices which "Daff" quotes in his notes. Things were different a few years ago when, with the exception of several enthusiasts, the only Daffodils found in private gardens were the Lent Lilies, and later on the Poet's Narciss. Lately it has been my privilege to visit gardens of no great pretensions, and in several of them I have been struck with the varied and interesting collections of this popular flower. One amateur has instituted a Daffodil show in his not very large garden. Last season the first exhibition was held, which he assured me was a great success. This gentleman sends out invitations to his friends and acquaintances when the flowers are at their best, and in return asks for a subscription, which is duly handed over to a local charity. The show does more than help a deserving institution, it encourages the further growth of the flower, for many who see the superb little collection are so charmed with its interesting beauty that they become Daffodil growers themselves. The result is that the flower is grown in many more gardens in the neighbourhood. Working men have also caught the fever, and nowadays it is no uncommon thing to see Sir Watkin, Empress, Golden Spur, and other such favourites nodding their heads in the little front gardens of the artizan class.—G.

— **APRIL WEATHER AT DRIFFIELD.**—Mean temperature at 9 A.M. (corrected), 46.80°. Wet bulb, 44.22°. Mean maximum, 52.68°; mean minimum, 37.54°. Highest, 66.5° on the 8th; lowest, 27.2° on the 1st. Mean of maxima and minima, 45.11°. Mean radiation temperature on the grass, 33.54°; lowest, 22.0° on the 1st. Rainfall, 3.655 inches. Number of rainy days, fourteen; greatest amount on one day, 1.170 on the 11th.—W. E. LOVEL, *Observer, York Road, Driffield.*

— **SUSSEX RAINFALL.**—The total rainfall at Stonehurst, Ardingly, for April was 1.09 inch, being 0.66 below the average. The heaviest fall was 0.23 inch on the 14th. Rain fell on ten days. The maximum temperature was 65° on the 8th; the minimum, 32° on the 5th. Mean maximum, 58.20°; mean minimum, 39.15°; mean temperature, 48.67°, which is 1.31° above the average. The month has been dry, with a good deal of sunshine, and cold northern winds. There has been no frost to hurt fruit bloom, which is very promising. Some welcome showers have fallen since the 26th.—R. I.

— **APRIL WEATHER AT DOWLAIS.**—The total rainfall here for the past month was 3.62 inches, which fell on thirteen days, the greatest fall being 0.65 on the 11th. Average maximum temperature, 58.5°; highest reading, 75° on the 25th; mean minimum, 32.5°; lowest reading, 20° on the 4th; below freezing point on nine days. There were seven sunless days. The wind was in the W. and S.W. on eighteen days, and in the E. and S.E. on ten days. Very stormy, with strong winds in the second week. The last two days were very rough and wet, the wind at times blowing quite a gale.—WM. MABBOTT.

— **THE WEATHER LAST MONTH.**—The wind was in a southerly direction twenty-one days. Total rainfall, 1.89 inch, which fell on thirteen days, and is 0.09 inch above the average for the month; the greatest daily fall was 0.38 inch on the 11th. Barometer (corrected and reduced).—Highest reading, 30.248 inches on the 21st at 9 A.M.; lowest, 29.393 inches on the 11th at 9 P.M. Thermometers.—Highest in the shade, 66° on the 8th; lowest, 23° on the 5th; mean of daily maxima, 54.76°; mean of daily minima, 37.60°. Mean temperature of the month, 46.18°; lowest on the grass, 17° on the 5th; highest in the sun, 128° on the 29th. Mean temperature of the earth at 3 feet, 45°. Total sunshine 161 hours 45 minutes. There were two sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham.*

— **POTATOES FOR IRISH PEASANTS.**—A daily contemporary states that the Local Government Board has addressed a letter to the Guardians of several Unions in the west of Ireland, saying that representations having been made to the effect that many persons employed on the relief works have been unable to avail themselves of the Seed Supply Act this year owing to poverty and the high price of seed, the Government will give a bonus in the shape of a free grant of Potato sets to families whose members, resident on the holdings, were employed on the relief works on or before April 6th. The entire cost of the grant will be borne by the Government, and is to be regarded as an additional recompense for the labour given. All the Unions to which the letter has been addressed have accepted the offer.

— **KEW GARDENS.**—In the course of the discussion in the House of Commons on the vote to complete the sum of £115,000 for the maintenance of the Royal Parks and Pleasure Grounds, Mr. Akers-Douglas said with reference to his decision to open the Gardens at an earlier hour in June next, and the two following months, there never had been a difference of opinion as to opening the Gardens at an earlier hour subject to two conditions—that the Gardens would be taken advantage of by the public; and, secondly, that it would be safe in the interests of science and the students at Kew to grant an extension. It had at length been decided to open on June 1st at 10 A.M., and to open them at that hour every morning for the following three months. If it were found that the public appreciated the new arrangement, and visited the Gardens to the extent that the advocates of the earlier opening of the Gardens said they would, the Office of Works would make the extension of hours—as far as the summer months went—permanent. The Queen's Cottage would be handed over by the Lord Chamberlain's Department to the Office of Works on June 1st, and, as soon after as the Office of Works could make the necessary arrangements, the grounds would be open to the public. It was the intention to preserve the grounds as far as possible in their present condition. They would only open a path from Kew Gardens to the cottage. The rest would remain much in its present condition. It would not be cut up unnecessarily, and it should still form one of the most beautiful bits of wild country in the proximity of London, and be, as it certainly had been, a sanctuary of all bird life in the district.

— **A GENEROUS GIFT.**—A botanic garden is likely to be founded at Aberdeen, for we learn from a correspondent that Miss Cruikshank, sister of the late Dr. Cruikshank, has offered £15,000 to the Aberdeen University for the provision of such a garden in memory of her brother.

— **NARCISSUS AT THE DRILL HALL.**—When making our report of the Daffodils at the Drill Hall, on the 26th ult., we particularly noted the superb collection from the Chilwell Nurseries of Messrs. J. R. Pearson and Sons. Not only were the varieties numerous, but the quality was excellent throughout. By an oversight we omitted to record the fact that a silver Flora medal was given to this exhibit, and we may add that the award was thoroughly deserved.

— **FIRE AT MESSRS. WATKINS & SIMPSON'S.**—At a few minutes after midnight on Thursday a fire broke out in Exeter Street, Strand, which at one time threatened to involve the whole block of buildings between St. Michael's Church, Burleigh Street, and Covent Garden Market. The fire originated in the premises tenanted by Messrs. Watkins & Simpson, in Exeter Street, who carry on a business in seeds and bulbs, the upper part of the premises being used as a storehouse. The fire was noticed by a workman employed at Covent Garden Market, who was passing by at the time, and he immediately gave information to the policeman at Burleigh Street. A fire escape was immediately brought on the scene, and in the meantime news of the outbreak had been telephoned to the various fire stations in the vicinity. In less than five minutes an engine arrived from Whitefriars Street, and quickly got a hydrant to work from Burleigh Street. By a quarter past twelve five steamers and eight branches of hose were sending volumes of water on to the building. By this time the premises were enveloped in a mass of smoke and flame. Shortly afterwards the building of the Ballantyne Press caught fire, but the flames were immediately suppressed. At five minutes to one the fire was got under, but not before three floors of the seed warehouse had been burnt out. During the whole time engines continued to arrive, and altogether over a dozen were on the scene. The building destroyed was one of four storeys with a frontage of about 35 feet. The cause of the outbreak is at present unknown. Arrangements have been made to cause as little interruption to business as possible.—("Westminster Gazette.")

— **CABBAGES SEVEN FEET HIGH.**—A case, Howcroft & Watkins v. Laycock, was tried by Judge Lumley Smith, Q.C., in the Westminster County Court, on Monday, 25th ult., and was a claim by a Covent Garden seed firm against the Rev. G. T. Laycock, of Petersfield, Hants, for £24 1s. 6d. for seeds supplied. The claim was admitted, and there was a counter claim for £18 damages for breach of contract. The case for Mr. Laycock on the counter-claim was that amongst the seeds was a packet of seeds for which 2s. 6d. was charged. He ordered Couve Tronchuda. He had the ground manured, the seedlings transplanted, and they should have grown to about 18 inches high, but they grew on and on until they became 7 feet high. (Laughter). His Honour: A Cabbage 7 feet high? Defendant: Yes; I have 20,000 of these worthless plants. His Honour: Twenty thousand gigantic Cabbages. What are they like? Defendant produced two about 8 feet high. Each of the stumps was about 2 inches in diameter, and was surmounted by a tuft of leaves, and about twenty clusters of yellow blossoms. His Honour: Are you sure they will not grow any higher? Defendant: I have let them go on with the hope of their turning into something useful. (Laughter). Defendant stood the plants by his side, and they stood about 2 feet higher than himself, the flowers hanging down resembling Laburnum. He considered he had sustained £40 damages. Cross-examined as to plaintiffs' "non-guarantee clause" on their invoices and catalogues, defendant said he sent eggs of fancy poultry all over the world, and was of opinion that he had to supply what was ordered, and no clause would exonerate him. For the sake of his reputation he should always take care that customers eventually got what they ordered. Mr. Barron, late of the Royal Horticultural Gardens, Chiswick, said the plants produced were Jersey or cow Cabbages. The stalks were sometimes made into walking sticks. Mr. Eck, plaintiffs' counsel, said it was a Marrow Kale, and, had it been cut five or six months earlier, would have been as palatable as that ordered. His Honour found that the plant ordered was a Cabbage fit for people to eat. The plants produced were not, and though he fixed the damages at £21, plaintiffs were protected by the non-guarantee clause, and there would be judgment for them. Notice of appeal was given by Mr. Laycock. [While seedsmen are justified in protecting themselves against the consequences of failures which may be the result of errors by purchasers or cultivators, the question to be settled is, "How far a vendor's non-guarantee clause shall operate?" This is obviously a matter of far-reaching importance.]

— **CUTTING IVY.**—The present time is one of the best periods for cutting back Ivy on walls and buildings. The bareness resulting from severe cutting-in will not last long, inasmuch as new growth must shortly start, and luxuriant foliage beautify the position.—S.

— **BLACKS IN TOMATOES.**—It is not a very far transition from blacks in Potatoes to blacks in Tomatoes. From my own experience, and that of a neighbouring gardener who grows Tomatoes remarkably well, I am firmly convinced that this spot is first caused by the sun coming on the moist fruit early in the morning before sufficient air is admitted.—N. N.

— **STEAM LAWN MOWERS.**—Will any correspondent using these kindly give their experience as to their capability of working on steep gradients and among trees and shrubs where there is very sharp turning about? We have several acres of such lawn, and at present employ five small 12-inch machines. We have horse machines, but cannot use them, as there is no room to turn, and the ground being mostly on the slope makes it worse. Any answer will be esteemed by—EROMEGNAR.

— **DAHLIAS.**—As so many fine exhibition flowers have been during the past few years produced on what was but a piece of barren hungry heath at Farnham, no one who has poor soil need be discouraged when embarking in Dahlia culture for show. Occasional trenching and liberal manuring help wonderfully to bring even a very poor soil into fine condition. It is that treatment which enables this Farnham heathland to produce first-class show Dahlia blooms. Just now holes are being prepared over nearly an acre of land, each 4 feet apart. Some short manure and old pot soil is added in each case, then when refilled a stout stake is driven into the centre, against which about the end of May the plants are put out. So great is the development of the Cactus section, and so great the variety, for all the best have to be grown, these seem to rival all other sections in area requirements.—D.

— **A MUSHROOM MARTYR.**—A producer of light reading in the "Morning Leader," under the floricultural heading of "Sub Rosa," thus delivered himself the other day:—"I once tried a little gardening—only a little, and only once. I saw a beautiful picture of some Mushrooms in a seed catalogue, and the explanation of how to grow them was so clear and simple that I set to work; and it was work too. First of all I had to make a bed, and though I forget how I did it, I distinctly remember that I felt inclined to lie on it. Some may think I am lying on or about it now—but I'm not. I don't forget, however, that I had to spank the stuff firm with the back of a beastly great spade. I pounded away until at last I broke the spade, and nearly broke my back. I called that spade a spade, and more also; and as to my back, when I tried to stand up I appreciated the truth of Dudley Warner's remark, that the first requisite for gardening is a cast-iron back with a hinge in it. Nothing resulted, though I had obeyed all the instructions of that deceptive handbook till six months or so, when one Mushroom with a blighted appearance struggled through, and I believe it was a toadstool." It seems almost a pity he did not sit on it, for settling its identity: he could but have fallen off. Then he would have had to admit "lying" by its side.

— **EARLY TULIPS AT LONG DITTON.**—What singularly grand coloured masses do these present just now in Messrs. Barr & Sons' grounds when seen from the adjoining railway. Seeing them so distant recently, I was anxious to see them closer, and went over for that purpose on the last day of April—rather a wild stormy day certainly, but in spite of the storms the Tulip flowers were all open, and presenting colouration that can be only fitly described as gorgeous. What a relief to turn from the big masses of the pallid Daffodils to the brilliant and varied hues of the Tulips! How pure and beautiful the whites, of which the old Pottebakker is yet the finest. Then the best yellows seemed to be Ophir d'Or and Chrysolora. Thomas Moore is a perfect Tulip of a rich orange buff colour. Next in hue is Duchesse de Parme, orange red edged yellow, and more effective still is the good old Keizers Kroon, deep red edged yellow. There are lovely rosy tints in Rose Superb, rosy cerise; W. E. Gladstone (new) salmon red self, a perfect flower; another, deeper in hue, is Proserpine, rich ruddy cerise—one of the best. Intense reddish or scarlet crimsons are Crimson King, a very striking bold flower; Joost Van Vondel, brilliant crimson, slightly veined white; Artus, rich crimson scarlet; and Couleur Cardinal, rather late, deep bronzy crimson, and a beautiful variety. Very deep, and a striking form, is Wouverbans, colour rich rosy violet. There are others of this dark hue, but one variety seems sufficient. For those who like delicate tinted flowers none is more charming than Rose Gris de lin and Rosa Mundi, both rose pink. These make a first-class selection. The grand collection of late border Tulips at Long Ditton will be at their best about the middle of May.—WANDERER.

LÆLIO-CATTLEYA THORNTONI.

BIGENERIC hybrids amongst Orchids are now numerous, but the interest in them shows no signs of decrease. On the contrary; when one such as L.-C. Thornton is exhibited it is certain to have a large concourse of admirers. As may be seen from the illustration (fig. 74) the flower bears a general resemblance in form to L.-C. Digbyana-Trianæ, which we figured on September 9th of last year; but at the same time the two are quite distinct. The one now under notice resulted from a cross between L. Digbyana and Cattleya Gaskelliana. The sepals and petals are a soft rosy lilac, and the latter are sharply serrated. The superb lip in which the Lælia parentage is so apparent has a central colour of yellow, paling to white. The broad front lobe is handsomely fringed, and of a rose pink colour. The Orchid Committee of the Royal Horticultural Society awarded Messrs. J. Veitch and Sons, Ltd., who staged the plant, a first-class certificate on April 26th.

ANGULOAS.

THESE are an interesting section of Orchid, very distinct botanically, their nearest affinity being Stanhopeas. The foliage is handsome on well-grown plants, being broad and deep green, springing from dark green bulbs of different size according to the species. The lip presents rather a peculiar structure, being very loosely hinged with the column, and rocking to and fro upon the flower being moved. The plant likes a fairly substantial compost, consisting of equal parts of peat fibre, loam, and chopped sphagnum moss.

The best season for repotting is usually immediately after the flowers are past, but in the case of plants that miss flowering it may be done at rather an earlier stage in the plant's growth—i.e., when considerable progress has been made with the growth, but the roots have not started. It is easy to see whether or not the plants are going to flower in the early stages of growth, as the flowering shoots commence to swell unduly when an inch or two in length, showing the presence of the flower spikes. The practice often followed is to repot after the manner that Calanthes are treated—viz., just as the young growth starts, and in this there is some advantage, though personally I prefer the later season.

I have several reasons for this, the chief being that the young roots will have new sweet material to run in, while when the plants are repotted earlier it becomes more or less saturated with moisture. The strain of flowering, too, is more severely felt by the plants when the roots have just been disturbed. Those who practise potting earlier may say that the young roots are disturbed by the operation, but if carefully done this will be but slight, and is, I think, more than outweighed by the advantages described.

As to manner of potting, it would be well if cultivators would remember that Anguloas have very persistent roots that live more than one season, and for this reason they will not stand being pulled about and shaken completely out, as Calanthes and Thunias are treated. By all means let everything of a sour or close character—or anything that is likely to soon become so—be taken out; but be careful in doing this that the living roots are not disturbed more than is absolutely unpreventable, for much injury is done thereby. It leads to shrivelled pseudo-bulbs and a weakened condition of the plants generally, while it is one of the most important points in their culture that the pseudo-bulbs be strong and stout.

The plants need not be elevated much above the rims of the pots, in fact for healthy well established specimens they are better kept a little below, but badly rooted weak plants may be kept up a trifle with advantage. Drain the pots thoroughly, and if these are of medium size in comparison with that of the plants they will be all the better, as it will not be necessary to disturb the plants again for a couple of seasons. After repotting keep the plants a little on the dry side until the roots are again active, and maintain a moist atmosphere by frequent damping about the stages, pots, and floors.

When rooting freely again keep them moist until the young pseudo-bulbs are finished, when, if the weather is warm, and no frosts

occur at night, they may be stood outside in a partially shaded position for a time. But be very careful that they are screened from direct sunlight, or the foliage will be burnt, and will fall prematurely. It may be noted that the individual plants differ considerably in the time they carry their foliage. Some are quite deciduous, while others will have the older leaves on well into the new year. As a rule the evergreen plants do not flower so freely as those that lose their foliage during the winter.

Scab is often troublesome, but this and red spider are easily kept under if taken in time. The Anguloas are not a large genus, and though many more occur in some lists, there are only about three distinct species. But these vary a good deal, both in size and colour. In A. Clowesi the blossoms are in the type about a couple of inches across, Tulip shaped, or nearly round, and of a clear soft yellow in colour. There is a large flowering variety, A. C. macrantha, also pure white and beautiful form named eburnea, which is often described as a species. It is very rare.

A. Ruckeri is another very variable kind, with large reddish brown flowers, the inner side of the segments yellow, spotted with red. It is a native of Columbia, and was introduced early in the forties, along with the foregoing. One of the finest Anguloas in existence is A. R. sanguinea, a deep blood-red form of the type, while of this, too, there is an albino. A. uniflora is the oldest species known, having been discovered over a hundred years ago in Peru by the founders of the genus, Ruiz and Pavon. It has pretty white flowers, more or less tinged with rosy pink, this colour being the most freely disposed on the petals of the variety Turneri.—H. R. R.

ZONAL PELARGONIUMS FOR WINTER.

IN support of the winter culture of this plant I have this encouraging statement to make at the outset, I do not know a single flower that will continue blooming for three consecutive months in the dark, dreary days of winter, and yield a greater quantity and variety of beautiful flowers at a less cost.

The best and cheapest house is the ordinary span-roofed propagating house running east and west, with abundance of ventilation at the top, a centre path with stages 2 feet 6 inches from the floor and 4½ inches below the wall plate, so that the plants can be as near the glass as possible. Heating is of vital importance, as damp, moist, or cold air will at once cause disaster. In addition to the ordinary 4-inch pipes have a 2-inch pipe about 12 inches above the wall plate. If the stage is made 7 inches deep the plants can be plunged in ashes, while the structure will answer admirably for growing a crop of Tomatoes or Cucumbers in summer time.

PROPAGATION.

The best cuttings are those taken from the half-ripened side shoots from 3 inches to 4 inches long; they are all the better if they have not been allowed to bloom. It is a mistake to attempt to build up a strong healthy plant from a weak, sickly, or sappy cutting. It is a matter of choice whether the cuttings are rooted outside the first week in August or inside during the first week in March; the advantage gained, if autumn rooted, being a larger plant. I, however, prefer spring propagation, as the stock never escapes supervision until the plant is thoroughly developed and ready for outside treatment.

The cuttings should be inserted in earthenware pans, providing good drainage, and shading for a day or two. Keep the leaves moist, but do not wet the soil. When roots have been emitted pot the young plants in large 60's and grow in a temperature of 55° to 60°, using the syringe freely, and gradually giving more air up to the final potting stage. As soon as the plants begin to grow freely pinch into shape and remove all flower buds as soon as they appear.

POTTING AND FEEDING.

Great care must be taken not to damage the new feeding roots when potting, which must be done firmly. The last week in May place the plants in 5-inch pots, using charcoal for crocks. The best manure is made from cow manure and leaf mould in equal parts, using a sprinkling of soot the last time the compost is turned. When ready for use it ought to be in such a condition as will rub through a five-eighth-inch riddle. Make up a compost with one part rich fibrous loam, using as much coarse river sand as will keep it open, and the other part of the above-named manure. Incorporate thoroughly, and let it stand for a few days before using. After the final potting place the plants in a close frame for a fortnight before turning out into the open.

Liquid manures should only be applied when the plants are thoroughly root-bound, and the flower buds forming. I have had very successful results from the following mixture:—Steep 1 bushel of rock culms in 12 gallons of cow urine, mix, and stand for a week; add 6 gallons of soot water and 1 lb. of gypsum, stir well together, and use 1 pint to a gallon of soft water. The gypsum is used as a preservative, and to counteract the caustic effects of the urine; the soot as a general fertiliser; and the rock

culms for the potash. If kept covered up in a tub this liquid will keep good for six months. Chinchas guano in itself makes capital liquid manure. A good liquid manure can be made by dissolving half an ounce of saltpetre and half ounce of phosphate of potash in a gallon of soft water.

OUTSIDE TREATMENT.

Select an airy position fully exposed to the sun, but sheltered from rough winds, and plunge the pots in ashes. Give plenty of room for the sun and air to circulate about the plants, and sprinkle every morning between eight and nine, except in wet weather. The object of this outside treatment is to obtain short, sturdy, well ripened growth, with a correspondingly strong healthy root action, and all the moisture the plants require is sufficient to keep the fibrous feeding roots steadily growing.

BLOOMING PERIOD.

The blooming period is regulated according to the stopping of the bud. D sbud to the first week in October for flowering at Christmas. The plants must have as much light and as dry air as possible, with a minimum temperature of 50° for the singles and 55° for the double and Ivy-leaved varieties. Give the plants liquid manure in proportion to the quantity of bloom they have to support. If flowers are to be packed and sent away it is advisable to drop a small particle of gum into the eye of each one. Never allow a truss to remain on the plant after the centre has fallen.

SELECTION OF VARIETIES.

With such a large number of varieties of almost equal merit, it would be somewhat presumptuous if I attempted to name the best for this

FIG. 74.—LELIO-CATTELEYA THORNTONI.

If early bloom is required allow all flower buds to remain after the end of August. Examine the plants frequently for caterpillars, and as soon as the flower buds are formed the plants may be allowed their first dose of liquid manure. On the approach of frost the plants should be housed. Give as much space as possible between the plants, for it must not be forgotten that beside the charming flowers there is that fine zonal marked foliage, which is so pleasing and so worthy of development.

INSECT PESTS.

The Zonal Pelargonium in a healthy state is practically free from insects. Its chief enemy is the caterpillar, which, being of the same colour as the foliage, requires careful watching during the autumn months. They should be picked off by hand as soon as they appear. Canker is the result of propagating from a bad cutting, or from some unsuitable potting compost. If the foliage changes colour, or black or yellow spots appear, turn the plant out and examine the roots and drainage, replacing in a clean dry pot. The chances are the plant has been waterlogged, and if the roots are not healthy cut back the plant.

purpose. My advice to those who are making up a collection is to visit the plants at some good nursery, instead of trusting to a catalogue description. For the benefit of those who are unable to do this, I have taken the opinions of two of the best raisers we have in this country—viz., Messrs. H. Cannell & Sons, Swanley, Kent, and Messrs. J. R. Pearson and Sons, Chilwell; these two authorities agree that the following are the best in commerce for winter culture:—Souvenir de W. B. Miller, King of Crimsons, Lord Aberdeen, Rev. Brett, Countess of Buckingham, lilacina, Niagara, Snowdrop, Mrs. Pole Routh, Mrs. Hall, Duchess of Marlborough, and delicata. These are single varieties. Of double I recommend Raspail Improved and Hermine, which is white. The best sent out in 1897 (Messrs. Pearson's selection) are Mrs. W. Partridge, Sir H. Irving, Sir J. Kitson, Crabbe, Dryden, Chaucer, Southey, A. Tennyson, and Herrick. The best single Zonal I know for growing all the year round is Cannell's Favourite. The single Zonal which has given me the most satisfaction for winter blooming is Wm. Jacoby, a deep crimson, which will be found classed as a Hybrid Nosegay. Do not forget that good old Zonals are like good old songs, and when you have proved them, stick to them.—C. HY. PARKER.

COLEUS.

DURING the bright days of summer, when the air is warm, the brilliant light shows up the lovely colour shadings of these popular plants to advantage. It has often struck me how different are the appearances of plants when seen under varying conditions of light and shadow. Look at the leaves of a well-coloured Coleus on a dull day; they are even then bright and attractive. But to see their charms displayed to the best advantage bright sunshine is necessary; then the colours appear to be wonderfully intensified, and to sparkle with life and vividness. As decorative plants Coleus are of great value. True they do not last long in rooms, except in the lightest position; but then they are easily and quickly grown, and moreover supply such novel colouring, that they may be regarded as indispensable plants in the majority of gardens.

Various methods of propagation may be adopted with equal success. When close frames in a propagating pit are at disposal cuttings root quickly if plunged in bottom heat, or when inserted in pots or boxes placed on the hot-water pipes of a Cucumber or Melon house root quite as certainly if the soil is kept moist, and when placed in full sunshine on shelves near the glass in a warm moist house roots are quickly emitted, and the young plants kept remarkably sturdy till ready for potting off. This ought to be done as soon as the plants are well rooted. A compost consisting of two parts loam to one of leaf soil, with a little sharp sand added, is one that suits young plants well.

During the summer time I always water the plants thoroughly as soon as potted, and then allow the soil to get fairly dry before water is again applied. After potting the plants should, if possible, be placed on a shelf near the glass, and be stopped as soon as they begin to grow freely, then by the time they are ready for potting they invariably want more head room, and can be placed on a stage in a light position. Those plants intended for decorative purposes should be potted into 5, 6, or 7-inch pots, according to their size, at this stage using a much richer compost; one formed of equal parts loam and hotbed or well decayed manure answers splendidly, as the Coleus is a gross feeder, and will thrive amazingly in a soil far too rich for the majority of plants—in fact, they will grow and colour wonderfully well on a manure heap placed in a warm house.

Plants stopped in a young state as previously directed will send out numbers of young shoots; these, if staked out, or tied to a wire placed under the rim of the pot will form the foundation of a shapely plant. Those in 5-inch pots will require no other stopping, but those potted into 7-inch ones will require the points of the side shoots to be removed once. The above remarks in regard to stopping and tying are applicable to the formation of bush plants, which are generally the most popular. If a few pyramidal-shaped ones are required the plants should be allowed to grow freely without stopping for a time, and be given plenty of room to promote the production of strong side shoots. If the main growth is trained to a straight stake some varieties will branch naturally, and the main shoot will not require stopping until the required height is reached.

I have, however, found it difficult to get some varieties to branch freely without stopping the central shoot; in such cases I pinch when the plant has reached the height of 9 inches, and train up the stronger of the two terminal shoots produced, the other being removed. When large plants are wanted for exhibition purposes, the training in the early stages is exactly the same as that already described, and during subsequent stages, stopping and tying are regularly performed as growth takes place, the former being done for the last time three weeks before the plants are wanted to be at their best, the last tying being performed a fortnight later. For the final potting the soil must be used in a rough state, but should consist of the same ingredients as those recommended for plants in 5 and 6-inch pots. Throughout the period of growth Coleus ought to be given plenty of heat and moisture, and be kept near the glass, no shade being given except when grown in very light houses. Many cultivators object to syringing Coleus, but I consider it decidedly beneficial to do so in bright weather, and I practise what I preach.

To get highly coloured leaves the soil must be packed with roots, the plants well exposed to light, and weak liquid manure be applied two or three times weekly. Before the plants are used either for decoration or exhibition purposes they may be gradually hardened by a freer circulation of air. The following varieties are some of the best in cultivation:—Petit Robert, Countess of Dudley, Beckwith's Gem, Vesuvius, Faith, Elegans, Hermit, Dr. Jackson, Cloth of Gold, Hart's Conqueror, and Arthur Whitley.—PLANTSMAN.

SOWING ASTERS OUTDOORS.—Aster seed sown now in a warm position outdoors will germinate freely. Select a well-prepared friable piece of ground, and draw drills an inch deep and 10 inches apart. Sow the seed thinly and cover with fine soil. Thin out as the plants touch each other, leaving them finally 6 inches asunder, or more if necessary.—E. D. S.

DURATION OF ROSE SHOWS.

I OBSERVE in the list of Rose shows in your issue of April 28th, that at Southampton and Hanley the exhibitions last two days! and at York, Wolverhampton, and Newcastle, they are of three days duration!!

Advancing age is frequently attended with failing memory, so possibly I am incorrect in thinking that many years ago it was resolved by the N.R.S. that Rose shows of more than one day duration should not be recognised, and that on this occasion all the members of the N.R.S. swore by their (Rose) gods that they would abjure two-days shows. May I ask whether this resolution (if there ever were such a resolution) has been rescinded, and, if so, when?

It has never been my misfortune to witness a two-days Rose show, and I trust that I shall never be guilty of a crime of sufficient enormity to condemn me to such a sight. But I have been under the impression that Rose exhibitions were intended by N.R.S. to encourage the cultivation of the queen of flowers in its greatest beauty. I read yesterday that the hippopotamus is extinct, but I presume that there still exists some rosarian who thinks that the taste for a Rose "in its most perfect stage of possible beauty" is enhanced by a two-days Rose show.—HENRY B. BIRON.

SOME OF THE NEWER ROSES.

ALTHOUGH raisers of Roses in France and Germany still continue to pour in a quantity of new varieties, they neither excite the interest that they used formerly to do, nor do they add very much of value to those which we have already had. It was different in former days, when there was always an anxiety to know what Lacharme, or Guillot, or Eugène Verdier and others had to offer us, and we were pretty sure to obtain amongst the mass of indifferent flowers one or two prizes. But now-a-days we miss the names of some of our oldest raisers, and the present generation does not seem to be so successful as that which preceded it.

There are one or two things which strike one in looking at the last list of novelties. We miss in the first place the large number of Hybrid Perpetuals we used to obtain. In the list for last autumn there are only six of these. Then, again, we find a very large number of Teas, and a considerable quantity of Hybrid Teas. Of the latter it is impossible to say until we have an opportunity of seeing them whether they are really Hybrid Teas, or are so like either the H.P.'s or Teas that they should be classed among them. Messrs. Paul & Son say very truly in their catalogue that in some of these the Hybrid Perpetual strain is so marked that they ought to be included in that class; while, again, there are others in which the Tea percentage is so strong, as in Kaiserin Augusta Victoria, that they might very well be included in the Tea class.

Another point is that so many of the British-raised Roses are now included in their catalogues. I notice one curious error in Guillot's new catalogue—viz., in ascribing Muriel Grahame to Dingie & Conard, the American raisers, thus depriving our old friend Mr. Brown of Reigate of the honour of obtaining it, and Messrs. Dickson & Sons of sending it out. The altered circumstances with regard to the French Roses have been accentuated by the considerable number that we now have of home-raised flowers. These are from time to time exhibited, and rosarians have the opportunity of seeing them at our exhibitions, and so being able to judge of their value, or otherwise, without trusting to the magniloquent descriptions which the foreign raisers attach to their novelties.

In looking through the list of novelties of the last few years, it is a very remarkable fact that not one Hybrid Perpetual of foreign origin has been of sufficient value to be placed in our catalogue; thus, in the supplement of the National Rose Society, published in 1896, there is not one H.P. of foreign origin. Comtesse de Ludre is indeed there, but then it was a Rose raised in 1880, and owes its introduction in the list to one very fine bloom shown at the Crystal Palace Exhibition; it is, however, I believe a very uncertain Rose, and I do not think it will be found in many stands. Duc d'Orleans, a Rose of 1889, also raised by Eugène Verdier, has found a place there, but it is not a very well-known Rose, though some growers speak highly of it. It is, in truth, amongst the Teas and Hybrid Teas that the French growers try to keep up their reputation. For instance, there is that grand Rose Mamah Cochet, sent out in 1893 by Cochet, which has established for itself a high position. It is of a deep flesh colour, with rose tints in the outer petals, and sometimes they are edged with bright rose, which make it very attractive. There is now announced a white Maman Cochet: should it be really white, and of the form and substance of the type, it will be grand acquisition to our white Teas.

Amongst our home-raised Teas Sylphe (W. Paul & Son), which was sent out in 1895, is unquestionably a fine flower. It is an ivory white tinted with peach colour, with a creamy pink centre; the petals are very deep and stiff; the habit is vigorous, and very free-flowering. Of Muriel Grahame it is hardly necessary to say anything. It is a distinct sport of Catherine Mermet, and resembles that flower in everything but colour. Doubts have been expressed in some quarters as to the vigour

of its growth. So many good growers have, however, expressed their high opinion of it in this respect that I think we may hope that it will prove as vigorous as the variety from which it sported. Mr. Piper of Uckfield seems to have found Catherine Mermet sporting in the same way in his nursery; and this has occurred with other Roses, notably with Souvenir de S. A. Prince. Corinna is another of Messrs. W. Paul and Son's acquisitions to which I think justice has hardly been done; but I do not fancy anyone will regret having it in his collection. The colour is flesh, shaded with a deeper pink, the shape being semi-globular with a pointed centre.—D., Deal.

(To be continued.)

NOTES ON ALPINE FLOWERS.

(Continued from page 328.)

PRIMULA SPECIES.

By this conventional name are designated various members of the genus *Primula*, which have not come under recognition as florists' flowers. Some are true species or their varieties; others are natural or garden hybrids. Nearly all are of much beauty, and have received not undeserved attention from many growers of alpine flowers. At this time it may be opportune to say a little about some of these flowers, with a view to bringing them under the notice of those interested in the plants which form the general subject of these notes.

PRIMULA DENTICULATA.

This is one of the best known of the *Primula* species, although less common in many gardens than its variety or sub-species *P. cashmeriana*. It is, perhaps, less variable in its colouring if raised from seed than the latter, but this is not to be regretted, as the Toothed Primrose has flowers of a more refined colouring than are those of the Cashmere variety. It was introduced from the Himalayas, and has been figured several times. It is difficult to render in words the soft yet bright colouring of *P. denticulata*. It is called "bright lilac," and as one cannot suggest a more exact description that must stand for the present. The flowers are about half an inch across, and are closely arranged in a round head or umbel. It grows from 6 to 12 inches high.

It is recommended that it should be grown in leaf mould, and in a moist position. The writer has been experimenting with this *Primula*, and finds that it produces finer flowers if grown in a well-drained soil, which is dry during the winter months, but is kept moist in spring and summer. *P. d. pulcherrima* has taller stems, larger heads, and brighter flowers. *P. d. cashmeriana* has the under surface of the leaves densely covered with a gold dust-like meal. There are also white varieties of both. *P. denticulata* and its varieties can be increased by division or seeds. It comes into bloom early in the year if the weather is mild.

PRIMULA PALINURI.

The Palinuri Primrose comes from Southern Italy, but is quite hardy on well drained rockwork. It is of very different habit and colour from the preceding species, having bright yellow flowers arranged in a drooping umbel. It comes into flower in April and May, and its pretty bright flowers, with a perfume like that of the Cowslip, and its bright, pale green, toothed leaves of large size, make it a very attractive plant. The flower scape is covered with white powder. It may be increased by division or seeds. A compost of sandy peat is suitable for this Primrose if in a half-shady situation, with a moderate supply of moisture in summer.

PRIMULA INVOLUCRATA.

This *Primula* from the North of India is a general favourite, although there are many more brilliant flowers in the genus. Its beauty consists more in the quiet, yet pleasing colour of its creamy-white flowers, with their yellow eye, than in the more gorgeous hues of some species which attract the attention at once. The leaves are a pretty green, and the whole plant only grows 6 or 8 inches high. It is with us a bog plant, or at least one which requires to be grown in sandy peat always kept moist. It is increased by seed or division, and, like many of the genus, requires occasional top-dressing when it raises itself above the soil. The roots are sometimes disturbed by frost, and it is well to look the plants over occasionally to see if they need top-dressing or pressing down.

PRIMULA MINIMA.

This miniature growing plant, known as the Fairy Primrose, is rather a difficult plant to grow. In this respect it compares unfavourably with some of the hybrids of which it is one of the parents. A good treatment is to plant in well-drained fissures in rockwork in rich loam and grit, and never to allow it to become dry in spring, summer, or autumn. It is, perhaps, the smallest of the species, but its flowers are very large in proportion, being sometimes an inch in diameter. They vary from pink to violet, and are sometimes almost white. The leaves, toothed at the top, are about half an inch across. The stock may be increased by careful division.

PRIMULA STEINI.

This is a bright and attractive *Primula*, which is very well worth growing, and gives a good effect to the portion of the rock garden in which it grows. It is said to be a hybrid of *P. minima* and *P. hirsuta*. It is not difficult to grow wedged between two stones on moist, half-shaded, and well-drained rockwork. The flowers are bright purple, and are produced on very short stalks. The leaves are what are known as

spathulate-obovate, and are toothed. This *Primula* is very pleasing in every way, and the habit is so dwarf and compact as to make it suitable for positions where larger plants would be out of place. It may be increased by division.—ALPINUS.

(To be continued.)

GOLDEN PRIMROSE JOHN WILKINSON.

I AM sending for your inspection and opinion a yellow Primrose. In the summer of 1896 a small plant of it was given to me by the raiser, the wife of a gardener in our neighbourhood. From that one plant I have now in front of my window nineteen plants in glorious bloom. From the plants sent you will be able to judge of the habit, colour, and form of the flowers. It is a very free and most profuse bloomer; during the whole of last winter it was never without flowers. For a yellow bed in spring I have not seen anything to equal it; not only is the deep yellow colour so telling, but the form of pip and truss gives it such a pleasing and charming appearance.—N. N.

[Two plants were received from our correspondent, and one of these we sent to Mr. S. Arnott, who thus writes:—"The plant sent for inspection is a fine yellow Polyanthus of bold and sturdy habit, and with large trusses of handsome deep yellow flowers. It should be very effective as a spring bedder or planted with other flowers. If, as you say, it is a good winter bloomer, its value is much increased, and the variety should be largely propagated. Deep yellow Polyanthus of similar shades are much appreciated, and yours is much darker and brighter than the majority. The flowers are well formed, but pin-eyed (which, however, is of no consequence for decorative purposes), and borne well above the foliage on remarkably sturdy stems. We have recently seen a strain of exceptional merit, which contains a few flowers of nearly equal merit. These were the result of many years' selection." We have also seen effective forms of yellow bedding Polyanthus, but did not observe at the recent show of the National Auricula and Primula Society one in all respects so good in its way as the golden yellow John Wilkinson.]

A FRENCH SEWAGE FARM.

A LARGE sewage farm has been laid out at Achères for purifying the Paris sewage before allowing it to pass into the river Seine. The inhabitants of Paris number upwards of 2,500,000, and the total flow of sewage is stated to average 17,660,000 cubic feet per diem. This is collected in great intercepting sewers, which convey it by gravitation down to Clichy, where it is raised 118 feet by powerful pumps, and distributed by gravitation through the farm. The pumping engines at present installed are capable of indicating 1200 horse power in the aggregate, but future additions will raise this to 6000. It is stated that experience shows that 1 acre of suitable soil can take 1580 cubic feet of sewage daily, so that an area of about 11,120 acres would be needed to deal with the whole of the discharge of the Paris sewers. A very high degree of purification is reached, the effluent proving to contain fewer bacteria per cubic centimetre than most uncontaminated streams. The land also has been greatly increased in value, being now worth five times as much as it was before being made the receptacle for the sewage. As a natural consequence, says a contemporary, neighbouring landowners, who originally had fiercely opposed the establishment of a sewage farm in their midst, are now claiming to have the sewage supplied to their own properties. The farm at Achères is 2471 acres in extent, and is under the control of M. Bona, a civil engineer, who in the main raises Beetroot, though this crop will admit of much less sewage being passed on to the land than certain others. The main conveying the sewage from the pumping station is 43.2 inches in diameter, whilst a secondary system of pipes, ranging from 31 inches to 16 inches in diameter, serve as feeders to the irrigation trenches, into which the sewage passes through 11½-inch valves. The ground is laid out, and the irrigation trenches are so arranged that the only service needed in regulating the flow is the opening or closing of the regulating valves just mentioned. The crop which can stand the most sewage is grass, a meadow being, it is stated, uninjured by a flow of 2,430,000 cubic feet per acre per year: Lucerne can take 1,790,000 cubic feet per annum; Artichokes, 593,000 cubic feet per annum; flowers, Parsley, and Sorrel, 536,000 cubic feet; Leeks, Cabbages, and Celery, 325,000 cubic feet per annum; whilst Beetroots, Carrots, and Beans will take only 197,000, and Potatoes, Asparagus, and Peas but 141,000 cubic feet per acre per year.

CINERARIAS.—In addition to growing one or two of the best of our English strains of Cinerarias, I have also taken care to include the red, white, and blue strains sent out by Vilmorin & Co., which are really admirable. Of late years much improvement has been manifested in the dwarf habit of the plants, and the freer blooming and finer form of flower, and their earliness in flowering. Purchased separately one never gets mixed, every plant coming true. The red is a fine bright shade, the white too is excellent, but in the blue every conceivable shade can be noted. The two former are large flowering, and the latter small, compact, and a gem for cutting, for supplying a colour for conservatory decoration that we too often lack. To those who cannot accommodate the three varieties, I would advise the latter as a thorough acquisition, certain of being admired.—R. P. R.

FERN NOTES.

AT all seasons of the year we admire the grace and elegance of our hardy and exotic Ferns. There are very few gardens in which they do not find a place, and where their culture is not attempted with more or less success. Year by year they are increasingly cultivated, and, as a consequence, continued efforts are made to obtain new species and new forms to supply the demand. Some exceedingly handsome species have been introduced within the last few years, and many elegant and handsome forms of the old species have been selected.

Perhaps the most graceful, or at least the most useful, of all Ferns is *Adiantum cuneatum*. It is very easily cultivated, the mature fronds keep well after they are cut, and there is none more useful for buttonhole flowers, bouquets, or to mix with cut flowers for any decorative purposes—indeed, seldom is any other species used for the best bouquets in Covent Garden; but the mature fronds ought only to be used, as young foliage very quickly shrivels. The true British Maidenhair is much like *A. cuneatum*, but it has larger pinnules, and does not grow so freely; it requires similar treatment to *A. cuneatum* when under cultivation, and is most at home in a cool stove. Several distinct forms of this have been raised. *A. capillus-Veneris* admirabile has fronds more wavy and graceful than the original. *A. capillus-Veneris* daphnites is a more dwarf form of the species, and the fronds have larger pinnules. *A. capillus-Veneris* magnificum and undulatum are also very desirable, and should be in all large collections.

Of exotic species of *Adiantum* some have the young fronds tinged of a deep red colour. A small-growing very neat species is *A. tinctum*, but it is not of free growth. *A. Veitchianum* has fronds of the deepest red, and is very free. *Adiantum asarifolium* is a very novel species with simple orbicular fronds, when full grown about 3 inches across. It should be grown for its distinct character. *A. concinnum latum* is a charming form of the species; the fronds are more erect in growth. *A. farleyense* is the most magnificent of all, but as it does not produce fertile fronds it can only be increased by division. It is not so easily grown as most of the other species, and requires rather different treatment. Most of the *Adiantums* thrive with a fair supply of air, and should get a little sunshine; while *A. farleyense* is much affected by draughts, and the fragile delicate pinnules are injured by sunshine.

The potting materials for *Adiantums* should be about equal parts of tough fibrous peat and turfy loam; a little silver sand and a few pieces of charcoal ought to be added to keep the whole porous. The repotting of Ferns should be done with care; if the ball has become matted with roots prick amongst them with a pointed stick until they are loosened out, but do not break the ball of earth. Some of the old spent mould may be removed from the surface. The pots to be used must be clean, and they should be one or two sizes larger, according to the vigour and species to be potted. One large potsherd should be placed at the bottom of the pot, and the smaller pieces, which should be quite free from dirt, placed over it in a careful manner. The compost should be packed round the ball rather firmly, but not quite so firmly as is done with hardwooded stove or greenhouse plants. Do not water the plants immediately after they are repotted. Experienced cultivators of pot plants do not require to be told about it; but I have seen expensive plants taken to the potting shed, shifted into another pot, and watered on the hand-barrow before being removed to the stove or greenhouse, which is barbarous treatment, and highly injurious to delicate plants. Frequently I do not water plants for a week or ten days after they are repotted (when the operation is performed early in the season), and by that time fresh rootlets are formed and ready to take up the water when it reaches them. The same treatment applies to all classes of pot plants.

The *Davallia* is a useful genus of Ferns, and nearly all of them are adapted for small houses. *D. Mooreana* is a noble and very handsome species. Its broad arching fronds are between 2 and 3 feet in length. It is a stove Fern, having been introduced to this country from Borneo. *D. parvula* is one of the smallest of the species; the fronds are only a few inches high, but are finely divided and very neat. *D. Tyermani* is very distinct, and similar in size to the last. It is well adapted for basket-work, and was introduced from the west coast of Africa.

The Gold and Silver *Gymnogrammas* should be grown in all plant stoves, but they ought to be placed in a part of the house where they are out of the reach of the syringe, as sprinkling sadly disfigures them. *G. Laucheana* makes a neat medium-sized specimen, and the gold powder underneath the fronds is of the deepest yellow. *G. chrysophylla* is also a very desirable species, slightly powdered on the upper surface and golden yellow underneath. Of the silvery species, *G. tartarea* and *G. argyrophylla peruviana* are good. A very elegant species named *G. decomposita*, the fronds of which are finely divided, has a very graceful appearance.

The *Lomarias* are an easily cultivated class, and some of the species are very pretty. *Lomaria gibba* is very easily produced from spores, and in a small state it is very pretty as a table plant. *L. gibba crispa* is a small-growing form, which is also very pretty in small plants, but it does not make a handsome specimen. *L. gibba Belli* is well deserving of notice, as it makes a handsome specimen, and very seldom produces fertile fronds. The fronds are similar to those of the species, except that the ends are singularly tasselled.

It would occupy too much space to describe half what ought to be grown in collections. A few more remarks on culture may be added. Except Maidenhairs, already mentioned, most stove Ferns thrive in turfy peat, with a very little loam added to it, and when the pots are well filled with roots a good supply of water is required. Too much water before the pots are tolerably well filled with roots, and overpotting, will cause

the soil in the pots to become sour, after which the plant will not thrive. During winter a high night temperature is not desirable, 55° will be quite sufficient; nor should they be syringed at this season, although the atmosphere must be pretty well charged with moisture derived from water scattered about the floors and stages. If the weather is fine the plants may be syringed during the spring and summer, except the *Gymnogrammas*, which are disfigured by the syringe being used upon them; and as young fronds will now freely be produced by increased warmth, the house will be required to be shaded during hot weather. Ventilation requires, perhaps, more attention during this than any other month of the year. Unless great care be taken vegetation suffers from the drying winds which we have, often accompanied by frost. Admit very little air at such a time, as it will be better to shade to keep down the temperature.

Ferns are subject to the attacks of various insect enemies. Where mealy bug is plentiful it gets upon the fronds of some of the species, and can seldom be dislodged without injury to the plant. Others are attacked by thrips, while green fly will also attack the young fronds of *Lomarias* and check their growth. These must be destroyed promptly.—GROWER.

BALDRY'S SCARLET DEFIANCE RHUBARB.

THE note of "N. N." on this Rhubarb (page 376), your editorial comment, with its complimentary finale, and the arrival here of a box of stalks from "N. N." have made it necessary that I should say a few words on the subject. First, however, let me thank you for putting "N. N." in communication with myself, and then thank him for his kindness in sending some of his Rhubarb to me for comparison, and still more for the very friendly letter which accompanied it. It was a true brother gardener's epistle, and it is needless to say, I hope, that I replied to it with becoming friendliness.

Now for a word on Baldry's Scarlet Defiance Rhubarb, and its comparative state of unknownness—if I may coin a word to express its small area of cultivation. My great experiments were made in the late seventies and early eighties, and I have to fall back on my memory, which, as we old people know, is not so alert or retentive as it was in the first four decades of life. This Rhubarb, Baldry's Scarlet Defiance, Salts' Crimson Perfection, Reading Ruby, and one or two others, were dropped out of the competition, I know, because they proved "too slow," or, in other words, they did not satisfy the requirements as to earliness, productiveness, colour, and flavour.

Those four points were the criteria of judgment, and, though each variety might have some one point or more excellent, as Baldry's for colour and flavour for instance, the other points were not fulfilled in some way or other. Time is the great factor in life generally, and time, or earliness, is an important desideratum in a small-growing Rhubarb in a private establishment, and small-growing Rhubarbs are of no use in market gardens, unless they are exceptionally early. Our friend "N. N." seems to have a very good healthy form of Baldry's Scarlet Defiance, and, another important matter, his soil and climate appear to suit it. The stalks sent, on being cooked, were in every way excellent—composition, colour, and flavour; colour and flavour being particularly good.

The reason why it is not catalogued by traders may be inferred from the reasons I have now given. As far as my memory serves me it was catalogued about the time I was in the thick of my experiments, but it has fallen out lately. By the kindness of "N. N.," who offers me roots, I hope to renew acquaintance with it, and, on trial, if all goes well with us, I may have something to say at a future day.

I have reduced my varieties to the following on the common sense principle that every gardener acts upon, to grow only the best of everything that fulfils the requirements of the establishment which he serves:—

1, Chiswick Early Red, which, after all is said, is the very earliest to come naturally in the open ground. It, however, is very closely run by (2) Hawkes' Champagne, which is my mainstay. Here, however, I may give a very curious instance of a sort of race between this and Chiswick Early Red. They grow almost side by side, and under the same conditions, or nearly so, and in some years they are so close together in coming in that I have pulled them on the same date, but as a rule Early Red has the first honours as to earliness. 3, Lister's Cherry Red, once sent out by Messrs. Fisher & Holmes of Sheffield as *Prima Donna*. This is a little later than Hawkes', but is as red, and has a more refined and more delicate flavour. When the cook wants anything special as to refinement in Rhubarb, then Lister's is pulled for the purpose. 4, Salts' Crimson Perfection.—This is grown only in small quantity, and that to satisfy a certain lady, who admires its colour; and then 5, and last, Victoria, grown almost on purpose for forcing in the Mushroom house and for the making of jam.

All of the Linnæus breed of Rhubarb I have let go, though I kept Johnstone's St. Martin for a long time. It was such a good summer sort, but its lack of colour was against it. The giant sorts, as Stott's Monarch, are of no use in a gentleman's garden; they are too large and coarse, and lack colour. When I was working my Rhubarbs, Messrs. Stuart & Mein of Kelso told me that they had a variety coming on which was a cross between Stott's Monarch and Victoria, with the size of the first variety and the colour of the latter, but I have not heard anything more about it; otherwise, with size and colour, it would do for market work, and perhaps to grow for forcing in private gardens.

I think I have indulged myself enough now, but have much enjoyed the reopening of what has been, and is, to me a very interesting subject, and my thanks are due all round, but especially to the Editor and to "N. N."—N. H. POWNALL, *Lenton Hall Gardens, Nottingham*.

FRITILLARIA TULIPIFOLIA.

AMONGST the many species and varieties of Fritillarias there are some flowers of the quaintest beauty, and many of the comparatively unknown species are worthy of more attention. A collection would lend interest to many gardens, and yet it is very seldom that one meets with them, except perhaps such as *F. meleagris* and *F. imperialis*. These ought of course to be grown, but others should be added. The culture and propagation are not difficult, and plants may be grown in borders or in cold frames if desired, but they do not, as a rule, thrive so well in pots as when planted out. *F. tulipifolia*, about which "F. L. O." asks, is a dwarf Caucasian species, remarkable chiefly for the peculiar glaucous blue colour of its flowers externally; internally they are brownish red. It is a variable species as regards size. This species was introduced into this country in 1872, and is portrayed in the woodcut, fig. 75.

THE NATIONAL AURICULA SOCIETY'S
SOUTHERN SHOW.

No grower of Auriculas could have anticipated a good exhibition this year; in fact, it has been one of the most extraordinary and disappointing seasons that has ever been experienced. One of our largest southern growers wrote in the somewhat following terms to me in February:—"What a pity it is that the R.H.S. has fixed so late a date as April 27th for the show. The southern growers will be quite out of the running, as all our flowers will be over; it will, however, give the northerners a chance." I met him, however, on April the 12th, when he said to me, "Although I have got nearly 800 flowering plants, I have not more than two dozen in flower," and those of course were mostly selfs, which are always earlier than the edged varieties, and this was universally the case, the north and south telling the same story; and though the flowers did push very vigorously earlier in the season, the cold and harsh easterly winds in March and the early part of April completely stopped their growth.

This state of things had not only the effect of preventing the plants from being in flower in good time, but also of hindering the character of the bloom, for I think most florists must have noticed that when a flower is long on the way it is never of good quality. One was therefore not surprised to find large empty spaces on the tables, and that the quality of the flowers was very much below the average; and so far was it from being a time for the northerners, they were conspicuous by their absence, and an Auricula show without the Rev. F. D. Horner was like the play of Hamlet with Hamlet left out. Nor was good old Ben Simonite able to put in an appearance. A message came from Mr. Horner that he had nothing in flower, and hence one item which always gives an interest to these exhibitions was absent—viz., the bringing forward of seedlings which mostly come to us from the north. Another matter which bears out my view of the exhibition was the paucity of some of our best flowers; thus I did not see a single specimen of Prince of Greens, and George Lightbody, which so often has taken nearly all the prizes in the single grey edged flowers, was very sparingly represented, and this year it was not exhibited in this class. It is, generally speaking, a late flower, which would in some measure account for it. Many of the flowers exhibited also evidenced that they had been subjected to severe pressure, and the Auricula ever resents the idea of heat, as a very eminent grower expressed to me. If you force the same plant two years successively you must injure it, even if you do not kill it; nor do I think the flowers are nearly so refined when they are subjected to it.

Of seedlings there were comparatively few, and no edged variety seems to have claimed any distinction. A fine self exhibited by Mr. Phillips, named Mrs. Dranfield, received the first prize. It was a rich deep, purplish blue with a good paste and stout stem, and is likely to prove a valuable show variety.

It must not be supposed, however, that there were not many good flowers to be seen. Mr. Douglas's stand of twelve was unquestionably the best in the show. Especially fine was Olympus; while his George Lightbody, though perhaps not equal to blooms which he has before exhibited, well maintained the character of that grand flower. Mrs. Henwood certainly now stands at the head of the green-edged varieties. Mr. Douglas's truss of it was very fine, and so also was Mr. C. Phillip's, shown in the class for six; it is, I believe, a northern flower, and seems to be of a good constitution. Abbé Liszt, raised by Mr. Douglas, is another flower which has made a great advance in the same class of green edges, and it obtained the honour of the premier Auricula in the exhibition. Amongst other noticeable flowers there were good blooms of that fine white-edged variety John Simonite, which is well known as a very difficult one to manage, but it is certainly one of the purest white edges that we have. It was also noticeable how again the late Mr. Woodhead's seedling Auriculas were at the front: thus in the four prizes obtained for the best grey-edged variety three of them were secured by George Rudd and Rachel, two of his seedlings, and the same flowers appeared in several of the winning stands, as also did the two others, Mrs. Dodwell and Black Bess, and when we remember that only these four were ever sent out by him, it is surely a great distinction to have been the raiser of such flowers. As I have never been a grower of Alpines or Fancy varieties I do not feel that I have any right to say anything about them, though I believe the Alpines were especially fine, and although

there were only two exhibits of Fancy Auriculas they were very much admired.

It is very pleasing to notice new exhibitors coming forward, for we have to remember the Auricula is never likely to be a very popular flower. One very able horticulturist, who has made his mark in other flowers, said to me on Tuesday, speaking of the exhibition at the Drill Hall, "It would be a very nice one if it were not for the Auriculas," and when I remonstrated with him, and asked why he uttered such a heresy, he replied, "Oh, they are so stiff and formal, and the colours are so decided, and don't blend into one another;" and I am afraid this is a very general opinion concerning them, and yet there is no flower which so retains the affection of those who have cultivated them for any lengthened period; and when I remember how low the culture of them had fallen in the neighbourhood of the Metropolis, I see how very much has been done during the past

FIG. 75.—FRITILLARIA TULIPIFOLIA.

few years. The present position of the Society is largely due to the zeal, intelligence, and tact of its excellent Secretary, Mr. Henwood, and much sympathy was expressed for him, in that when he had reached a very topmost place amongst exhibitors in the South, he was obliged to abandon the culture of his favourites owing to ill-health.

Of course my opinions about the show may be challenged, and others may form a different estimate of it, but it must be remembered that I am a florist of the old school, brought up in the strictest sect of Auricula growers, to whom coarseness was ever an abomination, and who holds to the rules laid down both as to flowers and plants maintained by that school of Lancashire florists who made the Auricula what it is; and I hope that this idea of its true character may be upheld by those who have now entered the ranks of Auricula growers—D., Deal.

GARDEN TEACHING IN STAFFORDSHIRE.

IN connection with the important question of keeping the rural population on the land, providing them with remunerative employment, and enabling them to make the most of a limited income, the Staffordshire County Council some three years ago started ten experimental schools, following much the same lines as had been adopted in Surrey, but providing a more complete equipment. At each centre twelve plots are provided, which are of equal size, and each plot is worked by one pupil. The County Council provides the seeds and manure, and lends at each centre a toolhouse, a wheelbarrow, and the necessary tools for twelve pupils. The pupils pay a small fee, which is usually about a shilling, for the session: this fee is intended to cover the rent of the plots, and usually, as a reasonable rent is charged by the local landowner, this amount is sufficient to cover the expense. The produce of each plot belongs to the pupil, and in several cases last year, in addition to what the pupil used off his plot, money was realised from the sale of the produce of one plot which would have been sufficient to defray the rent of the whole of the plots at the centre.

During the present summer there will be twenty-five centres, and instruction will be provided for 300 pupils. The teachers are not unfrequently the rural schoolmasters, who are selected partly from the fact that they have shown their practical skill by the way in which their own gardens have been cultivated, and partly from their possession of the certificate of the Royal Horticultural Society, the double qualification being insisted upon. In other cases the head gardeners of noblemen or gentlemen in the localities have been allowed to act as teachers, Lord Harrowby's gardener being in charge of the school at Sandon, and Lord Hatherton's gardener of that at Penkridge.

For the coming session it has been decided to provide an additional plot at each centre for the cultivation of small fruit. This plot will be under the direct management and control of the teacher, and contain six Gooseberry bushes, six Currant bushes (including Black, Red, and White), a row of Raspberry canes, and two rows of Strawberries, while space will be left for propagation. The plants have been selected by Mr. Cock, the County Instructor in Horticulture, and supplied by Messrs. Dicksons of Chester. It will not be possible to do very much until the plants have made some growth, but in future regular instruction will be given on the cultivating, pruning, and propagating of small fruit bushes, and it is hoped that the result will be not only to encourage the growth of small fruit throughout the county, but to introduce to the notice of cottagers a number of improved varieties of Gooseberry and Currant trees, and also of the best kinds of Raspberries and Strawberries, as the pupils will be able to propagate these for themselves, and thus to introduce them into their own gardens.

Village Gardening Schools and Their Cost.—Schools are intended specially for the young labourer or under gardener. Exceptionally a pupil will develop marked skill or aptitude such as would mark him out for the position of head gardener or for the business of a market gardener. In such cases a thorough course of instruction, extending over at least two years, is desirable. This higher form of teaching is provided at colleges. In Staffordshire a scholarship of £50 per annum is offered each year to enable promising pupils to proceed to a horticultural college, and to remain there for two or three years. In various other counties similar horticultural scholarships are also awarded. The labourer's son in even a remote village is thus able to start with instruction provided at his own door, and to pass on to the best gardening colleges in the country.

In Staffordshire the payments to the teachers and the equipment of the schools is conducted on a liberal scale, and everything supplied is of the best quality. The Committee insists upon at least forty school lessons being given, each of at least two hours' duration, and the teacher's remuneration is calculated on the basis of 2s. 6d. per hour. The initial cost at a new centre for the provision of toolhouse, tools, wheelbarrow, and for the preliminary rough digging and manuring, varies from £12 to £15, while the subsequent cost averages about £12 per centre, or £1 per pupil per annum. This cost, however, does not include the proportion of time devoted by the county horticultural lecturer, or to organisation and visits of inspection.

It is thought that by training the young man to intelligently understand the reason for the operations he performs, to cause him to read and to think, and thus to enable him ultimately to make two blades of grass grow where one grew before, our rural population can be maintained, and the migration of all that is best from the country to the large centres of population prevented.

THE YOUNG GARDENERS' DOMAIN.

A PILL FOR A GRUMBLER.

MANY probationers who take interest in the "Domain" must have had a grin over the remarks of "Grumbler" on page 356. He writes with all the confidence of a sage, and if he had not stated that he was a foreman one might have pictured him as a self-satisfied old fogie, and a famous hand with the spade. There are two sides to every question. I write as a foreman who has had experience with young gardeners, some who paid premiums and some who did not; and though here and there one meets with a black sheep, as in all other capacities, our young men as a body are, in my opinion, as able, energetic, industrious, and intelligent as the probationers in any other occupation. Since the "Domain" has been opened I have noticed the improvements made by some of those who take advantage of it, and would remind "Grumbler" that nothing succeeds like success. We never know what we can do till we try, and

it is an easy thing for one to resign himself to the happy fate that he has not the necessary ability before he makes an effort. Many of the best writers of the day remember a time when as beginners they tried over and over again before success crowned their efforts.—ANOTHER FOREMAN.

[Very true; and this particular foreman has had, and now enjoys, a better reward for his perseverance than he at one time anticipated.]

TYING VINE SHOOTS.

THE excellent advice by "Vitis" on this subject (page 348) is worthy of attention from all cultivators of the Vine. The perusal of the notes reminded me of an instance which fully corroborate the remarks there made.

A few years ago, when occupying a general foreman's place in the Midlands, we had a midseason vinery containing several varieties generally known as possessing greater "snapping" proclivities than others. The Vines in question manifested signs of an exceedingly promising nature. I was instructed to tie down the young growths, but foreseeing the inevitable disastrous results, I suggested it would be better to bring them down gradually. Anxious to meet the wishes of my chief, and at the same time to see creditable and satisfactory results, I pursued the latter course, merely keeping the ends from the glass.

But the gardener declared his intention of tying them down himself. The result was not noticeable till the following morning, when a sad spectacle was witnessed. Fully a score of the best shoots had snapped at the heel. After continued experiments and observation I find the most liable to snap are Black Alicante, Muscat of Alexandria, and Gros Colman. I must differ slightly from "Vitis," for in my opinion Black Hamburgh is one of the best for tying. In fact, I have repeatedly tied whole houses of them without a failure.

Great care should be taken not to place the tie too high, or the shoots will snap beyond the bunch. Bring the matting in a slanting direction, and if the wires run horizontally slip the tie along the wire until able to give the final one. Attend to this every alternate morning, and patience and perseverance will yield satisfactory results.—VINIFERA.

WINTER FLOWERING ROSES—FORTUNE'S YELLOW.

THE delicate Rose bud is always appreciated, but never so much as in the winter and early spring months, and those anxious to obtain them from December onwards may achieve wonderful results if a start is made at once. It is necessary at the outset to consider which are the most suitable varieties, and how to grow them in quantity. Failure in growing a bountiful supply often results from no other cause than growing a large number of varieties, the majority of which prove next to useless for the purpose. It is much better to abandon the idea of having a large number for the mere sake of having them.

There are many beautiful Roses recommended for winter flowering, but I think there is none that can surpass the old variety, Fortune's Yellow. Though despised by many who are only acquainted with it grown outside, with proper treatment under glass it produces an endless number of delicate orange coloured blooms, which are a source of delight to all beholders.

If anyone has a suitable span-roofed house in which to grow Tea Roses (planted out), this old variety cannot be too highly recommended, and no grower should be without it. Many others bloom abundantly as the season advances, but Fortune's Yellow flowers as freely in January as in April. It is also a remarkably good Rose for cutting, as the buds, if cut before they are fully expanded, open freely in water, which is not the case with many other sorts during the winter months. It has been grown in these gardens for several years with remarkable success. After being planted in a good stiff compost it is trained over the roof of the house; when it has ceased flowering it is rested for a short time, and then pruned back to about a couple of eyes, from which it grows most vigorously.

The only pest that ever attacks it is green fly, which is hardly allowed to show itself before it is eradicated by fumigation. Climbing Devonensis, Maréchal Niel, Gloire de Dijon, and Reine Marie Henriette are also excellently grown, but none can be compared to Fortune's Yellow, as its splendid foliage adds greatly to its beauty.—S. S., Lockinge.

PERSIAN CYCLAMENS.

THIS is one of our best greenhouse flowering plants, and as such is worthy of careful attention, and it is hoped these few notes may be of service to young gardeners and readers of the "Domain." Early in August clean, shallow pans should be prepared, first, by being well drained and then filled with a compost comprised of fine loam, leaf mould, and sand. The seeds should be sown thinly, merely covering them being all that is required in this respect. Place the pans in a shallow frame, having an equable temperature of 60°. A pane of glass should be put over each pan, covering this with a sheet of paper, as the seeds germinate more readily in darkness. Keep the soil moist, but on no account get it soddened, or disaster will result.

In about six weeks the seeds will have germinated, on the appearance of which the glass and paper must be removed and the seed pans placed as near the roof glass as possible. When germination has well taken place the pans should be removed to a house having a temperature of about 65°, again being placed near the glass. Keep the young plants moist, frequently spraying with the syringe. After being in this temperature for a month or so they may be taken to a house having a temperature of 55° to 60°, standing the pans on damp cocoa-nut fibre refuse, which will cause sufficient moisture around them at this season of the year. When the young plants are considered large enough they may be placed in 3-inch pots, retaining them in the same temperature, and standing them on damp fibre. A compost as advised before will be suitable for this potting.

Endeavour should be made to keep the seedlings growing steadily, being careful not to overwater, or they will damp off. As soon as these pots are well filled with roots the young plants may be transferred to 4 and 5-inch pots, according to the strength of the seedlings. The compost should consist of good fibrous loam, leaf mould, sand, with a little manure added. Pot firmly, raising the corm above the soil, as if sunk too deeply it is apt to decay. Keep the plants shaded from the sun both at this stage and in the earlier ones. A low heated house is best to place these plants in, where a temperature of 55° to 60° could be kept up should the weather prove cold. Use the syringe freely, both in the morning and afternoon, to induce growth and to keep the plants free from insect pests. As the pots become filled with roots gradually admit more air until the plants are sufficiently hard to be taken to a cold frame.

About the middle of September cease syringing and shading to induce the plants to have a hard sturdy growth. An occasional watering with weak liquid manure, or an application of some well proved fertiliser is very beneficial to them. Early in October house the plants where they are to bloom, previously cleaning the pots so that all may have a neat appearance. The temperature ought now to range about 55°. Should green fly make its appearance an application of "XL-All" will successfully eradicate it. When flowering commences it is surprising what a wealth of bloom, and how long these Cyclamen will continue to produce it.—SEMPER.

HARDY FRUIT GARDEN.

Outdoor Vines.—When the buds have pushed far enough to show the bunches the process of disbudding may be commenced. The growths nearest to the main branch ought to be retained if fruitful. One shoot bearing one bunch of fruit is sufficient for each spur. The removal or reduction of other shoots which are superfluous or ill-placed should also be carried out, the ultimate object being to retain only growths for which there is room for ample leaf development.

The spur growths require stopping one or two leaves beyond the bunch, when the shoots have advanced as far. If no bunch is present, and the shoot is retained, allow about seven leaves to form, stopping at that point and at every subsequent leaf afterwards. Lateral growths developing below the bunch rub out entirely; also train-in any strong shoots for filling vacancies, not stopping them before they have made growth 4 feet in length. Tying-down must be done gradually. It is best, unless crowded, to allow them to advance well before tying finally.

Strawberries.—*Mulching.*—The application of a layer of manure with a view to affording nourishment for the roots, conserving moisture, and forming a clean bed for the fruit when ripe, ought now to be carried out. Partly fresh farmyard manure is the best material. Should there not be a good proportion of litter among it, a layer of clean dry straw may be used later for the fruit to rest upon.

Feeding.—A dressing of nitrate of soda (1 oz. to the square yard) is a good stimulant for Strawberries given when the flower trusses show or just as the fruit sets. Water, liquid manure, or house sewage will also prove valuable aids in assisting the swelling of good crops of fruit and strengthening the growth, whereby bold buds will be built up for the succeeding year.

Young Plants.—Recently planted Strawberries or small plants placed out late in autumn ought not to be allowed to fruit this season. All should, however, throw up flower trusses; but when it is seen that they have done this pinch them off, thus encouraging the plants to make vigorous growth, and bold crowns produced. If planted in good soil on firm ground, hoed frequently, the runners kept closely cut off, and the soil lightly mulched in hot weather, there will be little difficulty in producing good plants.

Gooseberries.—Bushes showing any indications of being attacked with the larvæ of the Gooseberry moth should have the foliage dusted with soot and lime. Hellebore powder dredged over the bushes will kill all the caterpillars it touches, but as it is of a poisonous nature the green fruit when gathered ought to be well washed if this remedy is employed. The larvæ are very destructive to the leaves, completely eating up the green tissue. Soot is not only a good insecticide, but acts well as a manure, making the soil quite black with it. When bushes have set a good crop of fruit, and are free from caterpillars, a manurial mulch may be spread over the roots, which will largely assist the development of the crop by conserving the moisture in the soil. Cordon trees growing at the foot of walls will be especially benefited by a liberal mulch over the roots, further assisting them if the soil is dry by copious applications of water and liquid manure.

Red and White Currants.—Whether growing as cordons against walls or bushes in the open, a mulching of decomposed manure will be serviceable applied when the fruit is set.

Peaches and Cherries.—These trees are subject to early attacks from aphides, which infest the points of young shoots. Trees which may be growing in exhausted soil, or suffering from dryness at the roots, are almost certain to be attacked. In addition to well syringing the trees, and destroying the insects with some effective insecticide, the border must be thoroughly moistened to the full depth of the roots. Quassia

chip solution, softsoap mixture, soluble petroleum, Gishurst compound are all inimical to insect life, but every cultivator has his favourite remedies. Promptness in applying them when the insects are first seen is of great importance, and will prevent much labour in destroying them later on. If allowed to increase on the young shoots of Cherry trees to the extent they sometimes do, nothing short of dipping each individual shoot in a fairly strong solution, gently rubbing to displace the insects, will have much effect. For this purpose tobacco juice and softsoap is a safe remedy. Dissolve 2 ozs. of softsoap in a gallon of hot water, mixing in a pint of tobacco juice. Use when sufficiently cool. Give a thorough general syringing to the trees the following day, and frequently in warm weather.

FRUIT FORCING.

Cherry House.—With the fruit ripening syringing must cease, the Cherries being kept dry, but atmospheric moisture should be furnished by keeping the surface of the borders moist. Admit air constantly, as if condensation take place the fruit is seriously affected, cracking, and becoming impaired in quality. If necessary a thorough supply of water should be given to the border. Tie in the shoots as they advance, and stop those not required for training at about the fifth leaf. If black aphides are troublesome, dip the infested shoots or leaves in tobacco water or some approved insecticide, rubbing them gently with the fingers whilst wet. Ventilate freely on all favourable occasions, having recourse to the heating apparatus when the external conditions are unfavourable to insure a circulation of warm rather dry air. Trees in pots require abundant supplies of water and nourishment. Place some netting over the ventilators to prevent birds attacking the Cherries.

Vines.—*Early Houses.*—Where the Vines are infested with red spider or thrips let immediate remedial measures be taken, or not only will this year's crop be damaged, but next year's will be prejudiced. The judicious use of nicotine fumes or vapour is the best remedy for thrips, and to some extent for red spider, application being made on two or three consecutive evenings, repeating at intervals of a few days so as to destroy those escaping the first fumigation through being in the egg state. To annihilate red spider the use of sulphur on the hot water pipes has good results, they being heated to over 170°, and between that and boiling point, then damping the surface with a wet cloth, and at once sprinkling on the sulphur very lightly. The pipes should be kept hot for about an hour, the ventilators closed, and care taken not to give an overdose, and then the heat may be allowed to fall to the ordinary degree. Early Grapes that are ripe will only require enough fire heat to maintain a circulation of air, allowing the temperature to fall to 60° at night.

Second Early Houses.—The fruit of Vines started at the new year is commencing to colour. No great pains should as yet be taken to produce a dry condition of the atmosphere, as the Grapes swell considerably in ripening. Maintain a moist atmosphere in the early stages, sprinkling the house in the early part of the day and at closing time. Provide a little ventilation constantly, to induce a change of air and prevent the deposition of moisture on the berries. Maintain the temperature at 70° to 75° by day from artificial means, and 80° to 85° through the day from sun heat, falling to a night temperature of 60° to 65°, but 65° to 70° is necessary for Muscats. As the fruit advances in colouring the moisture should be reduced gradually, and the ventilation increased, but there must not be any diminution of the temperature until the Grapes are thoroughly ripe. The inside border must have due supplies of water or liquid manure, and a mulching of short material.

Succession Houses.—The remarks as to thinning, disbudding, stopping, and tying given in former calendars still apply—especially let all superfluous bunches be removed as soon as the number to be left on a Vine is decided. Examine the borders of all succession houses at least once a week, and when dry supply water freely. Inside borders will take almost any quantity of water after the Vines are in full foliage, and with a heavy crop of Grapes supply liquid manure at every alternate watering. Outside borders, except in special cases, will not as yet require water.

Late Houses.—The Vines making rapid progress must be tied, and stopped as soon as they have made sufficient growth to cover the trellis with foliage. Every care should be taken to secure good colour and firm texture in the leaves by free yet judicious ventilation. Take advantage of sun heat to increase the ventilation early in the day, but close early, excessive fire heat being injurious and costly.

Unheated Houses.—The Vines are making rapid progress, and in many instances the growths will require disbudding, stopping, tying, and otherwise regulating. One shoot is sufficient to each spur, unless they are wide apart, when two may be left. Reserve those that show the best bunches, rubbing the others off. Stop two joints beyond the bunches, but rather than crowd the foliage stop to one joint. Tie down the shoots carefully and gradually. Old Vines sometimes do not bear freely on spurs, being weak. It is best to lay in shoots from the base and along the rods at intervals of 2 or 3 feet in such cases to increase the root action. Apply a light dressing of artificial manure to the border, and point it lightly in. Inside borders may be given tepid water or liquid manure, when dry a thorough soaking, and a mulching of short rather fresh stable manure will, by keeping the surface moist, encourage active roots.

Newly Planted Vines.—With advancing growth—an evidence that the roots are active—close attention will need to be given to the roots to see that they do not suffer from over-dryness. Allow all the wood to remain that can be exposed to light, but supernumeraries intended for fruiting next year should be confined to one rod or cane, and the laterals pinched at the first joint, and to that of subsequent growths, stopping the canes at 6 to 8 feet.

THE BEE-KEEPER.

STARTING BEE-KEEPING.

WHEN is the best time to start bee-keeping? is a question we are often asked; and as we recommend spring in preference to autumn for beginners to make a commencement, a few notes on this subject may now be of interest. There is great advantage in making an immediate start, as a healthy stock or swarm early in the season, if carefully managed, should more than pay for itself the first year. But which is preferable? someone may ask. We prefer a stock headed by a queen reared last summer, and as there are numerous stocks of bees still kept in straw skeps in various parts of the country, these may usually be obtained at a reasonable rate.

For preference select a cast, or an old stock that swarmed last year; the former will have combs of a better colour than the latter, but this is of small consequence, as they will be melted down at the end of the season.

But what is of more interest to the bee-keeper, each colony will be headed by a young fertile queen. Before selecting a stock, observe the bees at work during the middle of a fine day. If they are passing into their hive at a rapid rate, each bee being laden with pollen, it will be pretty safe to assume they are in good condition. It is, however, advisable to examine the combs, to see if there is any trace of disease. Lift the hive quietly off its stand; if the bees are likely to be troublesome, a puff or two of smoke will drive them up between their combs. The latter should be straight, so that it is possible to see the amount of brood in each. At this date all the combs, with the exception of those on the outside, will be filled with brood in various stages of development. The hive, too, should be crowded with bees, and when found in this condition may be purchased, with every prospect of the bees doing well.

If a swarm is preferred, obtain it as early in May as possible; and should the weather be at all unfavourable after being hived, feed with warm syrup each evening for a week, or as long as the bees may require it. They will then take advantage of the first spell of fine weather, and store a surplus; whereas if left to take their chance, but little headway would have been made.

TREATMENT OF BEES IN SKEPS.

If the bees obtained are in straw skeps as above, it will be an advantage to obtain a swarm from them as early as possible, and it is better for the beginner to allow them to swarm naturally than to attempt to take an artificial swarm, although the latter operation is very simple when the operator has had a little practice. It is safe to allow the bees to settle the swarming business themselves until experience is gained.

Bee-keepers should remember that it is only during hot or bright days that bees will swarm naturally, and if the weather is dull and cold for several days in succession, it is no uncommon occurrence during unfavourable seasons for two or three weeks to elapse in May and June when the bees have not obtained sufficient outdoor supplies for their daily requirements. When this takes place, although the bees may be on the point of swarming, the young queens being well advanced in their cells, the workers will tear down the cells and cast the grubs out of the hive. If stores are at all short in the hive they will also cast out the grubs from the drone cells, and last of all from the worker cells. This shows the necessity of giving them timely attention.

Instead of leaving stocks to chance at this critical period they are provided with thin syrup daily until a change in the weather takes place, all will go on well. The bees will increase at a rapid rate, and although the young queens may be destroyed, others will be raised, and the first fine day that comes there will probably issue a strong swarm from this colony, followed by a cast a few days later. This will be in marked contrast to those that are left to take their chance when the weather is unfavourable. If treated as advised above success instead of failure will be chronicled.—AN ENGLISH BEE-KEEPER.

AN IMPROVED GARDEN HOSE.—The trouble experienced by many persons with garden hose bursting, kinking, or rotting is met by another important improvement in this article by Messrs. Merryweather. This firm has been successful for many years in manufacturing durable garden hose. The latest method of securing durability for the hose consists of an external coating of fine quality rubber of substantial thickness, which effectually prevents the canvas plies being soaked with water, as in ordinary hoses, and prevents rotting, which soon means the destruction of the hose. The ends of each length are also hermetically sealed with rubber to protect the canvas from water. To give flexibility, this has an internal coating of the best and most pliable rubber, and thus kinking and consequent stoppage of the flow of water, causing bursts in the hose, is prevented.

TO CORRESPONDENTS

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," **8. Rose Hill Road, Wandsworth, S.W.**, and **NOT** to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Cinerarias (E. A.).—The flowers sent are admirable for decorative purposes, and are probably from some good continental strain. These have not the perfect shape of the best English selections, but are by no means to be despised. Several of the specimens were between 3 and 4 inches in diameter. The flowers were of good substance and the colours splendidly diversified, while we observed on them some excellent specimens of the green fly, which is such a close ally to Cinerarias.

Daisies on a Lawn (C. F. M.).—The presence of Daisies in lawns is nearly always indicative of poverty of soil. An excellent dressing is a mixture of superphosphate of lime and nitrate of soda, two-thirds of the former and one-third of the latter applied during showery weather at the rate of 2 ozs. per square yard at intervals of a fortnight. If dry weather prevail it is a good plan to well water the lawn before applying the fertilisers, and then again afterwards to convey their virtues to the roots of the grass. Mixtures of guano and salt and soot and salt also act beneficially, so also do bonemeal and wood ashes. We mention these different ingredients in order that you may use what is the most convenient or readily obtainable. The most effectual mode of destroying Dandelions and Plantains is to drop a little sulphuric acid into the heart of each plant. Many persons have found lawn sand effectual in destroying Daisies.

Lophospermum scandens Diseased at the Collar (R. G.).—No doubt the soil has helped to produce the decay at the collar, as from the strong moisture-holding nature it would favour decay. We found, however, some root-stem eelworm (*Tylenchus obtusus*), and these, we consider, caused the decay of the root stem, the pest restricting its attacks to those parts of the plants, whether Cucumbers, Gardenias, Ixoras, Bouvardias, Carnations, Vines, or Tomatoes. The best remedy is an application of two parts air-slaked chalk lime and one part kainit, using 6 ozs. per square yard. Of course, the application will not restore plants to health that have their tissues destroyed, but it will prevent and check the spread of the evil. In cases of attack we have found Little's soluble phenyle effective, using at a strength of a wineglassful (two fluid ounces) to 3 gallons of water, or one part in 480 parts by measure, repeating occasionally.

Tomato Plants Diseased (J. B.).—The plants, of which you submit specimens, are infested by the Tomato "curl," "sleepy disease," or "sudden collapse" fungus (*Fusarium Solani*, syn. *F. lycopersici*) in a remarkable manner, the attack being confined to one side of the stem, and traceable in it to the base of the first flower truss. This the mycelium of the parasite has not entered, but was making its way there as fast as it could grow. The disease has evidently proceeded from the root, though you have not sent that portion, but only the side with roots attached. Immediately above these roots the bark has separated from the underlying woody layers, these being destroyed, but the bark quite sound, yet the said roots emanate from the diseased tissue, and inside the bark woody layers are formed. The phenomenon, therefore, somewhat resembles that of a hollow tree whose "heart" has been eaten out by one or other of the wood fungi, and explains the reason why earthing up Tomatoes affected by this disease may, by encouraging roots from the collar, prolong the life of the plants and insure fair crops of fruit. This, however, can only occur in certain cases, and in yours the fungus has got high up in the plant. However, you can try the placing of some fresh soil about the stems after first dressing the plants with air-slaked chalk lime.

Dusty Miller (*J. J.*).—We do not know whether the small flower you send is the veritable "Dusty Miller" or not, but we know that it very closely resembles *Primula Auricula*, and also know that the yellow form accompanying it is of thrice the size, and of infinitely greater decorative value. We will see if a comparison can be made with varieties of a similar character.

The Golden Club (*Improver*).—The botanical name of this plant, which is a handsome though scarce aquatic, is *Orontium aquaticum*. It is well suited for shallow water, but may be fully immersed when severe frost is expected. The fact of the plant being so rarely met with may be accounted for in a measure by its somewhat slow growth, and it is by no means one of the easiest to increase by division; at least, such is our experience of it. It was introduced into this country a century ago from North America, and as it is still only occasionally seen it is quite possible that it has never reached our shores in quantity, or that the majority of the earlier importations were lost. It does not produce seeds nearly so freely as many other members of *Aroideæ*, to which it belongs, and this also may contribute to its scarceness.

Smilax (*Myrsiphyllum asparagoides*) (*Amateur*).—Perhaps the freest growing and best plants are those raised from seed, which should be sown as soon as ripe. It is also increased from cuttings of the young side shoots with a heel or young shoots when about half ripe, or getting rather firm at the base. Insert in sandy soil surfaced with sand, and place in gentle heat, covering with a bell-glass, and keeping rather close and moist until rooted, then harden and place in pots. When the plants are large the roots or crowns may be divided into as many parts or growths as can be detached with a portion of root to each, operating early in the spring. A compost of good loam two parts and one part leaf, with half a part of sand, suits it. It succeeds admirably in a warm conservatory, and planted out where the growths can be trained up a pillar or rafter.

Chrysanthemum Leaves Diseased (*W. T.*).—The leaves, so far as we can discover, are not infested by rust fungus (*Uredo chrysanthemi*), but by the yellow leaf-spot fungus (*Ovularia chrysanthemi*), an undescribed species nearly related to *O. epilobi*, which causes the leaves to become yellow-spotted, afterwards brown and dead. It may be arrested by spraying with potassium sulphide, $\frac{1}{2}$ oz. to a gallon of water, or even with sulphuret of lime, but this article varies so much as to be less reliable than the liver of sulphur. The fungus is the chief cause of the leaves dying from below upwards as produced on the stem, and is wholly endophytic in mode of life, but produces the "fruits" or conidia externally, and by these the parasite spreads from leaf to leaf, not internally by mycelia in the plant. Give the plants more air and less stimulating food, using phosphates in preference to nitrogenous substances.

Gymnogramma chrysophylla (*Fern Lover*).—This charming and deservedly popular Fern requires a night temperature of not less than 55° in the winter and a moist atmosphere without the foliage being wetted. If your plant requires repotting use a compost of sweet leaf mould one-half, turfy yellow loam one-half, and fibrous brown peat one-fourth, adding one-sixth of silver sand, the whole well mixed and broken with a spade, but not sifted. Pot rather deeply, but not so much as to cover the crown. The plant should be set in the lightest part of the house, have room on all sides, and be not more than 18 inches from the glass. The soil should be kept moist, but not wet, until the roots are working freely, and the temperature may range from 60° to 65° by night. By day it may be 70° without sun, and from 80° to 85° with it, shade being afforded from 9 A.M. to 4 P.M., when the sky is clear, but when cloudy do not shade at all. No shade will be needed from September to April. The plant must always have the soil moist, but no water should be given until it is really needed, then afford a supply sufficient to show itself through the bottom of the pot. If your plant grow as well as we expect, it will need a shift by the end of July, or at latest by the third week in August, so that the pot may be filled with roots before winter, as it will be in six weeks after potting if a 10-inch pot be given. From that time no more water should be given than is sufficient to prevent the soil becoming dry, and if a sufficiently moist atmosphere be maintained it will winter safely in a temperature of 60° at night, and occasionally as low as 55° or even 50°, but this degree must be seldom reached.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*V. A.*)—1, *Saxifraga pectinata*; 2, *Tiarella cordifolia*; 3, *Ledum latifolium*; 4, *Kerria japonica flore-pleno*; 5, *Galeopsis dubia*. (*P. B.*)—1, *Doronicum excelsum*; 2, *Pyrus malus floribundus*; 3, *Spiraea prunifolia*; 4, *Trillium grandiflorum*; 5, *Spiraea bullata*; 6, *Aubrietia deltoidea*. (*W. W. J.*)—1, *Lonicera tatarica*; 2, *Doronicum caucasicum*. (*O. R.*)—1, *Primula verticillata*; 2, *Sanguinaria canadensis*; 3, *Scilla nutans*; 4, *Omphalodes verna*. (*Y. P.*)—1, *Oncidium Marshallianum*; 2, *Lælia purpurata*; 3, *Cymbidium Parishii*. (*Somerset*.)—*Sedum Rhodiola*.

OUR WONDERFUL WINTER.

It is a very easy thing to be too premature in one's remarks. There is a great deal of shouting before the edge of the wood is reached, and we have kept clear of this subject till we felt sure that hoary King Winter had been succeeded by the Spring Queen.

The calendar lines for to-day are very apt, but of course Tennyson was a close observer of Nature.

The damp hill slopes were quickened into green,
And the live green had kindled into flowers,
For it was past the time of Easter Day.

We say advisedly "the wonderful winter," for in all our memory we cannot recollect one less shrewd and rough. We looked for a change of weather at the autumn equinox, but lo! the change was for the better, not for the worse. A lovely Michaelmas, a perfect October, to all intents and purposes frostless and dry. The outdoor Chrysanthemums flowered themselves to death. November's days were by no means what they generally are—dark they must be, as there is no power to detain the sun; but drear they were not. We kept thinking St. Martin

would be ushered in with snow and frost, but he came and left again with a smiling face. Christmas drew on. There was a question as to how bacon would cure in the mild, tepid atmosphere, but the wisecracks said, "Oh, by the time the pig is killed and cut up, the weather will be sharp enough;" but it was not. We do not live in the sunny South, but in a cold, bleak district of—never mind where; and yet there was only one day on which the ponds bore, and that was December 25th. Alas! by Monday all trace of ice had gone, and young and old pleasure seekers were grievously disappointed.

It is not often we lie awake in winter thankfully listening to the rain on the window pane. Time after time the clouds gathered up, and we hoped for downfall of some kind—snow, of course, being expected—but no, the clouds rolled off again. It is rather a strong record—in our diary—only three wet days in December, and the entry "beautifully fine" occurring so many times, and a rain spoken of as "opportune." It must have been greatly desired.

We have noted for long that January is often a dry month, except there be heavy snowfalls, but although at times the sky was leaden the air was never really cold, as it is before coming snow, and the snow never did come, and the rain but seldom. There may have been two rainy days, and possibly a heavy shower or two, but that was the outside. No work for plumbers; no slack time for men or horses.

One does not often dawdle about in the garden for pleasure in January, but bright sunshine and fresh air are very tempting, and the garden never had a wintery look.

Who has not heard of snow pancakes for Shrove Tuesday? Well, those who waited for snow to make that delicacy will be waiting still. The situation was in February getting serious—no rain, no frost to mellow the land, and worse than that, the watercourses were all dry and springs failing. With dry watercourses in February we could only hope the blustering winds of March would prove damp winds. The 1st came stormy winds and whirling snow—not to stop—evening saw all clear again, and bright as a May day. On the 15th we thought we were in for a change, and were thankfully getting wet—only just a little top moisture, enough to vex without doing material good. On the 23rd the bright weather left us, and then came bitter blasts; but, alas! the rainfall was still very light. We had never felt so miserable for months. Talk about the skinning process; why, you had only to walk across the garden to be literally flayed. Happily this state of things did not last long, and we really suppose some coarse weather was our due.

By April 1st the sun again was in the ascendant, and Good Friday broke a peerless day; blue skies, balmy breezes—so soft, so mild, so glorious. For pleasure seekers Easter Day was not so perfect, so we hailed the showers with acclamation, and the steady downfall of Monday, followed by a "droppy" week, has put us all in good trim.

Dwellers in town have little notion perhaps as to the extent of this last winter's drought. Dry winters they do not look for and do not understand; but to country folks, who have water to lead for stock in February, the prospects are ominous. But for this anxious care for the future we should have engaged every hour of the past winter. Perhaps we are too tender, but the cold does so nip, and this year there has been such abundance of fodder and roots that there has been enough and to spare. The bodies of our stock have been warm inside and out, and that is a very comforting reflection to the owner.

From October 1st to March 31st there were 110 warm days, twenty-eight of which fell in January. March stands at the head of the cold months. December was the only month of the six with anything like an average rainfall, and even these rains were exceedingly partial in their nature.

During the last half century there have only been two winters with a smaller rainfall, and they were those of 1879–80 and 1858–9, and in the same period only four warmer ones. To one set of sportsmen this dry winter has been a great nuisance—we mean the hunting fraternity. Several early meets had to be postponed altogether because the "going" was so fearfully hard, and even when things got into full swing men and horses experienced much damage and much hard knocking about. Horses' legs will not stand ground

as hard as a turnpike, and most men like at any rate to fall "soft." If the beginning were bad, the end was even worse, and many packs had to make a premature finish. We wonder if this year the Beaufort hounds will kill their annual May fox.

Good comes out of evil, and the demand for sound horses has been brisk. There is, we fear, many a good hunter who will spend this summer in retirement with a very doubtful chance of being fit for work by next November. Well, perhaps a "short life and a merry one" is not to be quite despised. This year in Bodo, N. Norway, up to January 20th there had only been two days when sledging was possible. Let us hope that the winter season of 1898–9 will not be Arctic in its severity, things and weather in particular do so love to go by the rule of contrary!

WORK ON THE HOME FARM.

Since last week we have had a change of wind to the east with sunny days and frosty nights; the dust is blowing in clouds past the window as we write, and we are beginning to think a little more rain would be very useful. Wheats are looking grand, and some are so big that harrows have little effect on them. The dry weather has made the harrowing go very well, these big Wheats could hardly have been harrowed under other conditions of weather. We have put a little more Barley in, and have now finished for the season. This last did not go in too well; the land was a bit strong, and recent sheep treading had made it very knotty.

The outbreak of war between Spain and the States has caused a boom in food stuffs. We are taking the chance of a clear-out of Potato pies, and have got all the spare seed off to market to be sold as seconds, whilst our last pie of ware has been sold at £6 per ton (on rails)—a very satisfactory clear out.

The hum of the thrashing machine has been more prevalent than is usual in April, so it seems that farmers are wise enough to see the advantage of selling their remaining stocks of Wheat whilst the market is on the rise.

Stoppage of American meat supplies is likely very shortly to raise the price of beef and mutton, in fact a rise has already begun. It would, therefore, appear that now is the time for the grazier to use artificial foods to assist the pastures in bringing stock to maturity, whilst home productions may have command of our markets.

We are having an excellent opportunity given us now to complete the cleaning of fallows. Few fields within our knowledge require more than one dressing over with drag, roll, and harrow to make them agriculturally clean.

Small seeds may be, and often are, sown amongst spring corn after the latter has come up. Where the land is very apt to produce weeds the practice is a good one, as the necessary harrowing, whilst covering up the small seeds, will destroy millions of small weeds. The Barley or Oats must, however, be well up and be fairly strong. The weather, also, must be dry, as spring corn will not stand harrowing wet. The weed question apart, we think that Clover and grasses should always be sown with the corn, as it is much the safest way to secure a good plant.

OUR LETTER BOX.

"Strong" Butter (E. A.).—Your letter shall have attention. It arrived one post too late for enabling an answer to be published this week.

REMARKS.

24th.—Brilliant all day and night.
25th.—Cloudy early, and occasionally during the day.
26th.—Overcast morning; frequent sun from 0.30 to 4 P.M.; showery from 5 P.M., and steady rain from 7.30 P.M. to 10 P.M.
27th.—Gleams of sun in afternoon, but generally overcast, and foggy and gloomy early and in evening.
28th.—Rain from 3 A.M. to 8 A.M., and dull drizzly morning; fair from noon, and sunny from 3 P.M.; cloudy night.
29th.—Overcast and dull morning; alternate cloud and sunshine in afternoon, with occasional slight rain.
30th.—Overcast, with almost continuous spots of rain or drizzle till 2 P.M.; generally sunny after 3 P.M., and clear night.
Another average week, but with a little more (and very welcome) rain towards the end.—G. J. SYMONS.

IMPORTANT NOTICE.

We very much regret to state that our Shop and Offices at Exeter Street, Strand, have been destroyed by Fire, but we have every facility at our Warehouse in MERCER AVENUE to carry on our business as usual, and are in a position to give our prompt attention to all orders on receipt, and despatch same day.

Kindly address for the present to—

Mercer Avenue, Neal Street, Long Acre, W.C.
WATKINS & SIMPSON.

Packet, free for cash.

HOOPER, Pansy Grower, BATH.

COOLING & SONS' NEW ROSES FOR 1898.

NEW HYBRID BOURBON, PURITY.—Card of Commendation, National Rose Society. A grand New Rose, colour pure white with faintly flushed centre. As a Pillar and Garden Rose, and as a variety to cut for market work, it is bound to become a great favourite. Strong plants, 7/6 each.

NEW H.P. ROSE, R. B. CATER.—Another of the late Mr. Hy. Bennett's seedlings, a grand addition to its class; colour bright magenta-carmine, most beautifully shaded. Strong plants, 7/6 each.

NEW RUGOSA, DELICATA.—An exceedingly pretty and distinct new seedling Rugosa, which will be found a welcome addition to Garden Roses; colour, soft rose, double flowers of good size, blooming continuously, and in clusters. Strong plants, 3/6 each.

We have a large collection of Tea-scented and Garden Roses of all kinds in pots. New May List, post free.

GEO. COOLING & SONS,
THE NURSERIES, BATH.

STOVE & GREENHOUSE PLANTS, FERNS, &c.

Buyers of these are invited to inspect one of the largest stocks in the Kingdom of well-grown, clean, healthy plants in various sizes and immense variety at **OLDFIELD NURSERIES, ALTRINCHAM.** COLLECTIONS (our selection only):—12 vars. Flowering Stove Plants from 18/-; 12 vars. Foliage Stove Plants from 18/-; 12 vars. Greenhouse Plants from 12/6; 12 vars. Caladiums from 12/-; 12 vars. Crotons from 24/-; 6 Epiphyllums from 7/6; 12 distinct named Gloxinias from 18/-; 12 distinct Ferns for Stove from 9/-; 12 ditto for Greenhouse from 6/-; 12 different Adiantums from 6/-; Seedling Ferns for Rockeries, &c., from 3/- per doz. CATALOGUE, with description, prices, cultural hints, post free.

CLIBRANS, Altrincham and Manchester.

CARTERS' HOLBORN PRIMULA.—Our Prize Strain of the beautiful winter-flowering conservatory plant is the finest in cultivation. We were the originators of the blue variety now so popular. Fresh seeds, in all colours, mixed, including white, scarlet, blue, and pink. In Sealed Packets, price 2/6, 3/6, and 5/- each, post free.

CARTERS' BRILLIANT CINERARIA.—The very finest strain ever submitted to public notice. Awarded Highest Prize, Medal Royal Botanic Society, 1897, Royal Horticultural Society, 1898. A customer recently sent us blooms measuring 3½ inches across. Fresh seeds, all colours, mixed. In Sealed Packets, price 2/6, 3/6, and 5/- each, post free.

CARTERS' VICTORIA CALCEOLARIA.—Our grand strain is the very perfection of scientific culture, being compact in habit, and brilliant in colour and size of blossoms. A customer writes: "The plants were a perfect picture, many with 600 blooms; we took first prize." Fresh seeds, all colours, mixed. In Sealed Packets, price 2/6, 3/6, and 5/- each, post free.

CARTERS' INVINCIBLE GLOXINIA.—We have brought this fine summer decorative plant to the highest excellence. H.R.H. the Princess of Wales greatly admired our exhibit at the Temple Exhibition last summer, and was graciously pleased to pronounce it an "exquisite display." Fresh seeds, all colours, mixed. In Sealed Packets, price 2/6 and 5/- each, post free.

CARTERS', THE QUEEN'S SEEDSMEN,
237, 238, and 97, HIGH HOLBORN, LONDON.

DEFY THE BIRDS by Buying our Noted **ROTLESS TANNED NETTING**, as supplied to the Principal Gardeners in the Kingdom. Orders over 5/- value are sent Carriage Paid. 100 yds. by 1 yd., 3/-; 200 yds. by 1 yd., 6/-; 300 yds. by 1 yd., 9/-. Can supply any length and width. — **UNIVERSAL SUPPLY ASSOCIATION**, East Street Works, Reading. (Name Paper.)

HEATING APPARATUS.—Medals 1875 and 1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2/6; post free, 2/10.—**JONES and ATTWOOD**, Stourbridge.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd., Leeds.**

LONDON FERN NURSERIES,

LOUGHBOROUGH JUNCTION, LONDON, S.W.—Ferns, large and small, in variety; Aralias, Grevilleas, Cyperus, Ficus, Ericas, Palms, Dracenas, Aspidistras, Hydrangeas, Pelargoniums, Fuchsias, Marguerites, Crotons, &c. Trade, send for Wholesale List. Special List for Amateurs, send for one.—**J. E. SMITH.**

TOKYO NURSERIES CO.

HEADQUARTERS FOR
Japan Lilies, Cycas Revoluta
Morning Glory,
and all kinds of Japanese
Plants, Seeds, &c., &c.
Large Assortment always in
Stock. Orders promptly.

Journal of Horticulture.

THURSDAY, MAY 12, 1898.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St. London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

MAY FLOWERS.

AS the seasons come and go so do the flowers. They pierce the soil, bud, and flower, and pass away for the year. The Snowdrop has gone; the Crocus has followed suit; the early Scillas keep them company in their green array—soon to yellow with age before it is cleared away. These have gone with other early flowers, but there has come in their place a brave procession of the beauties of the time. The Snowdrop and the Spring Snowflake no longer droop their pure flowers, but the Summer Snowflake, taller, if less beautiful, nods upon its tall stems. The Crocus has vanished, but the Iris has come. The early Squills have fled from the brighter sun, but the Spanish and the nodding Scillas take their place. The Trumpet Daffodils have nearly left us for the year, but after them have come the pure discs of the Poet's Narcissus, with its fiery margined cup. We need not further elaborate the thought, but glance for a moment at the gay scene before us in the palace of Flora.

Fragrant and beautiful are the starry blossoms of Magnolia stellata. Pure do they seem as we stand a little away, but as we look more closely we see they bear a tinge of blush. One of the neatest and best of the Lily Trees for the rock garden is this species, and worthy to be grown where flowering shrubs find a welcome place. Not far off is the little Almond, known to botanists as *Prunus nana*, but perhaps more familiarly to gardeners as *Amygdalus nana*. For once we find the name recognised as correct more easily spoken than that more familiar. Pretty is this dwarf shrub, with its branches wreathed with pinkish flowers.

Ere the Daffodils have gone the Tulips have come. It is long since some appeared in bloom, but it is in May the greater number charm us with their perfect form and brilliant hues. It is pleasant to see them again in greater favour. In groups among other plants in or out of flower they please us better than in formal lines or beds alone. Delightful are their colours: white, scarlet, crimson, rose, pink, yellow, orange, white, parti-coloured, striped, margined. Who can in brief space tell the colours and combinations they show?

Drooping from the rock-garden's slopes is a fountain-like bush of green and cream, or perhaps more truly creamy white and green. Attractive is it a little way off, but if we go nearer we find it more beautiful still from its flowers possessing the favourite form of the leguminous plants. It is *Cytisus præcox*—the Cream Broom, a hybrid raised at Warminster by the late Mr. George Wheeler some thirty years ago. It is presumably a hybrid, although this is not certain, as it was found in a bed of seedlings of *C. purgans*, but it has been suggested that it is between that species and *C. albus*. However this may be, the Cream Broom well deserves to be grown in the rock garden or the shrubbery, where its wand-like branches covered with pale sulphur blooms can be appreciated. For a rather dry and sunny spot few prettier plants can be found for blooming in the end of April or the beginning of May.

The snowy *Arabis* is getting past its best just when the purple *Aubrietias* claim its comradeship by way of contrast to their colours; but though the *Arabis* forsakes them, the *Aubrietias* have purer companions in some of the Candytufts, whose sheets of white glisten on the rockwork or in the border. There are pink *Iberises* such as the Gibraltar Candytuft; but these are not so much admired as the white species and their varieties. Delightful are the mounds or curtains of white made by the larger growing plants; but for a choice place none would be more acceptable than the variety known as Little Gem. Only 3 or 4 inches in height, a miniature *Iberis sempervirens*, it is of great beauty, and nestling here a little lower than the beautiful *Rhododendron ciliatum* it has come into bloom when this alpine Rose has lost its flowers, and has given a new feature and a new attraction to the spot.

In a shady border, half hidden by the leaves and flowers of the ubiquitous *Claytonia caroliniana*—which, like a weed, has invaded its domain—is a clump of the modest little Canadian Violet, *Viola canadensis*. Small are its blossoms, faint is its perfume, modest its colours, yet its simple beauty compels admiration, even though near it grow some of the modern *Violas*, more opulent perhaps in their charms. As one looked just now at its dainty little white flowers with yellow eye, a few short purple rays, and with two of the upper petals coloured with purple on the back, there was espied beside it a single bloom of a tiny fellow flower of the little golden *Viola biflora*. Two years ago these plants of the Canadian Violet bloomed in Ontario; last year and this year they look equally happy in fair Scotland among sisters from other lands. A garden of hardy flowers is a little cosmopolis—one, too, in which flowers from many countries live side by side in harmony.

From North-West America comes the Celandine Poppy, *Stylophorum diphyllum*, whose blossoms are, perhaps, more welcome later in the year than now, when *Doronicums*, *Alyssums*, *Adonises*, and other yellow flowers are plentiful. As yet, however, there are hardly any of similar character in bloom, though in a few days the Welsh Poppy, *Meconopsis cambrica*, will be in flower. Like the latter, the *Stylophorum* appears to enjoy a little shade, and in a peaty soil thrives and flowers for some time. May is said to be its normal flowering month, but it generally anticipates its "book" date, and with April come its drooping yellow flowers above its glaucous, pinnatifid leaves. It is about 1 foot high. Since its introduction more than forty years ago it has made but little way towards becoming a common garden flower, though it is as easily grown as most of our cultivated plants.

These are a few flowers casually, as it were, selected from the array of the beauty of the dawn of May. It is almost bewildering in its variety—white and brown, and green and yellow, and chequered *Fritillarias*, sway in the wind; golden-eyed *Auriculas*, sweet *Primroses*, fairy *Cowslips*, bunched *Polyanthuses* shine from corners, slopes, and borders; rich golden *Doronicums*—the *Sunflowers* of spring—delight us with their many-rayed glooms; virgin-like *Wood Anemones*, with pale blue or sapphire sisters and their cousins, the *Crown Anemones* of more brilliant colours, open to the bright May sun; odorous *Wallflowers*, golden, blood red, deep brown, exhale delicious fragrance as the south wind touches their petals; the double *Marsh Marigold* (*Caltha palustris* fl.-pl.) shines by the edge of the Lily pool, where

buds of the *Nymphæas* begin to peer above the surface; arching heads of yellow blooms deck the big bush of *Vesicaria utriculata*, which will by-and-by be laden with its bladder-like seed vessels; the encrusted *Saxifragas* begin to send up their flowers, and the mossy species are in bloom, dark red as in *S. muscoides atro-purpurea*, pink as in *S. Rhæi*, or white as in the greater number; the *Forget-me-nots* are sheets of blue, as in the case of *Myosotis dissitiflora*, or budded for bloom as with some of the later species.

Many more flowers there are seeking to rival or enhance the beauty of the blossom of the trees, which are robed in the perfection of flower and leaf. The fair pages of the book of Nature are open before us. Let us joyously, thankfully, reverently study them, that our hearts may be cheered, strengthened and uplifted by the messages they bear.—S. ARNOTT.

NOTES ON MELONS.

It may be prejudice that prompts my conviction of the best Melons being grown in pits and frames, and of my not considering the present varieties any advance on the remarkably fine-flavoured Egyptian and delicious Persian, with the sugary Scarlet Gem. I may be wrong, but I certainly never find the palate satisfied by the Melons of the present time. That may be my misfortune, but will any grower tell us of any three modern varieties that come anywhere near the three named in green, white, and scarlet flesh respectively?

Perhaps no fruit is easier to grow than the Melon, and certainly not any worse produced at the present day. The majority are worth little, and cannot well be eaten without sugar, than which no greater condemnation can be evidenced. Is it that the advantages of the hot-water system are delusions, and the disadvantages of the fermenting material mode of culture the ideals of successful Melon production? When fermenting materials are well prepared, so as to be moist whilst fermentation is going on, the bed affords a steady supply of moisture to the roots. This is of great importance in a dry season, and points to Melons on the hot-water method not having enough or an irregular supply of water at the roots to account for their indifferent quality. Some of the old gardeners never watered their Melons after they were thoroughly established, for the simple reason that the plants did not require any after the roots struck into the moist fermenting materials. I have tried that many times, and found it answer admirably in some cases, but just as badly in others, so that the gist of the subject resolves itself into a matter of judgment and adaptation of practice to circumstances.

There need be no difficulty about procuring stable litter, as it is not much wanted as manure at this season, and there ought to be leaves if care has been taken to preserve them. Any old stuff will do, with just a "freshener" of stable litter to keep the whole compact, and to make up a bed about 3 feet in height on a place where the sun shines from rising to setting. I use the waste from Rhubarb and Seakale pots with any leaves left over, and a fourth of stable litter. A load of this will, therefore, put renewed "life" into three of spent material, and about a stone of kainit and two of basic slag puts heart into it for after work, as the stuff comes out quite mellow in autumn, and for top-dressing borders has no equal.

Seeds can be sown in small pots singly, and plunged in the bed, will shortly sprout, and the plants can be turned out when coming into rough leaf. But it is better to put a barrowful of soil in each light, and sow the seed as soon as the heat has warmed it. One plant in the centre of each light is better than two. The soil cannot be too firm, and it should be highest in the centre of the light, forming a very gently inclining mound, and covering the whole bed with soil.

COMPOST.

The best I have ever used for Melons, and that was in 1851, consisted of the top 3 inches of a rich alluvial pasture, overflowed in winter by the river giving the name to Wharfedale. That is near enough as to location, and nothing was added to it. Since then I have found pigeons' manure added to good strong loam make Melons grow, and even fowl manure is better than that from cows, stables, or farmyards. I regarded the pigeon manure as a discovery, and was going to send a note to the *Journal* in its *Cottage Gardener* days, but found it had been used in Persia for the growth of Melons "from time immemorial." Any good garden soil will grow Melons, especially with half a peck of pigeon refuse added to a barrowload. I found, however, that fowl house manure, where gypsum had been used for "sanding," answered even better, using a peck to a barrowload of soil. The point is to mix well, and place in compactly when neither wet nor dry, but in a pleasantly moist condition.

TEMPERATURE.

The heat from the bed seldom makes the soil hotter than 90°, just right for holding the hand in comfortably, and to make Melon seed push radicals or tap roots into the soil and bed. The cotyledons, or first leaves, open out boldly to the sun, and are broad, stout, and deep green. The stem may be an inch high and accord in thickness. Only

give a little air at 75°, and to 90° with sun. A mat over the light at night will prevent the heat falling below 65° in the morning, and by uncovering early the plants will grow sturdily. There must be no drawing up; most Melons being ruined before they reach youth by giving as much, or more, heat than is required to ripen the fruit. It is well, however, to observe more natural conditions. I give a little air at 75°, and let the heat rise as near 90° as possible while daylight lasts, closing early in the afternoon right through the season.—EXPERIMENTALIST.

(To be continued.)

PROFITABLE FRUIT GROWING.

(Continued from page 386.)

ABOUT the temperatures best suited to the Vine, I would say, speaking generally, that to get a high colour in white Grapes you must have a higher temperature than what is required for black. As a rule you cannot put high finish on black Grapes with hard firing. I know of two instances—one with Lady Downe's, the other with Gros Colman—where they were grown at the bottom end of houses which had a considerable rise. Owing to the cooler position they were always the last in the house to be thinned, and often quite a month behind others of the same kinds in the same place; but they were always the first to be black, and generally better finished than any of the others. I do not believe in any set temperatures to be scrupulously observed at set periods of the Vine's growth—such as 70° at night for Muscats, and so on. Go more by the weather and the health and constitution of the plants. A good and safe plan is to have sufficient pipes arranged in the house, and keep them warm but never hot, and the temperature will generally be right. Guard against fire heat on bright days, then the pipes cannot be too cool. Another point is not to wait until the temperature has fallen, but have it ready to keep up the heat, bottled as it were from the sun as long as possible. I consider a temperature of 70° too high if from fire heat. A high night temperature is weakening to most plants, the same as sleeping in close warm rooms is weakening to the individual. From a night temperature of 60° Vines will rise fresher and fitter for their day's work. No higher is required to set the most difficult kinds. I know Muscats, both Canon Hall and Alexandria, which are well set annually with an average night temperature of 55°. One other point in connection with heating—the arrangements of pipes. The sole use of pipes in any hothouse is to give off heat for the benefit of the occupants of the house. This should be noted and remembered, and made the first consideration. Other matters which are of secondary importance, such as where they will look best or be most out of the way, are often placed first. Now, anyone can see that the more the pipes are spread over the border, the better and more regular will the heat be distributed—not too hot here and too cold there. I would strongly recommend this plan not only for Vines but other crops as well. The inconvenience in working is only in name.
